Time and again we are told by those best qualified to know, that it is not the skilled artisan, or the clever professional, who are wanted in South Africa, but the man with at least some few hundreds capital. Horticulture (I do not mean that kind which grows Cauliflowers at 1s. 6d. a time, although the exigencies of bread and butter for the wife and weans may compel us to resort to it, and which in no way do we wish to pooh, pooh) horticulture, I take it, is the natural outgrowth of a prosperous, not to say luxurious age, and which, from the professional point of view constitutes its great weakness. When the Rhodes, Beits, Barnatos, &c., have made their millions, they commence buying or building mansions, acquiring estates and works of art, and forming gardens, but mark you, not in South Africa, nor are there yet any indications of them so doing. Those who are in South Africa are there not with the idea of spending money, but of making it, either out of the necessities of life, or out of other peoples' labour—this latter infinitely the easier plan to the capitalist. Even in America, a country of much older growth, it is only within recent years there has been so much progress in the direction of high-class gardening. Of course, it might be that our horticultural emigrant would be content to find temporary employment underground in that horticultural paradise (I believe white men are now being given a monopoly in that kind of work at 5s. a day, and which sum, I am told, will purchase a very respectable dinner, I don't want any awkward questions asked about the other meals), and in which work, although intimately connected with the soil, he would hardly find bearing for his "Cabbage-like learning," but we reflect, had he "sedulously imbibed" of the waters of geological and perhaps metallurgical research, he might much sooner be in a position to acquire the necessary capital for his big horticultural effort. To some of us, eminently practical perhaps in other respects, gardening is not altogether a means of obtaining bread and butter, but a kind of terrestrial heaven, in which we find a species of happiness unobtainable outside of it, and the thought of an existence other than along the road on which we have been travelling, and at the end of which we hope to attain our ideal, or something approaching it, would be extremely painful, and that is the reason why we keep pushing on and—NEVER DESPAIR.

### Horticultural Lecturing and Judging.

As autumn is now fast approaching when County Councils and other bodies will be busy selecting men as horticultural lecturers, I think this an opportune time to impress upon them the necessity of selecting men of practical experience, consequently who know what they are talking about. Of course, I am fully aware that the great majority of men so engaged are the right men in the right place; at the same time I have in my mind an instance of a man engaged by a public body in the Midlands to go about lecturing on horticulture to amateurs and cottagers, and who even has the audacity to judge at flower shows, who never had a month's training in a good garden in his life, neither amongst vegetables, fruit (inside or out), nor yet the simplest forms of stove or greenhouse plants. That these public bodies are innocent of any intention of selecting any but the best men I verily believe, but not, in many instances, being practical horticulturists themselves, they are too often carried away by high sounding titles, the "gassy" utterances and assuming manners of applicants, instead of subjecting them to a severe practical test, in which case their ignorance would be demonstrated, and amateurs and cottagers would be saved the trouble of listening to men whose horticultural knowledge is less than their own. The same remarks apply to judging at flower shows, I mean the smaller flower shows; because I know the larger ones are managed by men of experience, whose judges are experts at growing the things they are called upon to judge; but not always so at these smaller shows, which are often managed by men of business, who have a commendable love for their garden, and are ardent supporters of horticulture. These men, I have no doubt, are sometimes unintentionally carried away by the alluring title of F.R.H.S., &c., hence the mistakes occur that I have alluded to, mistakes which, in the interest of horticulture, it is always wise to avoid. The importance of a wise expenditure of public money, and the putting of the right men in the right place, is my only excuse for troubling you with this epistle.—HORTICULTURIST.

### The Destruction of Unhealthy Plants.

Mr. J. Ollerhead, an old Journal correspondent, whose paper on the Microscope may have been read with interest by many, writes as follows:—"I would be glad to know if any of your readers has any experience with the pests *Macrobolus Hufelandi* and the *Oribata demersa*, which are quite new garden enemies to me. At the same time I have been for years convinced that thousands of plants are annually consigned to the rubbish heap both by gardeners and nurserymen, and too often a great many of them of considerable value, and that without knowing the cause of their disease or unhealthy condition. The cultivator, or the man in charge of them, gets the credit of neglect or unscrupulous use of the water-pot, whereas, if the plants were submitted to a thorough investigation of the microscope, the hidden mysteries of insects or disease would be revealed in such a way that would exonerate the cultivator from the slightest tinge of blame. If you think it worth while to ventilate this through your columns, it may be the means of benefiting both the employer and cultivator, and cause the former to make a closer investigation before blaming the latter, and thus do a public service in the right direction." Has Mr. Abbey, or any scientific reader, any experience with the subjects named by our correspondent?

### High Jinks in Ireland.

I beg your pardon, Mr. O'Neill! That puts us right at starting. But is it possible? Can it be, I wonder? Ahem! Excuse my "imperence," but is there not a little—a very "leetle" mistake anent that picture of *Cordylina australis*, on page 205? I hear that you have had high jinks in Ireland. Your unique horse show; your admirable flower show; fine sport on your splendid new racecourse at Ashtown; good running on the excellent old one at Leopardstown; and a new Lord-Lieutenant you have got, or, at least, will have him when you get him. Why tarried the wheels of his Excellency's chariot when he was so much wanted for the gala week? Oh! it was rare old times, I hear, and what with "purty" colleens hovering about, potteen flying around, and elegant Potatoes at sixpence per stone, small wonder that the littlest of little errors might creep into Irish correspondence. But, mind, I don't say it did; yet, certain sure, that *Cordylina australis* both in foliage and flower is different to the many fine specimens seen during a prolonged visit to the Emerald Isle. The foliage, as depicted, is so much like *Dracæna Lindenii* (stove plant), and the flower spike so much unlike those heavy, drooping, massive, ramified heads usually borne by *D. australis*, that I think—I thought—it possible, just barely possible, you know, that a little, very little, error had crept in. Then, too, the camera, I have been told, is an awful l——r. It is, I believe, not guiltless of telling a few, judging from the view taken of a small pond, where each yard of its length appears as a mile in the photo. Anyway, I don't want any blackthorns humming around, so if I am wrong, I beg your pardon, Mr. O'Neill, and that puts us right at the finish.—Quiz.

### Plan Drawing Competition.

Enclosed is an advanced copy of our competition for under gardeners for next year. Whereas the piece of ground last year was 20 acres, that this year is about 3 acres. I found that last year some people read the description as indicating an actual piece of ground. Both last year and this year the plan is wholly imaginary. I shall be very glad if you will again make this matter public in the interest of the young men for whom the competition is intended.—P. MURRAY THOMSON, Secretary to the Royal Caledonian Horticultural Society, 5, York Place, Edinburgh.

We print the instructions for the plan competition as follows:—"For a plan, drawn to scale (16ft to inch), for laying out a piece of ground about 3 acres in extent, as shown on the sketch plan, which the secretary can supply on application to him. The dotted contour lines show the elevations, in feet, of the ground to be laid out and of the adjoining properties. The ground is to be laid out suitably for a suburban residence garden. The glass may be conservatory, forcing-house, and cool greenhouse, with the necessary frames, heated or unheated; and the fruit house is to be either vinery or Peach house, in the option of the competitor. A lodge may be provided as a gardener's house, or a gardener's house may be placed otherwise, or in addition to a lodge. The estimated cost of laying out is not asked for on this occasion, but in future it will probably be required. First, 60s.; second, 40s.; third, 20s. The first and second prizes are given by Sir John Gilmour, Bart., Montgrave, and the third prize by the society. On each plan there should be a short explanatory key. Each plan and description must bear a motto and be accompanied by a sealed envelope bearing the same motto and enclosing the competitor's name and address. All plans for this competition must be in the hands of the secretary, Mr. P. Murray Thomson, 5, York Place, Edinburgh, not later than April 1, 1903."

# NOTES & NOTICES

## An Observer's Notes.

I have for many years noted that very rarely do we see the swift after about August 10, 11, or 12. I saw one as late as the 25th this year, which, I think, is unusual.—A. BAKER.

## Appointment.

Mr. Alexander McMillan, till recently, and for four years, the successful Chrysanthemum and Rhododendron grower at the Camphill Houses, Queen's Park, Glasgow, as superintendent of the Christie Park, Alexandria, N.B. His many friends will wish him success in his new charge.

## Decrease in Hop Cultivation.

According to a return just issued by the Board of Agriculture the acreage under Hops this year in England is only 48,024 acres, as compared with 51,127 and 51,308 acres in 1901 and 1900 respectively. Of the nine counties specified Suffolk stands at the bottom of the list with 4 acres only, the same as in the past two years; Gloucester has 46 acres, the same as last year, and 1 acre less than in 1900; while in Kent alone the falling off amounts to about 1,400 acres.

## Mearns Horticultural Society.

The forty-third annual show of the Mearns Horticultural Society was held recently at the Public Hall, Newton Mearns, and again proved a distinct success. This old established show still holds its place as one of the foremost in Scotland. The prominent feature of the show this year was a magnificent show of Roses by Mr. Hugh Dickson, Royal Nurseries, Belfast, consisting of over 150 splendid blooms, and was deservedly awarded the gold medal of the society by the judges, who expressed their unqualified admiration of this splendid exhibit.

## Torquay District Flower Show.

The Committee of the Torquay District Gardeners' Association regret that, owing to lack of funds, they are compelled to cancel the schedule for the annual Chrysanthemum show fixed for November 5, with the exception of the special prizes, classes 29—33. It is, however, intended to hold a show on the same day for honorary exhibits, and it is hoped that the friends and supporters will endeavour to send as many exhibits as possible in order to make the show a success. For any further information apply to Geo. Lee, Hon. Assist. Sec., The Lodge, Upton Leigh, Torquay.—R. P. KIRSON, Hon. Secretary.

## Death of Mr. James Percival.

Many readers of the Journal will learn with regret, more especially those residing in the border counties of Lancashire, Yorkshire, Derbyshire, and Cheshire, of the death of Mr. James Percival, who up to the time of his decease was one of the most impressive figures to be found at the various gatherings of botanists held in the above counties. For a great number of years he was president of the Manchester Botanists' Association, and a useful and highly respected member of the United Field Naturalists and kindred societies. Mr. Percival belonged to a family imbued with a strong love of Nature, and possessing, one may say, an instinctive desire to understand thoroughly the forms of life by which each was surrounded, his grandfather being one of the pioneers of the scientific study of botany in Lancashire, and from him Mr. Percival inherited his strong desire for the complete study of plant life. He possessed a most remarkable memory; a plant once seen by him was never forgotten. He was a modest, but a most ardent botanist, delighted and ever ready to impart to learners, with fluency and accuracy, both the English and Latin terms for the species, genus, and order of each floral specimen, the origin of its common name, habitat, medicinal qualities, or some hoary superstition that may be attached to it. He travelled in his spare time over the greater part of the British Isles in search of plants, and cultivated in his garden at Smithy Bridge, near Rochdale, many of the rarities he had gathered in his rambles. He was laid to rest at Prestwich, at the ripe age of seventy-four, in the presence of many friends and fellow botanists, on the 21st ultimo. "He had no favourite flower, but loved them all."—J. N. M.

## Our Bulb Number.

The bulb number, of which particulars are published on one of the advertisement pages in the present number, will appear on September 18, and not in conjunction with the report of the fruit show held at the Crystal Palace. The alteration will allow greater space for our illustrations of bulbous plants and flowers, and the articles of a special nature in connection with them. It will allow free our pages for the fuller reporting of the Palace show, and matters pertaining to fruit culture.

## Crystal Palace Fruit Show.

The Royal Horticultural Society's great show of British Grown Fruit takes place at the Crystal Palace on Thursday, September 18, and the two following days. Copies of the prize schedule with entry form can be obtained on application to the secretary, R.H.S., 117, Victoria Street, Westminster. Intending exhibitors must give notice in writing not later than Thursday, September 11, of the class or classes in which they propose to exhibit, and the amount of space required. On each day of the show after 10 a.m. Fellows of the Society on showing their tickets at the turnstile will be admitted to the Palace free.

## Temple House Gardens, Great Marlow, Bucks.

The register of rainfall here for August, 1902, was 3.65in; the highest maximum was 78deg on the 28th, and the lowest minimum 43deg on the 1st. The highest maximum for August, 1901, was 83deg on the 10th, and the lowest minimums were 44deg on the 10th, 21st, and 28th. The rainfall for August, 1901 was 2.35in. There was thunder on the 19th, heavy showers on the 6th, 7th, and 26th, a foggy morning on the 26th, and a very dense fog on the 27th. We are on the banks of the River Thames, and 105ft 9in above sea level.—GEORGE GROVES, Temple House Gardens, Great Marlow, Bucks.

## Sussex Weather.

The total rainfall at Abbots Leigh, Haywards Heath, for the past month was 4.18in, being 1.77in above the average, the heaviest fall was 1.15in on the 18th; rain fell on twenty-one days. This record was exceeded in August, 1891, when 5.83in fell on twenty-five days, with a very much lower mean temperature than we have had this year—viz., 57deg, and again in August, 1881, with a fall of 4.63in. The maximum temperature was 80deg on the 16th; the minimum 42deg on the 2nd. Mean maximum, 70.22deg; mean minimum, 52.27deg; mean temperature, 61.24deg; which is 0.19deg below the average. The rainfall this month has been more remarkable for its persistent small quantities than for the amount as a whole. It has been favourable for the growth of green crops, and that is about all. Harvest has been in slow progress for some weeks, very little yet carried, and I fear much of the corn will be only fit for feeding purposes.—R. I.

## Croydon Gardeners' Outing.

The annual outing of the Croydon Gardeners' Society took place on August 27, the places selected being Paddockhurst and Worth Park, Sussex. The members left Croydon at 8 a.m. by brakes, and after a delightful drive of twenty-three miles, arrived at Paddockhurst, where they were met by Mr. Wadds, gardener to Sir Weetman and Lady Pearson. Mr. Wadds escorted the party through the beautiful gardens and grounds under his charge. Note was made of many objects seen about. Before leaving, three hearty cheers were given Sir W. and Lady Pearson for their kindness in permitting the members to visit their charming place; also to Mr. Wadds for his courtesy to all present. An adjournment was made to the Red Lion, Turner's Hill, where a capital luncheon was served. Here the health of Sir W. and Lady Pearson, and Mrs. Montefiore, of Worth Park, was drunk with musical honours. Luncheon over, a pleasant drive brought the party to Worth Park, where Mr. Allen, Mrs. Montefiore's gardener, received the members and piloted them through the beautiful garden and grounds under his charge. Many most interesting notes were made for future use at the Society's meetings. Before leaving Worth Park, three ringing cheers were also given to Mrs. Montefiore and to her courteous gardener. A drive to Horley brought the party to the Chequers Hotel, where an excellent tea was served on the lawn. After a rest here, the horses were put to, and a good drive homeward brought a most enjoyable outing to a close. The weather was all that could be desired.—J. G.

## Societies.

### Royal Horticultural—Drill Hall, Sept. 2nd.

Owing to the National Dahlia Society having the use of the Drill Hall, the meeting of the Royal Horticultural Society was confined to a few small exhibits of plants and fruit. A boxful of Victoria Apple, which somewhat resembles Lord Suffield, came from Messrs. Cross and Son, of Wisbech. Mr. G. Shawyer, Cranford, Hounslow, sent a number of fruiting branches of Tomato, Cranford Prolific, which well deserves its name. One of the clusters bore eleven full-sized and firm fruits. A Cultural Commendation was accorded. Some Melons were exhibited, but none call for comment. Sir Walter Gilbey, Bart., The Orchards, Elsenham, Essex, contributed four sorts of Cherry-Plums, the yellow, the red, and two seedlings, one a dark red, the other yellow.

Messrs. Grieve and Sons, Broughton Road, Edinburgh, sent their strain of bronze Violas, which are pretty on a sunny border, but are dingy in bunches for the table. Their seedling Dianthus, a semi-double, glowing crimson, floriferous novelty, was much admired.

Mr. C. W. Piper, The Nurseries, Uckfield, Sussex, contributed beautiful bunches of a new Tea-scented Rose, whose name a lady suggested should be "Peace." The Rose is somewhat like Mme. de Bravy—a very pleasing creamy colour. It is spoken of as "a continuous bloomer, early, midseason and late, resembling G. Nabonnand in habit, and is one of the best for massing."

Sir Trevor Lawrence, Bart., Burford, Dorking, sent *Onosma pyramidalis*, a grey, hirsute, upright growing species with drooping crimson flowers.

*Philodendron Corsinianum*, a handsome Aroid, from Messrs. Bull and Sons, Chelsea, received considerable attention. *Lindenbergia grandiflora*, with oval-acuminate, crenate leaves,  $4\frac{1}{2}$  in long, somewhat hispid, and axillary yellow flowers, was shown by Messrs. J. Veitch and Sons, Limited, Chelsea. It is showy, seen at its best, and good for autumn.

Only a very few Orchids, from various patrons, were brought forward. The other novelties are described below. A lecture on "Hardy Fruits in Yorkshire," by Mr. A. Gaut, was delivered in the canteen.

#### Certificates and Awards of Merit.

*Cattleya Schofieldiana*, *Hessle variety* (W. P. Burkinshaw, Esq.).—A handsome *Cattleya*, with large segments, greenish yellow, and brown spotted. (Award of Merit.) From The West Hill, Hessle, near Hull (gardener, Mr. Barker).

*Ceanothus Indigo* (Mrs. W. H. Burns).—Robust in growth, foliage dark and glossy, flowers in dense thyrsoid cymes, and of a bright indigo hue. From North Mymms Park, Hatfield (gardener, Mr. C. R. Fielder).

*Nymphaea stellata*, var. *Mrs. Ward* (Leopold de Rothschild, Esq.).—A great break in colour, a decided rose-magenta, the flowers the same size as *N. stellata*. (Award of Merit.) From Gunnersbury House, Acton (gardener, Mr. J. Hudson, V.M.H.).

*Rose Peace* (Mr. W. Piper).—A Tea-scented Rose, full in form, of a light creamy colour, with long reddish stems of dark foliage. It has the habit of *G. Nabonnand*. (Award of Merit.) From Uckfield, Sussex.

*Sterculia Russelliana* (Mr. J. Russell, Richmond).—A graceful foliage plant, reminding one of *Aralia Veitchii*. (Award of Merit.)

*Sweet Pea Dorothy Eckford* (Hobbies, Ltd.).—A pure white variety already described. (Award of Merit.)

*Thuia Ellwangeriana pygmaea aurea* (Charles Turner).—A round fluffy mass of growth. It is feathery, like *Retinospora plumosa*, though resembling a Juniper towards the base. A good dwarf shrub for winter bedding. (Award of Merit.) From Slough.

### National Dahlia, Sept. 2nd and 3rd.

Until Mr. Edward Mawley's Dahlia Analysis appears in the *Journal of Horticulture* next spring, growers will be unable definitely to tell how the various forms of the flower were exhibited as regards numbers, compared with other years, when the show was held at the Crystal Palace. As all who follow events are aware, the directorate of the Palace at Sydenham found it inconvenient to fulfil certain promises made, and the alternative is wrought out in the dissolution of the exhibitions of the National Dahlia Society from their hitherto pleasant quarters at the place named. The Drill Hall affords a poor substitute, which most will admit, because there is too little space, and the handsome displays set up by the nurserymen are so confined as to lose much of that imposing effect which they seemed formerly to have.

Again, the season has been remarkable in many respects, and though there may be no lack of leafage and stout, sappy stems, we are afraid the floral yield has suffered considerably from lack of dry, sunny weather. Colour all through the exhibition was deficient, and size was below par. Refinement, too, especially among Shows and Fancies, was a quality largely wanting. Looking from the balcony of the hall the scene was bright, very bright,

but our impressions of this show were not favourable, judged against past years. Single Dahlias were generally well shown, and the leading collections of Pompons, as of Cactus varieties, were very good.

#### Nurserymen.

##### SHOW AND FANCY DAHLIAS, INTERMIXED.

DIVISION A.—There were four entries in the class for forty-eight blooms of Show and Fancy varieties, distinct. Mr. J. Walker, High Street, Thame, proved the victor, having a good even exhibit, though it must be said they were not up to their usual form. The varieties were (reading from left to right): R. T. Rawlings, T. W. Girdlestone (self), Majestic, James Cocker, Rev. J. B. M. Camm, Rebecca (self), John Hickling, Purple Prince, Maud Fellowes, Grand Sultan (self), William Powell,

*Sternbergia lutea*. (See page 218.)

William Keith, Mrs. Morgan, Imperial, John Walker, and Daniel Cornish; second row: Arthur Rawlings, Marjorie, Chieftain, T. J. Saltmarsh, Sailor Prince, Mrs. Fisher, John Standish, Watchman, Victor, J. T. West, W. Rawlings, Florence Tranter, Duke of Fife, Flag of Truce, Plutarch (self), and Golden Gem; front row: Kathleen, S. Mortimer, Plutarch, Mr. Glasscock, Mrs. W. Slack, Dr. Keynes, Queen of the Belgians, John Bennett, Buffalo Bill, Mabel Stanton, J. C. Reid, Nubian, Mrs. Langtry, Duchess of York, Muriel Hobbs, and Mr. George Harris. Mr. S. Mortimer, Swiss Nursery, Farnham, was a good second, his best blooms being T. W. Girdlestone (self), Emin Pasha, Miss Cannell, Mrs. Foster, Duchess of Albany, Mrs. Saunders, John Hickling, Mrs. Morgan, Victor, Mrs. Stephen Walker, and Buttercup. Mr. W. Treseder, The Nurseries, Cardiff, brought up the rear with good blooms of Colonist, Chieftain, Rev. J. Gooday, Maud Fellowes, and William Powell.

For thirty-six blooms distinct there were again four competitors, Mr. J. Walker leading with well-developed blooms, though they were not so even as one expects to see at the national Show. The varieties were: R. T. Rawlings, James Cocker, Majestic, Daniel Cornish, John Hickling, T. W. Girdlestone (self), Seedling, Harry Keith, Mrs. C. Noyes, Champion Rollo, Mrs.

Morgan, Imperial, Arthur Rawlings, Queen of the Belgians, Duke of Fife, Mrs. Fisher, Chieftain, Mabel, Sailor Prince, Golden Gem, William Rawlings, Marjorie, Prince Henry, John Walker, T. J. Saltmarsh, Emin Pasha, Mrs. Emery, Lord Chelmsford, J. T. West, Joseph Ashby, Chorister, Duchess of York, Kathleen, Eclipse, Mrs. Gladstone, and Diadem. Mr. S. Mortimer was second with typical blooms of William Powell, Mrs. W. Slack, Mrs. Sanders, Perfection, Sunset, Nubian, George Rawlings, Duchess of Albany, John Hickling, and Warrior; Mr. W. Treseder taking third place with good flowers of Marjorie, T. S. Ware, Mrs. W. Slack, Mrs. Saunders, Agnes, and Prince of Denmark.

**DIVISION B.**—There were only two entries in the class for twenty-four blooms distinct, and the first prize was awarded to Messrs. J. Cray and Sons, The Nurseries, Frome, with a good exhibit, the varieties being Rev. J. B. M. Camm, Florence Tranter, William Rawlings, W. Powell, Mrs. Gladstone, Willie Garrett, Shottesham Hero, Chieftain, Matthew Campbell, Mrs. Saunders, Dr. Keynes, Mabel Stanton, Harry Keith, Mrs. W. Slack, Emin Pasha, John Hickling, T. J. Saltmarsh, D. Johnston, T. J. West, T. S. Ware, Excellent, John Walker, Mrs. J. Downie, and Mrs. Every. Mr. M. V. Seale, Vine Nurseries, Sevenoaks, was second, his best blooms being John Forbes, Mrs. Gladstone, Mr. Glasscock, John Walker, Crimson King, S. Mortimer, and Mrs. W. Slack.

The class for eighteen Show and Fancy varieties was only represented by two exhibitors, Messrs. J. Cray and Sons being placed first for a moderate exhibit. The varieties employed were T. S. Ware, Rev. J. B. M. Camm, W. Rawlings, Mrs. W. Slack, Emin Pasha, R. T. Rawlings, John Walker, Colonist, Mrs. Gladstone, J. T. West, William Powell, Mrs. J. Downie, Diadem, Mrs. Langtry, Matthew Campbell, Florence Tranter, W. Garrett, and Shottesham Hero. Mr. M. V. Seale again occupied the second place. His best flowers were Plutarch, J. B. Service, Mrs. W. Slack, Miss Cammell, Colonist, R. T. Rawlings, and John Rawlings.

**DIVISION C.**—Twelve blooms, distinct, were represented by one board, surely a poor display for the National Society, but Mr. J. R. Tranter, Henley-on-Thames, deserved the first prize which was awarded. His varieties were John Standish, John Hickling, T. W. Girdlestone (self), Champion Rollo, William Powell, Duchess of York, Florence Tranter, J. T. West, Dr. Keynes, Matthew Campbell, Earl of Ravenswood, and J. R. Tranter.

#### CACTUS DAHLIAS.

In the premier class for eighteen bunches of Cactus varieties distinct, six blooms in each bunch, there were four competitors. Messrs. J. Stredwick and Son, Silverhill Park, St. Leonards-on-Sea, was awarded first prize for a good strong stand, which was somewhat lacking in bright and dark colours. The varieties were F. H. Chapman, Tasmania, Eva, Vesuvius, Mary Farnsworth, Etna, H. J. Jones, Uncle Tom, Raymond Parkes, Mrs. Balding, Clara, H. T. Robertson, Mrs. Mawley, Bruce, J. W. Wilkinson, Clara G. Stredwick, Miss F. M. Stredwick, and Vesta. Messrs. Keynes, Williams and Co., Salisbury, were second with good bunches of P. W. Tullock, Coronation, Mrs. J. W. Jackson, Gabriel, Mr. Carter Page, Spotless Queen, and Mr. J. J. Crowe. Messrs. J. Burrell and Co., Cambridge, were third, staging Phineas, Hubert, Ianthe, Ida, and Albion in good form.

There were five contestants in the class for twelve bunches, distinct, of six blooms each, Mr. J. Walker being awarded the first prize with a refined stand. His varieties were W. P. Tullock, Mrs. E. Mawley, Viscountess Sherbrook, Lottie Dean, J. Weir Fyfe, Lord Roberts, Aunt Chloe, Mr. Carter Page, Lord Alfriston, Mr. J. J. Crowe, Galliard, and J. F. Hudson. Mr. C. Turner, Slough, made a good second. His best bunches were J. W. Wilkinson, Floradora, Lyric, Galliard, Lord Roberts, and Lyric; Mr. S. Mortimer bringing up the rear.

Class 8 was for forty-eight blooms, distinct, arranged on the orthodox boards. Again there were only three competitors, Messrs. J. Stredwick and Son being placed first for an exhibit rich in novelties. The varieties were H. J. Jones, Raymond Parks, Mabel, Mrs. Winstanley, Uncle Tom, Hercules, Red Rover, Mayor Tuppeney, Comet, Tasmania, Etna, Bruce, Green's White, P. J. Jackson, Eva, Sportsman, Rosine, Clara, Mabel Tullock, Elegant, Miss F. M. Stredwick, Marjory, Gabriel, Galliard, Ella Smith, Robin Hood, Mrs. Balding, Erin, J. W. Wilkinson, H. F. Robertson, Viscountess Sherbrooke, W. F. Balding, Ellen, Friar Tuck, Ringdove, Boadicea, Miss Brooker, Chas. Druery, Eric, Antler, Attraction, Nero, Princess, William Peters, Ajax, Aunt Chloe, and Lyric. Messrs. J. Burrell and Co. were a good second with fine blooms of Phineas, Decima, Dulcis, J. W. Wilkinson, Olive, Ibis, Colorado, Hector, Oliver Twist, Enchantress, Alicia, Albion, Ajax, and Lyric. Messrs. Keynes, Williams and Co. were third, having pretty blooms of Alpha, Ajax, Mrs. Carter Page, Cornucopia, The King, and Arab.

The class for twenty-four blooms, distinct, appeared more popular, for there were seven competitors who staged. Mr. W. Treseder came out first with a splendid exhibit. The varieties were Artus, Floradora, Lottie Dean, Britannia, Bernice, Alpha, Rosine, Clara G. Stredwick, Debonnair, Mrs. J. J. Crowe, Galliard, Vesta, Ajax, Mrs. A. F. Perkins, Lord Roberts,

Loyalty, Mrs. J. P. Clarke, Mrs. De Lucca, Prince of Yellows, Mrs. Carter Page, Uncle Tom, J. H. Jackson, Up-to-Date, and Mrs. Ed. Mawley. Mr. W. Baxter, Woking, was second, having nice even blooms of Mrs. McIntosh, Cornucopia, Floradora, Ethel, Mrs. J. J. Crowe, Mrs. H. A. Needs, and Monarch; and Mr. M. V. Seale third.

The decorative class for twelve varieties of six blooms, each arranged in vases with any suitable foliage, grasses or berries, proved an undoubted success, and formed a pleasing change, though there were only three exhibitors. The first prize being awarded to Mr. M. V. Seale, whose exhibit was tastefully arranged with a wide variety of foliage and berries. The varieties were Uncle Tom, Lord Roberts, Prince of Yellows, Galliard, Vesta, Starfish, Jealousy, Floradora, Britannia, Viscountess Sherbrooke, Mrs. J. J. Crowe, and J. H. Jackson. Messrs. Keynes, Williams and Co., Salisbury, were second with excellent flowers, though much weaker in foliage adornments, their chief varieties were Artus, Alpha, Cornucopia, Lord Roberts, and Mrs. J. J. Crowe; while Messrs. J. Cheal and Sons, Crawley, were third.

#### POMPON DAHLIAS.

The large class for Pompons, to be exhibited in twenty-four varieties, in bunches of ten blooms each, was poorly represented, only two exhibitors staging; the quality was, however, good in both classes. The first prize was awarded to Mr. C. Turner for blooms of the correct size. His varieties were Fosco, Thalia, Sunny Daybreak, Bacchus, Lilian, Mars, Vara, Adelaide, Daisy, Orpheus, Mephisto, Jessica, Minnie, Cyril, Phoebe, Douglas, Elsa, Darkest of All, Nerissa, Snowflake, Galatea, Buttercup, Little Bugler, and Emily Hopper. Mr. M. V. Seale, following with good examples of Adelaide, Doris, The Duke, Ernest Harper, and Edith Bryant.

Class 12 for twelve bunches of ten blooms, distinct, brought out a fair field of four entries, Messrs. J. Burrell and Co. being placed first with a sweetly pretty stand. The varieties were Nellie Broomhead, Bacchus, Violet, Emily Hopper, Distinction, Nerissa, Daisy Donovan, Mary Kirk, Ganymede, Little Bugler, and Jessica. Messrs. J. Cray and Sons, Frome, were second with an even display, some of the best bunches were Douglas, E. Harper, Sunny Daybreak, Nerissa, and Bacchus. Mr. J. Walker was third.

#### SINGLE DAHLIAS.

As usual, the entries in the single Dahlia classes were very poor; in the premier class for twenty-four bunches, there were only two entries. Messrs. J. Cheal and Sons, Crawley, being placed first, with a fine display, the colours being bright, and the whole exhibit fresh. The varieties were Tommy Duchess of Marlborough, Veronica, Columbine, Sunningdale White, Donna Casilda, May Sharpe, Miss Girdlestone, Aurora, Princess Beatrice, W. Parrott, Beauty's Eye, Naomi Tighe, Girlie, Formosa, Alice Seale, Meta, Nellie Nicholson, Hilda, Cicely, Miss Morland, Leslie Seale, Polly Eccles, and Victoria. Mr. M. V. Seale was a good second.

For twelve bunches there were again two competitors, Mr. J. Walker being first with blooms which were certainly on the large size of the correct type; the varieties were Formosa, The Bride, Elsie, Fascination, Beauty's Eye, Aurora, Duke of York, Naomi Tighe, Columbine, Robin Adair, Miss Roberts, and Leslie Seale. Messrs. J. Cray and Sons were second with good typical flowers of the correct size.

#### Amateurs.

##### SHOW OR FANCY DAHLIAS, INTERMIXED.

**TWENTY-FOUR BLOOMS, DISTINCT.**—Three sets were brought forward, but the quality was inferior compared with what one generally sees at this show. Mr. T. Hobbs, The Cedars, Downend, Bristol, led against Mr. T. Anstiss, Brill, Bucks, who was accorded the second prize. The blooms were generally under size, and lacked that lustre which a sunny or dry season produces. The choice blooms represented the varieties Mrs. Langtry, Richard Dean, a beautifully built bloom of dark magenta colour; R. T. Rawlings, the handsome yellow favourite, and the rich chestnut Dr. Keynes.

For the eighteen distinct varieties here, the premier award fell to Mr. S. Cooper, of Hamlet, Chippenham, with rather unevenly built blooms, amongst which the best were Victor, Arthur Rawlings, Sunset, and Mrs. Gladstone. The second award was poorly upheld by Mr. A. Parkes, Ightam Motts, Ivy Hatch, Sevenoaks, his blooms being small.

##### SHOW DAHLIAS ONLY.

A good dozen blooms were staged by Mr. H. Blundell, gardener to Mrs. St. Pierre Harris, Orpington, Kent, his stand including W. Powell, one of the largest blooms staged, but somewhat marked; Perfection, which is lighter than Dr. Keynes; Mrs. Glasscock, resembling R. Dean; F. Clifford, a new dark red of merit; Mrs. Gladstone, under size; Countess and Standard, with others. This was the only entry in the class. For the half dozen Shows, the winners were Messrs. Jeffries, Chippenham; A. Parks, of Sevenoaks; and Cousins from Chippenham.

## FANCY DAHLIAS ONLY.

Certainly these were far less attractive in our eyes than they have been in better growing seasons. Competition was not keen. For a dozen sorts the leader was Mr. S. Cooper, who had, indeed, the most superior set, staging good flowers of Mrs. Saunders, Peacock, Sunset, Lottie Eckford, and Salamander. Mr. Anstiss followed. Leading for the six was Mr. T. Hobbs; and second, Mr. A. Parkes; a third being captured by Mr. E. Jefferies.

## CACTUS DAHLIAS.

Though these, in respect of their beauty, scarcely compared with previous seasons, yet they furnished the chief attraction at the meeting. In class 21, for twelve varieties in bunches of six blooms each, we found Mr. L. McKenna, of The Honeys, Twyford, Berks, leading against two others; second and third awards going respectively to Mr. W. Peters, of Holmhurst Lodge, Baldstow, St. Leonard's-on-Sea, and Mr. F. W. Fellowes, The Lane House, King's Walden, Hitchin. In Mr. McKenna's stand were good samples of the showy Innovation, also Kathleen, and Mrs. E. Mawley. Mr. Peters staged True Friend (a dark blood red) admirably; with Florence, Major Tuppeney, which were beautiful flowers, and the rather washy-coloured Up-to-Date.

Four competitors faced the judges for the nine distinct, but Mr. P. W. Tullock, the well-known amateur from New Church Road, Hove, was incomparably first. His blooms were amongst the finest in the show, being large and wonderfully bright. He stages admirably, too. In the back row were Ajax, Galliard, and Lucifer; second row: Loyalty, Mrs. E. Mawley, and Florence; in the front: Mrs. Winstanley, Alpha, and P. W. Tullock, all of them of newer blood. The second place was filled by Mr. H. L. Brousson, Sidcup Place, Kent, having nice flowers of Rosine, Galliard and Lord Roberts, creamy white.

Class 23 for six, was alone supported by Mr. S. Cooper, and five contested in the next for the eighteen blooms. Here the merits of Mr. H. A. Needs' flowers were undoubtedly superior to those of Mr. J. Bryant, and staged on a jet-black board, they showed up well. Aunt Chloe was handsome, and Mrs. H. J. Jones was large and well coloured, though ragged compared with Gabriel, J. F. Hudson, and the bright yellow Eclipse. Mr. Bryant had strong blooms of Ajax, R. Dean, and Rosine, which was very deeply coloured. Third came Mr. Fellowes of Hitchin, but his flowers were small and otherwise below par. Three entrants in class 25, for twelve, showed bright blooms, Mr. McKenna here being foremost; Mr. H. Brown, North Street, Luton, next; and the Rev. S. Spencer Pearce, of Combe Cottage, near Woodstock, third. Out of half a dozen contestants for the six blooms, Mr. F. G. Oliver, of Tollington Park, N., was leader.

## POMPON DAHLIAS.

For twelve varieties, in class 27, there were five collections of these charming little flowers. Mr. H. Brown, Luton, was placed first, and staged the following:—Sunny Daybreak, Favourite, Jernea, Nerissa, Bacchus, Dr. Jim, Clarissa, Hypatia, Emily Hoffer, Lorna Doone, and Rosebud. The second place was filled by Mr. W. C. Pagram, The Whin, Weybridge, having Nellie Broomhead, Eva, G. Brinkman, and Phœbe as his most effective bunches; third, Mr. Peters. Mr. Brown again led, with Mr. S. Cooper second for the six bunches.

## SINGLE DAHLIAS.

Here Mr. J. F. Hudson, M.A., of Acton, W., staged the best six bunches of ten flowers each, including Donna Casilda, Naomi Tighe, Columbine, Aurora, Tommy, and Leslie Seale—a very bright coloured collection. The Rev. S. Spencer Pearce made a good second, having well staged samples of Miss Moreland, Cleopatra, Bride, and Victoria. Third, Mr. C. Osman, of Sutton. Mr. E. Mawley, in the next class, had large flowers of great substance and good in colour, and was first. His Demon was very rich and dark; Rosebank Cardinal is bright crimson, and Coronation is a shade brighter still. Beauty's Eye was also grandly shown. This was the sole entry.

## DECORATIVE CLASSES.

These were pleasing on the whole, but exhibitors have something to learn in colour contrasts and harmonies before perfection is reached. Mr. Hudson's basket in class 31, which received no award, was, to our mind, exquisite, the Smilax, the Ferns, and berried Viburnums being very tasteful. The first prize went to Mr. R. Edwards, Beechy Lees, Sevenoaks, with an arrangement in yellow and buff. He also led for a vase of Dahlias, in class 32, with a pleasing salmon variety. We were much delighted with Mr. Mawley's vase containing rich crimson Cactus flowers and sprays of the purple Prunus Pissardi—a splendid vase for a room of mahogany furniture. It, too, received no award, and, therefore, we are unorthodox in noticing it!

Mr. Needs was placed in the forefront for three vases in class 33, and here he contrasted a creamy variety with purple foliage, and yellow foliage with purple flowers.

## Open Classes.

Seven shower bouquets furnished a somewhat imposing display, and proved how adaptable the Cactus Dahlias are for use in this way. Mr. W. Treseder, Cardiff, was first with a heavy yellow bouquet; Mr. F. W. Fellowes, Hitchin, with an up-to-date presentment of crimson, neatly finished off with long ribbons at the back.

## FANCY SINGLE DAHLIAS.

With Duchess of Marlborough, Columbia, Urban Youens, Alice Scale, Victoria, and Adonis, Mr. M. V. Scale, of Sevenoaks, beat Mr. J. F. Hudson, whose set of six bunches were very pleasing. The third fell to Rev. S. Spencer Pearce.

## SEEDLINGS.

The following varieties received certificates:—

*Dahlia Elsa* (Mr. C. Turner).—A Pompon of merit, white, good in petal, and of excellent form. (First-class Certificate.)

*Dahlia Euna* (Messrs. J. Stredwick & Son).—A Cactus variety of average size and true petals; colour rosy lilac with yellow at the base of the petals. A very distinct form. (First-class Certificate.)

*Dahlia Eva* (Messrs. J. Stredwick & Son).—A Cactus variety, pure white, slightly green at the base of petals; petals long and slightly incurving. A good form. (First-class Certificate.)

*Dahlia F. A. Wellesley* (H. Shoesmith).—A Cactus variety already described in these pages. One of the best. (First-class Certificate.)

*Dahlia Henry Clark* (Messrs. Keynes, Williams & Co.).—A Show variety of considerable merit; cream ground, edged purple, with occasional splashes of yellow in the florets. (First-class Certificate.)

*Dahlia H. J. Jones* (Messrs. J. Stredwick & Son).—A true Cactus variety, the florets being long and slightly incurving; the outer petals are pink, shading to pale yellow in the centre of the flower. A good exhibition form. (First-class Certificate.)

*Dahlia Ianthe* (J. Burrell & Co.).—A Cactus variety, with long, narrow petals, yellow ground overlaid with rosy purple; will make a good exhibition variety. (First-class Certificate.)

*Dahlia Mabel Needs* (S. Mortimer).—A large Cactus variety with true florets, red, slightly shaded purple; stem appears weakly. (First-class Certificate.)

*Dahlia Snowdrop* (Messrs. J. Cheal & Sons).—A single white, with a yellow disc; a good form. (First-class Certificate.)

*Dahlia Vesuvius* (Messrs. J. Stredwick & Son).—A distinct break in the Cactus section; the florets are long and straight, while the colour is best described as yellow striped red. (First-class Certificate.)

*Dahlia William F. Balding* (Messrs. J. Stredwick & Son).—A Cactus variety, deep amber florets, shading off to yellow in the centre; petals claw like. (First-class Certificate.)

*Dahlia Winsome* (Messrs. Hobbies, Ltd.).—A capital white Cactus variety. The petals are narrow and incurving; should make an acquisition. (First-class Certificate.)

## Non-competitive Exhibits.

Messrs. H. Cannell and Sons, Swanley, occupied a table running the entire length of the hall with an exhibit of Dahlias, chiefly of the Cactus section, all being arranged with ornamental foliage, grasses, and Gypsophila. The most noteworthy varieties were Exquisite, Standard Bearer, Mrs. Winstanley, Mrs. J. P. Clarke, Cornucopia, John Burn, Sandpiper, Mrs. A. F. Perkins, Mrs. Horace Wright, J. H. Jackson, R. J. Hamill, J. W. Wilkinson, J. Weir Fife, Gabriel, Alpha, and Imperator.

Messrs. Hobbies, Ltd., Dereham, made an exquisite display of Cactus Dahlias, arranged gracefully in a variety of green foliage. The exhibit was noteworthy as not being too crowded, every bloom being well displayed. The newer varieties of Cactus were well represented. The following varieties were most striking: Mr. Amos Perry, Honeysuckle, Columbia, Florene, Sailor Prince, Mrs. J. P. Clarke, Aunt Chloe, Lottie Dean, Artus, Gabriel, Alpha, Vesta, Mrs. Winstanley, Loogaler (what a name), and Fred Cobbold.

From Messrs. W. Cutbush and Son, Highgate, came a good collection, arranged in bamboo stands, the front of the exhibit being filled with the usual show boxes. The most prominent were Innovation, Countess of Lonsdale, Imperator, Cornucopia, Britannia, and Mrs. J. J. Crowe.

Messrs. Barr and Sons, Covent Garden, also contributed a display of Cactus, single, and Pompon varieties, all the modern varieties being represented.

Messrs. Jones and Sons, Shrewsbury, staged a collection of the various types, the Cactus varieties being especially prominent. The Show and Fancy varieties were also good.

## Bath, August 27th and 28th.

Favoured with unusually fine weather, the Floral Fête Committee were in high spirits on the opening day of their autumn show, and were justified by the large attendance of visitors. The show itself was of all round excellence, plants, cut flowers, fruit and vegetables, all being alike of good quality.

With eighteen plants, twelve foliage and six flowering.

Messrs. J. Cypher and Sons were, as usual, an easy first, their Palms, Crotons, Statice, Heaths, &c., being excellent. W. J. Mann, Esq., Trowbridge (H. Mathews, gardener), second; and J. B. Wood and Son third. Messrs. Cypher and Mathews won with six flowering specimens; and Messrs. E. S. Cole and Son, and G. Hallett, with foliage plants. Messrs. Cypher's group arranged on a space of 200ft was disposed in their well known style, Orchids in variety, the Butterfly *Oncidium* in particular being a prominent feature, and single-stemmed Crotons in good variety, were grouped and dotted in a pleasing manner. R. B. Cater, Esq., Bath, was a very creditable second, and E. S. Cole and Son third; artistic taste and good quality of plant being alike present. In the single specimens, and with a collection of Orchids, Messrs. Cypher also won, a grand *Croton Andreanus* in a 10in pot winning the prize for a specimen foliage plant. Mr. George Tucker's nine Fuchsias were finely grown and flowered, but some other exhibits were not up to the standard of former Bath shows. The last-named exhibitor was also successful with Zonal Pelargoniums, Ferns and Begonias.

Roses in twenty-four varieties staged by Messrs. Perkins, Coventry, were beautifully fresh, bright and heavy. Mr. J. Mattock, Oxford, and Messrs. Cooling, Bath, following. Mr. J. Mattock scored with twelve Teas and twelve varieties shown in vases; Messrs. W. T. Mattock, and Perkins and Sons being also successful. Beautiful Gladioli, thirty-six spikes and twelve spikes, were staged by the Messrs. J. and W. J. Mattock, Mr. G. Humphries and Mr. F. Hooper also taking prizes. Dahlias were not so good or so numerous as is customary, Messrs. J. Cray and Sons, Frome; W. Treseder, Cardiff; T. Hoskins; T. Carr, Esq., and G. Humphries being representative names among winners. Herbaceous flowers were really marvellous, both in wealth and variety, Bath growers excelling.

Floral table decorations proved a most attractive class, both alike among the public and competitors, and perhaps greater criticism is evoked from this phase of floral competition than any other connected with flower shows. Needless to say, there were several disappointed ones on this occasion, and the judgment of the censors gave rise to eloquence in their praise or otherwise from many voices. It is worthy of remark, that none of the Bath ladies figured among the prizewinners. Messrs. Cypher won with an epergne, and with buttonhole bouquets; and with an arrangement of one kind of flower in a vase, Mr. Mattock was the victor in a hard fight, his vase of Sunset Roses being very chaste.

Fruit at Bath is always an attractive portion of the show, and though in extent there was a lesser competition than usual, high quality was none the less a predominant element. Mr. Mitchell, gardener to J. V. Fleming, Esq., Romsey, was a good first for eight bunches of Grapes in four varieties, his Madresfield Court, White Muscats, Black Hamburgs, and Gros Marocs being very superior in colour, weight and finish. Mr. W. Marsh, Bath, was a very good second. A collection of eight dishes brought out a spirited entry of seven. In this, Mr. Mitchell won by the excellence of his Grapes, Madresfield and Alexandrian Muscats being extra good, as also were Sea Eagle Peaches and Pineapple Nectarines. Mr. Strugnell, gardener to Colonel Vivian, Rood Ashton, was second, Hamstead Park Melon, Sea Eagle Peaches, and Alicante Grapes being his better dishes. Mr. Hall, gardener to Lady Louisa Ashburton, was an excellent third; his Grapes and Melons being extra fine. The latter was first with White Muscats, good in bunch, colour and berry; and Mr. Mitchell staged wonderfully coloured Black Hamburgs in a class for that variety.

Four classes are provided for Melons, two of them by Messrs. Sutton, which brought together a quantity of variable fruit. Messrs. Wilkins, gardener to Lady T. Guest, of Henstridge; Strugnell, Somerville, and Mrs. Greaves were the most successful names. Mr. Strugnell won from Mr. Mitchell with Peaches, fine Sea Eagles in each case; and Mr. Hall was successful with Nectarines. Pears were numerous, also dessert and cooking Apples, but generally the fruits were below the average in size and colour. Filberts were good, as also were Plums, Cherries, and Tomatoes.

Honorary exhibits from Messrs. Blackmore and Langdon—Begonias and Carnations—were most attractive. Messrs. I. House and Son for hardy flowers and Sweet Peas were given certificates of merit, as also were Mr. Fowle, Teignmouth, for a group of Carnation *Devonia*. Messrs. Blackmore's Begonias were well deserving of a higher award of merit, the collection being both extensive in flower and variety, well displayed, and intensely interesting. Messrs. House's Sweet Peas, too, were fine in colour and variety.

To the secretaries, Messrs. Pearson and Jeffery, much praise is due for the business-like tact which is brought to bear upon their arduous duties. They are supported by an excellent committee and chairman (R. B. Cater, Esq.), the latter an expert in matters horticultural as in his other high official capacities. In short, there is an ideality in the officers, and not less so the show ground—the Sydney Gardens—which dispenses abundant tree shade, ample accommodation and natural seclusion.

## Bristol Gardeners'.

The usual meeting of this association was held at St. John's Rooms, on Thursday evening last, under the chairmanship of Mr. E. Binfield, The Gardens, Old Sneyd Park. The lecturer for the evening was Mr. H. Kitley, of Messrs. Garaway's Nurseries, Clifton, his subject being "Seed Testing and Saving," with which he dealt in a very able and practical way. He impressed on his audience the absolute necessity of obtaining the very purest seeds possible, which was of the utmost importance for successful gardening. The best methods for testing the germinating power of seeds Mr. Kitley fully explained, which was practised by all of our leading seedsmen, who were thus enabled to recommend their seeds with the utmost confidence. He also advised the

Conference Pear. (See page 218.)

gardener to test his seeds before sowing the general lot. Every well appointed garden, the lecturer remarked, should be fitted up with a suitable seed room, wherein to keep the surplus seeds till the time for sowing, which would keep them free from damp and insects, and thereby save many failures. Referring to seed saving, Mr. Kitley strongly advised saving only from the most perfect forms, and from those first maturing. He also gave a list of those which retain their vitality for any length of time, as also those of short duration. His paper was much appreciated by all present, and he was cordially thanked for his effort. Prizes were awarded as follows: The first, being given by Mr. Chas. Kemp, was won by Mr. A. Baker (gardener, Mr. Orchard); the second going to Mr. J. B. Brain (gardener, Mr. Atwell), for six bunches perennials. For twelve spring sown Onions of mammoth size, Mr. Young was awarded a Certificate of Merit, Mr. Garnish obtaining one for some very fine Asters, Messrs. Ambrose and Son being also awarded one for some excellent seedling Carnation blooms.

## THE BEE-KEEPER.

### Driven Bees.

Driving is merely a more humane method of taking honey from bees in skeps than the old barbarous custom of killing them by placing them over a brimstone pit. The application of the word "driving" in describing the method sounds very formidable, but the following axiom of the Rev. L. L. Langstroth's explains why they can be so easily forced to desert the stores they have gathered at such expense:—"When frightened by smoke or by drumming on their hives bees fill themselves with honey, and lose all disposition to sting unless they are hurt."

The operation is performed as follows:—On a fine warm evening, give a puff or two of smoke at the entrance of the skep, and after allowing a few minutes for the bees to load themselves with honey, invert the skep and remove it to a spot as far away from other bees as possible, and place an empty skep in its position to catch the flying bees which will return home. Now, above the inverted hive (which for ease in manipulating should be placed in a bucket at a comfortable height) place another empty skep and fasten the two together at the point furthest away, and fix them with their backs to the strongest light, the front edges being about 6in apart, in which position secure them by driving iron on each side. This liberates both hands, and the whole structure will be quite rigid. Now, with the open hand tap the sides of the bottom hive hard enough to cause the combs to vibrate, but not sufficiently hard to break them from their attachments.

The bees at first view these movements with perplexity, and finally dismay, then commences, what in bee-keeping phraseology is termed the subdued roar, and at a run the bees make for the dark interior of the empty skep. If the queen is required she may be found as she passes over the junction of the two skeps and captured. When conditions are favourable they may be driven in less than fifteen minutes. If the operation is prolonged, pouring a little warm syrup between the combs will facilitate matters. Immediately the bees are cleared from the combs they should be secured by covering the mouth of the hive with porous bagging, or cheese cloth, and if there are two or three weak lots they may be joined together after removing the surplus queens.

To prevent robbing, it is necessary when placing them in their new hive to throw them into the empty brood chamber, placing the frames in position afterwards. The quilt, feeder, and entrance may then be adjusted. It is scarcely necessary to point out that ready drawn out combs for this purpose are invaluable. Never attempt to unite driven bees to an established stock by running them in at the entrance. This will result in nothing but fighting, thousands being killed, besides which most of them die before winter.

To strengthen a weak colony the driven bees should be placed on the spare combs in another hive close to the old stock, and any time up to October, when they have developed a good brood nest, they may be united by first smoking both stocks and then alternating the bars of bees with those in the weak colony after deposing the oldest queen. Much more is achieved by this plan of uniting. The amount of brood in the driven stock will represent the additional strength given to the weak lot.—E. E., Sandbach.

### "Russia," a New Magazine.

The title conveys the scope of this magazine's work, and its brevity leaves room for the imagination's play. Four numbers have reached us, the first appearing on July 19, the others in each week since. "Russia" is an illustrated journal (12½in by 9½in), devoted to policy, industry, commerce, literature, and art in their relation to Russia. The articles are useful and interesting in their several departments, and are admirably illustrated. Russian notabilities, soldiers, poets, authors, clergymen, peasants, and views of architectural, sculptural, and rural features in Russia and its towns, are portrayed in its pages. Politics, literature, and industry receive considerable attention in these four numbers before us, and if the publishers can continue to send out weekly issues of it, the educative influence it exerts should, at all events, be greatly beneficial to the great country it represents. The journal is beautifully printed on stout art paper; the cover is suggestive of snowy regions.

### Hardy Fruit Garden.

**PREPARATIONS FOR GATHERING FRUIT.**—The varieties of Apples and Pears are numerous, and the periods when the fruits are matured sufficiently extend over several weeks, according as to whether the varieties are early, midseason or late. The importance of careful gathering at the right time is only equalled by the care and attention devoted to storing under conditions which shall gradually bring the fruits to a perfect state of ripeness. At this period attention may well be called to a number of small but important items.

**THE FRUIT ROOM.**—Where there is much fruit, the varieties being numerous, and the quality of the fruit generally good, the provision of a good room for the purpose of storing is a prime essential. A room 40ft to 50ft long, and 14ft wide, will provide plenty of space for a considerable quantity of fruit. Arrange tiers of shelves down each side, or adopt a more modern system of storing the fruit in trays specially made for the purpose. These receptacles can be stored one upon another in a limited space, and, being portable, are easily examined from time to time. Whether permanent shelving or trays are used, however, the general cleanliness of the fruit-room must be seen to. Every portion of the walls should be limewashed after thoroughly cleansing the woodwork. Make a careful search for holes or crevices in the walls or flooring, as rats and mice scenting the fruit will make every effort to reach it, and the damage they can do in a short time is deplorable. Every proper fruit room has the means of heating, this being necessary in frosty and occasionally in damp weather. Should there be any defects in the working of the apparatus this is the time to remedy them. Finally remove all offensive matter from the floor, so as to secure perfect sweetness. Leave the structure open until thoroughly dry.

**CONVENIENCES FOR GATHERING FRUIT.**—Fruit that is out of reach by persons standing on the ground must be gathered either from steps, ladders, or from the limbs of the trees. Steps of a good height are very convenient for the outermost branches, which can be reached from them. They should be made firm and safe before using them, alike for the safety of the gatherer, and to prevent injury to fruit. Ladders must be light and convenient, and in good repair, danger arising at critical moments from defective rungs. Iron hooks which can be suspended from the rungs of the ladder or convenient boughs of the trees are almost indispensable for hanging baskets upon. The baskets may be of various sizes. Those used for the actual gathering or placing in the fruit direct from the trees must not be too large, and ought to have something soft in the bottom for the fruit to lie upon to avoid bruising. The gardener's apron is an excellent receptacle for holding fruit as it is gathered from the trees. The lower edge may be drawn together and held by one hand, thus forming a pouch, while, of course, the upper part is secured round the waist of the wearer. In emptying the gathering basket the fruits should be handed out separately, and carefully placed in larger baskets for conveyance to the fruit room. If, however, the permanent storing trays are used, all that is necessary is to place the fruit in them at once, and move to the fruit room without further disturbance.

**WHEN TO GATHER FRUIT.**—The gathering of fruit all at one time from the trees is not to be recommended, except in such cases as Plums or Damsons, but usually these have had a preliminary overhauling in securing the first ripened fruits. The best test for knowing when Apples and Pears are ready for gathering is to raise the fruits to a horizontal position, when, if ready, they will readily detach themselves. Of course, the appearance of the fruit is some guide, and should be followed before handling the fruit too freely. Plums come freely from the spurs just before they are ripe, and this is the best time to gather them, placing in a cool fruit room for a few days. None but sound fruit should be thus kept. Fruit of all kinds must be gathered only when dry. Soft fruit will much deteriorate if gathered damp, and do so in a very short time. Apples will suffer the least, but it is better to wait for dry conditions.

**PLANTING STRAWBERRIES.**—Abundance of well-rooted plants ought now to be available where the runners have been allowed to remain, and the precaution has been taken of affording the needful thinning-out of the crowded growth, together with the uprooting of weeds from among them. In many cases special preparation of the ground will have been given in order to facilitate the rooting of the runners, hence only the most desirable plantlets have been selected for rooting, and the rest dispensed with. It is possible to lift now all suitable plants with abundance of roots and soil attached, and to plant them without their suffering from the removal. In introducing fresh plants or varie-

ties from other sources roots may be numerous, but there will be little soil adhering to them; therefore give a little extra attention in planting these. Spread out the roots on small mounds of soil, covering with fine material, and pressing firmly. A good watering in the first instance is generally necessary in order to settle the soil about the roots, giving further supplies as required until the plants are well established. Cut off all runners immediately they appear, which they probably will do on strong plants lifted and inserted forthwith from the garden.

### Fruit Forcing.

**VINES.—EARLY FORCED VINES IN POTS.**—For affording a supply of new ripe Grapes in late March, or early in and through April, these are in some respects better than planted out Vines, which, unless in inside borders and light, airy, well heated structures, are not always satisfactory. Besides, the strain upon very early forced Vines is so considerable that planted out ones soon give indications of enfeeblement when started several years consecutively, so that it is found better in practice to secure stout well matured canes in pots, and after cropping them throw the Vines away, new ones being provided annually to take their place. Those for starting in November will now have the wood brown and hard, the buds perfected, and the foliage sufficiently matured if not off, for the removal of the laterals and shortening the canes to from 6ft to 8ft, according to the vigour, trellis to be occupied and the position of the plump buds. Whilst the cuts are dry it is advisable to dress them with styptic, patent knotting, or best French polish to prevent bleeding. Keep the Vines rather dry at the roots, and in a cool airy house. Where the Vines have to be bought they are best seen about now, orders being placed so as to secure stout, well-ripened canes of the most suitable varieties, which we find are Black Hamburgs and Foster's Seedling.

**EARLIEST FORCED HOUSE.**—Where care has been taken to preserve the principal foliage by cleanly culture, and a judicious encouragement of the laterals after the fruit was cut to prevent premature ripening of the principal leaves, the early forced Vines will now be in a condition to have the laterals reduced, also the bearing shoots, which will tend to induce rest and admit of early final pruning. This may be performed on early forced Vines before the leaves are all down, as the wood being brown and hard, the leaves, or some of them, turning yellow, they will not bleed nor start the buds provided the house is kept dry, fully ventilated, and cold. The pruning will cause the Vines to go more quickly and thoroughly to rest, but it will have the opposite effect on unripe ones and where the atmospheric conditions favour growth. If the Vines are in good condition they will afford bunches quite large enough if pruned to a couple of buds from the base, but when they are weak from overcropping or a long course of forcing, the spur shoots may be left a little longer to secure larger bunches. When this method is adopted shoots should be taken from as near the base as possible as well as the bearing, and not be allowed to carry fruit, but be stopped at the sixth good leaf, the laterals to one and subsequently as produced. Such shoots are sure to form good buds, as the extra foliage tends to invigorate the Vines and support the fruit on the other shoot, which can be cut away when the fruit is removed in favour of that retained for fruiting the following season. This alternate system of fruiting necessitates the shoots being kept wide apart for development, and exposed to light and air. If the Vines are grown on the usual extension system, it will be necessary to cut to plump buds on firm ripe wood, being guided by the space at command, for there must not be overcrowding. It is important that the house be thoroughly cleansed. Any weakly Vines, or those in an unsatisfactory state, may be improved by removing the soil down to the roots and from amongst them, substituting fresh loam, with an admixture of one-sixth of old mortar rubbish, a tenth of "nuts" charcoal, a twentieth of wood ashes, and a fortieth of crushed half-inch bones, with a sprinkling of some approved fertiliser. Lift any roots available for the purpose, laying them out upon the fresh compost, and cover 3 or 4 inches deep. This is best done before the fall of the leaf. It is a mistake to allow Vines when at rest to become dust-dry at the root. Comparative dryness is desirable, yet great injury is done by allowing the border to become dried to the extent of cracking and severing the fibres. The outside border should have a covering of some kind to protect the roots from the heavy autumn rains, which reduce the temperature considerably. Glass lights are preferable, as they throw off heavy rains, whilst allowing the sun to penetrate the soil. Some persons, however, are obliged to do without such aids, being content to apply a covering of leaves and litter after cold weather sets in to prevent the soil freezing, which is an absolute necessity in early forcing.

**SUCCESSION HOUSES.**—Midseason Vines have the fruit ripe or ripening, and will need a free circulation of air, especially in the early part of fine days, as the night dews are heavy, and the condensation of moisture on the berries takes place rapidly indoors if the atmosphere rises considerably before air is admitted. A little air constantly is a good thing, but it must

be increased early on fine mornings and a free circulation allowed whenever the weather is favourable. Moderate air moisture is essential for the benefit of the foliage and the sound keeping of the berries, but a close stagnant atmosphere soon causes the Grapes to spot and decay. The laterals should be kept from interfering with the access of light and air to the principal leaves, otherwise a good spread of healthy foliage over black Grapes is one of the best safeguards against their losing colour. White Grapes also do not become brown so soon when not exposed to the direct rays of the sun as they do when the foliage is thin. Where the Grapes have been cut the laterals may be reduced, also the long bearing shoots cut back to two or three leaves above the pruning buds! This will facilitate cleansing the foliage of red spider and other pests, and assist in plumping the basal buds as well as the ripening of the wood by the increased amount of light.

**LATE GRAPES.**—Where the Vines were started in good time the Grapes are well advanced in ripening. Keep the laterals well thinned, and thereby admit as much air as possible to ensure the finishing of the crop, not by large reductions at a time, but by frequent pinchings. Maintain an artificial temperature of 70deg to 75deg, falling 5deg to 10deg during the night, increasing to 80deg, 85deg, or 90deg during the day, accompanied with a circulation of air constantly, and free under favourable atmospheric conditions. Where the Grapes are only beginning to colour, somewhat sharp firing will be necessary to finish them properly before the days are too short and cold to admit of free ventilation, it being possible to do more in the next four or six weeks' time than in twice the time later on. With the Grapes well advanced in colouring and ripening, the atmospheric moisture should be reduced; those only colouring should have a moderate amount of atmospheric moisture to assist their swelling, not neglecting to supply water to the roots, and if need be top-dressings of fertiliser of a substantial and not forcing nature as required.

**YOUNG VINES.**—Those that have made a strong growth and are late in ripening should be assisted with fire heat, continuing it until the wood is ripe, accompanied with free top and bottom ventilation. Discourage any further growth by the removal of the laterals as they appear, and withhold water from the roots, only the soil must not be allowed to become too dry, and if the roots have the run of outside borders, some spare lights placed over the border, so as to throw off the wet, will be very beneficial. If the autumn be dry the border is better exposed, but heavy rains are better thrown off when the wood does not ripen kindly.

### Meteorological Observations at Chiswick.

Very little rain has fallen during the week, while the weather has become brighter and warmer.

### Trade Catalogues Received.

Barr and Sons, King Street, Covent Garden, London, W.C.—*1, Daffodils; 2, Bulbs for Autumn Planting.*  
 R. H. Bath, Ltd., The Floral Farms, Wisbech.—*Bulbs, Roses, &c., for Autumn Planting.*  
 Geo. Bunyard and Co., Royal Nurseries, Maidstone.—*Fruit Trees.*  
 William Logan and Co., Seedsmen, Bulb Merchants, and Florists, High Road, Chiswick.—*Bulbs.*  
 Louis Paillet, Vallee de Chatenay, Chatenay (Seine), near Paris.—*Special Trade List of Pæonies, Roses, &c.*  
 Pinchurst Nurseries, Pinchurst, N.C., U.S.A.—*American Seeds.*  
 William Sydenham, Tamworth.—*1, Roses; 2, Violas and Rock Plants.*

\* \* All correspondence relating to editorial matters should be directed to "THE EDITOR," 12, Mitre Court Chambers, Fleet Street, London, E.C. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense.

PHOTOGRAPH RECEIVED (Weston-Super-Mare).—Received with thanks.

DISEASED LEAVES OF TUBEROUS-ROOTED BEGONIAS (Surrey).—The leaves are infested with rust mite (*Tarsonymus begoni*), which is one of the most pernicious pests, as it is very injurious by its biting of the tissues and mode of life of the young in their early stages, causing the leaves to have a rusted appearance, completely checking the growth and often causing the falling of the leaves. The best preventive and repressive treatment is to spray the plants, on the under side of the leaves particularly, as well as on the upper surface, with tobacco water, 1oz of the strongest shag tobacco being placed in a vessel and a quart of boiling water poured in it, then covering over closely allow to stand until cool, then strain and apply by means of a spray diffuser, the simple article used by hairdressers, and costing about 2s. 6d., being very suitable for the purpose, repeating at intervals of a few days.

DECAY IN WOOD OF PEACH TREES (Gardener).—The pieces of wood cut from Peach trees are affected by gummosis, or gumming, a disease assigned to various causes, some authorities referring to the fungus named *Coryneum Beyerickii*, and others to *Cladosporium epiphyllum*, and others, again, to *Gloeosporium fructigenum*. In your case it appears to arise from attack of the very common *Cladosporium epiphyllum*, a minute fungus. The disease is indicated by the appearance of tearlike drops of almost colourless gum oozing from the branches, and the part above and adjacent becomes brown and dead. Diseased branches should be removed to sound wood immediately below the dead or affected part, and the ground given a dressing of air-slaked lime, applying as much as to make the soil quite white all over, even a quarter of an inch thick. In the autumn the trees should be lifted carefully and replanted, and some lime rubbish added to the soil, say a sixth, making the soil very firm under, about and over the roots. The gummosis is aggravated by the excessive vigour of the trees, and you would do well to take out a trench now one-third the distance from the stem the branches cover of trellis, and cut off all roots there, the opening being made down to the drainage. This trench may remain open a fortnight or three weeks, and then be filled in, deferring lifting until the leaves commence falling.

INSECT TO NAME (Idem).—The insect is the Potato bug (*Lygus solani*), which is found on various plants, commonly on the Potato, and does some injury, though not usually material, by sucking the juices. It is, however, rather uncommon, though sometimes appearing in great numbers in late summer, especially in the South of England, and often, associated with the Hop bug (*Lygus humuli*), is found on Chrysanthemums.

GROS COLMAN GRAPES BACKWARD IN RIPENING (Ripener).—You cannot do better than admit a little air constantly, and maintain a gentle warmth in the hot-water pipes so as to promote a circulation of the air in the house and cause the moisture to be condensed on the glass instead of on the berries, increasing the ventilation early, especially on fine mornings. We do not advise forcing treatment, as this hinders rather than forwards the colouring process, and lack of this is the greatest defect, therefore we should give the Vines plenty of time, not keeping a higher temperature at night than 65deg, and if it fall to 60deg in the morning all the better, but from the early part of the morning gradually raise the temperature of the house to 70deg, and keep between that and 75deg from fire heat through the day and until late in the afternoon or early evening, then allow to gradually cool down. A temperature of 80deg, 85deg, or 90deg may be allowed through the day from sun heat, and a free circulation of air. Beyond these temperatures we do not consider it safe, for though the Grapes may be ripened, they will be almost worthless from appearing unripe through lack of colour. The top-dressings of Peruvian guano and sulphate of ammonia will not help the Grapes in colouring, but a mixture of three parts dissolved bones, dry and crumbling, and two parts double sulphate of potash and magnesia, known in the trade as refined kainit, mixed, and 4oz of the mixture applied per square yard, scratched or very lightly pointed in, is likely to help the Vines in the current, or certainly in the future crop.

NAMES OF PLANTS.—Correspondents whose queries are unanswered in the present issue are respectfully requested to consult the following number. (T. B.).—The blue flower is *Trachelium caeruleum*; see separate answers to your other queries. (J. Todd.).—1. the Winter Savory, *Satureia montana*; 2. *Spiraea japonica rubra*; 3. *Spiraea japonica* var.; 4. *Helenium autumnale pumila*. (Rev. W. W.).—Probably *Lactarius volemus*, but we are unable to say precisely. (T. J. R.).—1. *Juniperus communis fastigiata*; 2. *Thuia orientalis aurea*; 3. *Cupressus macrocarpa*; 4. *Thuia gigantea*; 5. *Retinospora obtusa aurea*; 6. *Cryptomeria japonica*. (H. E. A.).—*Eccremocarpus scaber*; glad to be of service if we can. (T. J. R.—Second lot: 1. *Sequoia sempervirens*; 2. *Olearia Haasti*; 3. *Abelia rupestris*; 4. *Ercilla (Bridgesia) spicata*; 5. *Retinospora plumosa aurea*; 6. *Biota*. (W. P.).—*Polygonum affine*. (T. L. M.).—1. *Ceanothus Gloire de Versailles*; 2. *Leycesteria formosa*; 3. *Delphinium Belladonna*. (J. F.).—1. *Lantana delicatissima*; 2. *Gleditsia sinensis*; 3. *Rhus Cotinus*. (G. C.).—*Selaginella*, names sent by letter.

## A Wet Harvest.

Many years ago—we dare not reckon how many, but it was in our early childhood—the clergyman of our parish introduced a startling innovation. We had just begun to hear of harvest festivals and thanksgiving services on the safe ingathering of the crops, but he went beyond this, and asked his people to join in a supplicatory service at early dawn on that Monday morning when the general harvest was to begin. We remember going down to the church before the sun was fairly up to ask for the blessing of fine weather, and as children we felt so grieved and disappointed because, ere the breakfast hour came, the rain poured down in torrents. We do not quite recall how soon the weather cleared, but that early morning service made more impression on our mind than many an ornate harvest festival since. A wet harvest, what does it quite mean? It affects so many of us, and all adversely. No, perhaps not all; a wet time is a dragging time, and men must be kept to finish the work somehow. If the harvest is early and wet, and the wet is accompanied by warmth, things get on with a “bonny mess,” as the men would say. With upstanding light crops the difficulties are not so great, but should the crops be storm broken, i.e., that is beaten down, twisted, distorted, the work is hard indeed. Some fields look as though giants had made them their playground, and where to begin to reap is a puzzle. The ground is damp and soft, the machine drives heavily, an immense demand is made on the strength of the horses, a still greater demand on the machine, and the greatest of all on the temper of the foreman. Instead of easy, straightforward cutting, the machine is constantly getting clogged up. Very bad bits have to be mown by hand, and in no part of the field is a neat, tidy job made. Crops like this will not allow of the proper working of the self-binder, and the children will have to be called into requisition as band-makers once again; let us hope some will be found for the job. We have always been in favour of tying up corn as it was cut, and stacking at once, but there are crops which this year will have to be treated differently. We saw a field of Barley the other day full of good Clover, so tall and big; quite overmastering the grain crop. What can be done in a case like this? The Barley straw not over-fit, the Clover strong, long, and sappy, and it seems useless to tie it up as it is cut. Days are taking off, night dews are heavy, the sun of late has shone with no power, and the farmer may scratch his head in dire perplexity. There is not only the worry with the superabundant Clover, but these constant rains discolour the Barley, and at discoloured Barley no self-respecting maltster will look. Where the crops are laid the ripening is so uneven, so irregular, as to suggest when the grain is seen in bulk two or more varieties. Laid crops invite the wood pigeon, and much damage is done by these voracious birds; they instinctively seem to know where to find the soft milky grain which their soul loveth. If the field be near the village, sparrows, too, will be much in evidence.

A wet harvest means a slow one, and so the end of the months comes and the work is not done, and the higher rate of wages must still be paid, or, if not quite that, concessions have to be made. Work has to be found during the wet days, and what to give them to do sometimes fairly beats master and foreman. In old days much time was put in in the barn, twisting straw rope for thatching. That now is obsolete, string of all sorts being good and cheap. The wet that hinders harvest work is very productive of weeds among Turnips and Mangolds.

All manure is led, and stackyards cannot be cleaned up for ever, and by this time all weak places in the fences will be made up. There is another phase of the question to consider. Corn not fully dry cannot be threshed, and we do not know from our own observation where the straw for thatching is to come from, and straw that has been much weathered loses some of its best qualities. And there

is another thing very much lacking among farmers till they can get a bit of Wheat on the market, and that is money; how scarce it is we dare not surmise. Harvest wages to be met and current expenses, and nothing much to turn into money. Then there is the anxiety as to future work. Those who are looking forward to the Potato harvest wonder when those tubers will be safely housed. There are stubbles to plough, but they cannot be ploughed till cleared, and no Wheat can be sown till the Potatoes are lifted. We can only hope and pray for a fine and long back-end.

There is another little matter which perhaps affects the ladies of the household most—we refer to the absence of “hen corn.” Ours has been done a long time, and still the fowls must be fed, and it is just at this season that farmers’ fowls, as a rule, suffer. There is a disinclination to buy, and the fowls go often with half rations, or indeed little more than they can pick up, and they face, or perhaps go through, the moulting season ill-prepared for the extra strain on the system. We are buying meal, and we find it pays; there are plenty of eggs, and the fowls look the picture of health. The new corn must come soon, we have always been promised a harvest, and the promise has not failed yet.

Fortunately, a wet harvest now is not so disastrous to bread consumers as formerly. Who among us can remember the soft, sticky bread that was made from sprouted corn? Bread that was warranted to give indigestion to the strongest, and which was absolutely unfit for the invalid or child. We have changed all that, and although we grumble at the wretched price now obtainable for our corn, we cannot but be thankful that we can produce good, sound, dry corn to grind for our daily bread. The present generation cannot at all enter into the difficulties that beset their elders in this matter; they have been so used to the best flour and no offals that they would take ill to the soft bread resultant on a wet harvest. There is always some contributing country where the sun has prevailed, and the Wheat is firm and dry. There will be much shifting of stacks, taking the hedge-side ones out into the middle of the close, turning bottoms up to the sun, and let us hope to the wind, that admirable medium for drying. There will not be much corn left this year to get over-ripe, the anxiety will be to cut as early as possible; there is no time to be lost. The harvest moon will come and go without having served its end, and the sun will go down all too soon. It makes such a difference an hour or more less of daylight at either end of the day. The heavy dews, that are as searching as rain, fall early and disappear with reluctance, and the evening shadows fall while yet the work is but half done. We were going to say a word in pity for the gleaners, but they appear an extinct race. Who could glean with flour at 1s. 3d. per stone? Here is one word of warning to those who have stooks on seeds. If they have to stand long, move the stooks.

## Work on the Home Farm.

We began the past week with a small deluge, but since then we have enjoyed five successive fine days with a good amount of sunshine. The crops are ripening rapidly, and the harvest has commenced in the neighbourhood, though there is nothing yet ready here. Oats and Barley, especially the latter, are inclined to die away too quickly, and there is a fear that good malting qualities may be scarce. Samples will be very uneven, for the laid portions of the crops are quite dead, and some of the standing comparative green. The appearance of more settled weather is giving farmers more confidence in their self-binders, and they will be generally used after all. Report says they are doing good work so far. The land is a little soft for them, but it will soon be hard enough if the weather holds. We should not care to string-bind some Barley we saw a day or two ago, with alsyke level with the cars. Alsyke is very useful for pasture, but it is dreadful to harvest except under very favourable conditions. We have always avoided it for that reason. In a dry summer it is all right, and its success during the late droughty seasons have stimulated its use amongst sheep farmers. The best way to deal with a crop full of tall alsyke or cowgrass would lead to considerable difference of opinion. Some would mow it or reap it, and leave the Barley to dry in swathe or sheaf, not tying it up until it is ready to stack. This would do if the weather were settled and there were no very heavy dews. We should prefer to mow or reap with a self-raker, and tie the Barley up by hand immediately. If it is well and carefully stooked it will dry as quickly in stook as it will on the ground, and the grain will not be so liable to staining. Heavy dews spoil the colour very much when the Barley is exposed to them.

## BARRS' GOLD MEDAL DAFFODILS

Have received Twelve Highest Awards, 1902, including **TWO GOLD MEDALS**  
Descriptive Catalogue of all the finest sorts in cultivation free.

## BARRS' GOLD MEDAL TULIPS

Have received **FIVE GOLD MEDALS** from the Royal National Tulip Society; **SILVER CUPS** at the Great Temple Flower Shows, 1900 and 1901, and **GOLD MEDAL** 1902.

Descriptive Catalogue of the finest kinds for pot culture and for forcing, and for beds and borders outdoors, free.

## BARRS' HYACINTHS.

**THE FINEST SELECTED BULBS** for the greenhouse, sitting room, or exhibition, and specially selected varieties for bedding.

Descriptive Catalogue Free.

## BARR & SONS,

11, 12, & 13, King Street, Covent Garden  
**LONDON.**

## STRAWBERRY PLANTS.

All the Leading Varieties from the open ground and in pots.

Priced Descriptive Circular Post Free.

**DICKSONS Nurseries CHESTER**

## RIVERS' FRUIT TREES, Roses, Vines, FIGS, ORANGES, AND Orchard-House Trees.

**A LARGE AND SELECT STOCK ALWAYS ON VIEW.**

Post Free, 3d.

**THOMAS RIVERS & SON,**  
SAWBRIDGEWORTH, HERTS.  
HARLOW STATION, G.E.R.

## CARNATIONS.

### THE POPULAR FLOWER.

The undernoted are two exceptionally fine new varieties, suitable either for pots or outside.

**SIR R. WALDIE-GRIFFITH.**—A striking novelty of a perfectly unique shade of colour, being a rich orange-scarlet, with a sheen of amber; Clove-scented. Several Certificates. Per dozen, 40/-.

**DUCHESS OF ROXBURGHE.**—Primrose ground, striped with a lovely shade of terra-cotta and heliotrope. Several Certificates. Per dozen, 18/-.

**MALMAISONS, and many other varieties.**

Full Descriptive Priced Catalogue Free on application.

**LAING & MATHER,** The King's Nurserymen,  
**KELSO, SCOTLAND.**

EXTENSIVE COLLECTIONS OF  
HYACINTHS, TULIPS,  
NARCISSI, LILIES,  
SNOWDROPS,  
CROCUSES,  
SCILLAS,  
&c.

**BULBS**

All best qualities and at most moderate rates.

Delivered Free by Rail or Parcel Post.

Descriptive Catalogue No. 565 post free on application.

**DICKSONS Bulb Growers CHESTER**

## BEGONIAS.

### GOLD MEDAL COLLECTION!

Four Gold Medals and Four First Prizes in 1901.

THE BEST COLLECTION. SEE OUR CATALOGUE.

**B. R. DAVIS & SONS,**  
Yeovil Nurseries, YEOVIL, SOMERSET.

**TARPAULIN.**—I have a great quantity of large pieces of Tarpaulin, some new, but all of the best Navy Canvas, purchased from Government, useful for covers for carts, waggons, and machinery, at 25/- per cwt.; lot suitable for covers for buildings, at 12/- per cwt.; cash returned if not approved of.—H. J. GASSON, Government Contractor, Rye.

**PURE WOOD CHARCOAL,** Specially Prepared for Horticultural use. Extract from the *Journal of Horticulture*: "Charcoal is invaluable as a manurial agent; each little piece is a pantry full of the good things of this life. There is no cultivated plant which is not benefited by having Charcoal applied to the soil in which it is rooted." Apply for Pamphlet and prices to the Manufacturers—**HIRST, BROOKE & HIRST, Ltd. Leeds.**

### Wanted—Inventors.

**P**ERHAPS in no other trade or profession are there such golden opportunities for the inventive genius as exist in the improvement of implements and apparatus for use in the garden. If we make but a cursory examination of the tools which a gardener uses in his work—such as the spade, the hoe, rake, and fork, and others too numerous to mention—we cannot fail to notice how primitive and old fashioned these are, most ungainly in these days of labour-saving devices, for the work which they have to perform.

While the hybridists have been making such vast strides forward by the raising and selecting of new varieties, and the improvement generally of existing kinds, it may be safely asserted we are not only up-to-date in this respect, but, compared with other branches of horticulture, even in advance of the times. The same may be said of the cultivator and his methods, which have, during the last decade, certainly undergone a change for the better; (this probably being brought about by the greater facilities enjoyed by young gardeners of the present day, through the medium of schools, books, and gardening papers, these giving him a distinct advantage over his predecessors, whose attempts at self-education will stand out for all time as marvels of patience and perseverance in the face of almost insurmountable difficulties, and a worthy example indeed to all succeeding generations of gardeners.

Yet, while we have advanced so far in these directions, the improvement of garden apparatus seems to have been entirely neglected; in fact, the mechanical part of horticulture is almost at a standstill, and the importance of improving the ordinary

**R**EADERS are requested to send notices of Gardening Appointments or Notes of Horticultural Interest, intimations of Meetings, Queries, and all Articles for Publication, officially to "**THE EDITOR,**" at **12, Mitre Court Chambers, Fleet Street, London, E.C.,** and to no other person and to no other address.

work-a-day implements for gardening purposes does not yet seem to have been realised by head gardeners and nurserymen. Gardeners as a body are very conservative, and they regard with suspicion any useful invention that is likely to alter the old order of things. However, in these days of keen competition and rigid economy any useful invention which will save time and unnecessary labour should be given a fair trial, and if found satisfactory it should be at once adopted.

I believe there are many gardeners and others who have an idea in their minds for the improvement of one thing or another; but perhaps owing to lack of mechanical knowledge they are unable to bring it to perfection. To such a one it would be surely advisable to consult an expert rather than lose such an opportunity of benefiting not only themselves, but all the community at large. Indeed, it is these crude ideas and chance suggestions which have been the origin of some of the most wonderful mechanical devices of modern times.

Perhaps it would not be out of place to suggest one or two things in use in the garden which would be all the better if some brilliant individual with brains would come along and exercise his talents with the worthy object in view of superseding these relics of bygone days. Now, there can be nothing more simple than the humble but necessary flower pot. Nothing, I am sure, could be invented which would suit the requirements of a plant better than those now in general use. It is, however, almost incredible that someone has not made one that would practically be unbreakable, although, at the same time, it would remain porous, and also inexpensive, so as to be within the reach of all. An invention of this description alone would have a very beneficial effect on the yearly garden bill, and consequently upon the gardener also.

The syringe, again, is a very important article to a gardener, and one which is generally getting out of order, as the unfortunate operator generally knows to his cost. While it is promising to see several important changes in these, they are, however, still far from perfect. Indeed, some of them are as unwieldy as the ones they were intended to supersede.

It is almost idle to mention individual objects which would pass through the hands of the inventive genius and yet come out scatheless. There is barely an implement which would pass through such an ordeal. What a chance for young men with brains! Why should we go plodding on, content with the hard work and low wages, when there is a fortune at our very feet only waiting to be picked up? Many men have a taste for experimenting, both scientifically and mechanically; here, then, is a totally unexplored area open to all comers, although gardeners perhaps stand the best chance, owing to their practical knowledge of the requirements of plant life. In the long winter evenings which will soon be with us, it would be well to ponder over these suggestions with a view to conduct some experiments, however small, having for their object the improvement of all gardening tools and apparatus.—H. MUNCEY.

## Town Trees.\*

The Horse Chestnut (*Æsculus hippocastanum*) has fared better this year than the Limes. Grand as is the leafage and beautiful as are the flowers, the trees (now early September) far from beautify their locations in smoky districts and building-heat-reflected situations, for some trees retain but a sere remnant of summer clothing. Even in country towns there is a strong objection to be placed against the common Horse Chestnut, that of its spiny capsules and large shining seeds on footpaths and roadways, involuntary penancing pedestrians in autumn, and whilst on the trees stone-throwing boys cannot resist the inducement of a "sling." The double flowered variety is not open to this drawback; but it also has parted with most of its leaves, therefore must be placed in the same category as the species, both very little better for not turning "seedy" and become leafless earlier than Limes. Neither aphides nor red spider can be saddled with the mischief, therefore I must put it on the thin texture of the leaves and their indifferent resistance of drought.

### The Chestnuts.

The red or scarlet-flowered Horse Chestnut (*Æ. rubicunda*) is in some cases leafless and in other instances fast parting with the foliage. This is very regrettable, as it produces very fine terminal racemes of flowers, and is a very distinct and beautiful tree, and does not attain so large a size as the common Horse Chestnut, usually not more than half, hence not calculated to outgrow the space.

Of the Smooth-leaved Horse Chestnut (*Æ. glabra*), with its greenish-yellow flowers and very smooth leaves larger than in the common species, the evidence is meagre, but what there be points to very little better adaptation for resisting the heat-reflected influence of town atmospheres. For country towns this and the scarlet are very fine in the early part of summer; but the leaves will not stay on the trees in droughty seasons without littering after August, and capsules dropping on footways are a source of inconvenience to pedestrians.

### The Elms.

Passing to the Elms as next least resistant of town reflected heat and drought, the field-loving or so-called English Elm (*Ulmus campestris*) has withstood the weather and its enemies—the frog, cuckoo or jumper fly (*Euacanthus interruptus*), and red spider (*Tetranychus telarius*)—better than the mountain loving Scots or Wych Elm (*U. montana*) for its leafage has been made whitish, especially near the midribs, and the leaves are falling in showers, the result of red spider work.

The Cornish Elm (*U. c. cornubiensis*), with its small, strongly veined, coriaceous leaves, bright brown, smooth, flexuous, and compact branches when young, but, unlike man, becoming erect with age, has battled bravely, and occupies comparatively little space on account of the narrow branches, spread in proportion to the tree's height. Similar remark applies to the Exeter Elm (*U. m. fastigiata*) and to the purple-leaved (*U. m. purpurea*), the red spider not liking the leafage of the latter variety so well as that of the green-leaved forms.

But of all Elms for vigour and keeping clean, not any approach the Chichester or Huntingdon form of the smooth-leaved Elm (*U. glabra vegeta*), the tree attaining a height of 30ft in ten years from the graft. The record of this and the preceding species or varieties of Elm apply to country towns; for in smoky districts the trees in their various degrees are in sore distress, some leafless and others with but scanty and sere foliage. In no sense, however, are Elms so defoliate as the Limes and Horse Chestnuts. The latter do not submit readily to pruning. Elms, on the other hand, though not as tractable as Limes, bear almost any amount of lopping, not only with impunity, but with advantage, as the young growths from their greater vigour are more resistant of the adverse influences of town atmosphere, and when the trees are becoming aged, there being no question of their doing this prematurely in smoky districts, pollarding gives the trees a new lease of life, and is the best of all preventives, or even cures, if taken in time, of the attacks of the Elm bark beetle (*Scolytus destructor*).

### Hornbeams.

Hornbeams find little favour in the eyes of the town planter, though not any trees better endure rough and windy situations and thrive in poor conditions of soil. It forms a good hedge plant and bears pruning well, hence submits to restriction and with benefit, always provided the pruning, with the object of securing a vigorous growth, be done in the winter time. Of all trees, this Hornbeam (*Carpinus betulus*) is the most liable to possess "witches' besoms," which render it very singular in the winter time, some having the "brooms" at the ends of branches, as is common also to Birch, and then very interesting to lovers of Nature. The Hornbeam fares badly in smoky towns, and even in open ones suffers from attacks of various insects, especially small caterpillars, which riddle the foliage. Even this may be an advantage, as affording food for the insectivorous birds, which are not the least desirable accompaniments of town sylvanry.

### The Birches.

Birch (*Betula alba*) is simply the "queen" of country towns as well as "of the woods." No other tree combines so much elegance and graceful beauty, and even in fall of leaf the tints of rich yellow, scarlet, or red are "pleasant to the eyes." The drought and reflected heat of confined spaces trouble the silver, white, or common Birch, and it has marked its dislike by shedding its leaves, which, littering in September, are neither pleasing nor safe. Of the varieties of common Birch, the white and purple leaved (*B. a. albo-purpurea*), with leaves rich purple and a metallic lustre above, pale beneath, branches sub-pendulous, is very effective. The weeping Birch (*B. a. pendula*) strangely, like the weeping Ash, bears town impurities better than the common Birch, while its leaves or shoots are more slender and smoother. Of the cut-leaved weeping Birch (*B. a. laciniata pendula*) Young's variety is the best, the leaves being deep green, and deeply cut (lacinated). Of relatively small trees not any are more lovely than the Birches.—G. A.  
(To be continued.)

\* A full notice and description of the genus *Tilia*, or Lime Trees, forming one of the articles of this series, was given on July 25, 1901, page 74.—ED.]

### **Dendrobium nobile album.**

On several occasions during last spring plants of this exquisitely beautiful small flowered Dendrobium were exhibited in the Drill Hall. The variety first received a First Class certificate on March 27, 1900, when shown by Mr. J. Davis, gardener to J. Gurney Fowler, Esq., treasurer of the Royal Horticultural Society, and whose residence is The Glebelands, South Woodford, S.E. Our illustration shows the form and size of the variety very exactly.

### **The Week's Cultural Notes.**

The present may be described as a halting time between the two seasons in Orchids. Most of the summer flowering sorts are gone, and the showiest of the autumn ones are not yet. Still there is plenty of interest in the houses and plenty to do. Repotting will be in full swing in the cool house, and re-arrangement

**Dendrobium nobile album.**

in the warm and intermediate sections. I am not an advocate of shifting Orchids about unnecessarily, and when the best place for a certain species is found I like to leave it there; but independent of all this, there are times when a move is necessary.

Cattleya Harrisoniae is going out of bloom, and may be kept a little on the dry side, but allowed sufficient moisture to prevent shrivelling. A light position close to the glass is needed by this pretty species now, and it does not require any great amount of heat. C. superba on the other hand is just coming in, and the plants like ample heat and moisture right up to the time when the blossoms commence to unfold, a drier atmosphere being then needed to conserve the latter. C. Gaskelliana is busily rooting, and if the plants are in need of it there is no reason why they should not be repotted.

One of the most singular Orchids I know as regards culture is Lælia lobata, or Boethiana, as it is sometimes called. Pot it regularly; treat it well in all respects of heat and moisture, and other cultural details, and as a result it will grow everlastingly, but as for a flower you will never see one. Starve it by letting it grow out over the sides of the pot or basket, bake it in the summer sun, and be not too particular about its winter treatment, and most likely you will be rewarded by its lovely flowers in plenty. And they are very beautiful in their rich rose and purple tints, refined and delicate, yet making a brave show.

Among the Dendrobiums there will be some plants and species to remove from the growing quarters every week. The earlier plants of D. nobile and D. Ainsworthi, D. crassinode, D. Wardianum, D. Bensoniae, and D. Pierardi are amongst those now ready, while the majority of the evergreen section have by now finished their growth for the season. As soon as the last leaf is complete, and the apex of the new stem can be seen, take them at once to drier quarters, as a secondary growth starting now breaks the proper cycle of annual growth and rest.—H. R. R.

## **Lilies of the World.\***

The height given to each Lily must be accepted as comparative. In some moist soils the Lilies may grow higher, while in dry soils they may not attain the height named. For example, established clumps of L. auratum, L. pardalinum, L. superbum, L. Canadense, L. testaceum, &c., in moist soils may reach a height of 8ft or more. And so on with all the other Lilies.

In the Municipal Gardens L. longiflorum eximium attains a height approaching 5ft. I have never seen it before so tall, except when grown under glass. I have seen L. speciosum grown under glass attain a height of 10ft. Out of doors in England its extreme height is seldom over 4ft. Everything depends on the quality of the soil and the surroundings. If Mr. Arderne takes to cultivating Lilies amongst his Rhododendrons the maximum height will be attained there, and an effect as a floral display exceeding that of his grand show of Rhododendrons. You all know how superb this is.

European Lilies (genus Lilium), of which there are upwards of forty, mostly wild species:—Davuricum erectum (colour, rich cerise-scarlet, shading to yellow), height 2½ft. Davuricum Incomparabile (colour, intense rich crimson, freely spotted), height 2ft. Davuricum Sappho (colour, scarlet, shading to orange, moderately spotted), height 2ft. Candidum (the snow-white Madonna Lily), height 4ft. Chalcedonicum (the Scarlet Turk's-cap Lily), height 3ft. Croceum (the cottager's Orange Lily), height 4ft. Martagon album (the White Turk's-cap Lily), height 4ft. Martagon dalmaticum (the rich dark purple Turk's-cap Lily of Dalmatia), height 5ft. Pomponium (the graceful Scarlet Turk's-cap Lily of the Maritime Alps), height 3ft. Testaceum (the noble apricot-coloured hybrid Lily), height 5ft.

I notice in "Thompson's Gardener's Assistant" (last edition) that Mr. Van Houtte, of Ghent, Belgium, gets the credit of having raised this valuable Lily. I do not know where the editor got his data from, and very much doubt its correctness. Mr. Max Leichtlin, of Baden-Baden, a former student of Mr. Van Houtte's, made a careful investigation as to the origin of this Lily, and after much research, found it came originally from the nursery of Mr. Matthews, of Berlin, Germany. When questioned, Mr. Matthews could give no account of how it came into his possession, but was aware it got into circulation from his nursery. That it is a hybrid has been proved by Lieutenant-Colonel Clark, F.R.H.S., having succeeded in producing it by crossing L. candidum with L. chalcedonicum. I am particular on this point, as some works mention it as a Japanese Lily, and others state it is the Chinese Lily. I may further state it is the only really good hybrid Lily raised up to this time, as far as is known.

Japanese Lilies (genus Lilium) of which there are upwards of fifty species, mostly wild species (nearly all Lilies are used in Japan as an article of food), and I may add from what I saw on the hills and in the woods of Japan, there are still varieties of Elegans not yet in culture:—Auratum (the golden-rayed, crimson spotted hill Lily) type, height 5ft. Auratum pictum (colour, white, beautifully spotted crimson, petals tipped red), height 5ft. Auratum platyphyllum (enormous white flowers, spotted crimson, height 7ft. Auratum rubro-vittatum (colour, pure white, with a broad crimson band down the centre of each petal), height 4ft. Auratum virginale (large pure white flowers, with a golden band down the centre of each petal), height 6ft.

In the early days of the trade with Japan the hills around Yokohama were covered with this species, only a few are now to be seen, so that collectors have to go further afield, as the type is found wild all over the southern island. It is not yet fully known what Lilies are wild in the northern island of Japan. Some of the varieties of L. auratum offered by name are selections from the type, but in the case of platyphyllum, rubro-vittatum, and virginale, these are said to be found apart from the type. My informant told me they grew on islands off the coast. The three latter are propagated around Tokio from scales, while the large quantities of the type exported are collected in their wild habitats, and grown on and fattened up for the market. The wild bulbs are sized and cultivated from one to three years before they are marketable. Whether this fattening up has anything to do with their short life in our gardens is a question of which I am very much inclined to doubt. My opinion is that the short life of the bulb arises from their surroundings, which in most gardens may be attributable to uncongenial soil and climate, and perhaps too shallow planting, which does not give the stalk-roots a fair chance, and the bulb-roots an opportunity to play their part in the economy of Nature, and being so very cheap most people prefer to buy them annually as they do Hyacinths.

I remember in early days that the gardeners were frequently blamed for the bulbs disappearing. I have myself lost thousands of this Lily when I made an attempt to class them into a few good, distinct varieties. I planted largely and made descriptions up to 1200, but finding each year my stock almost disappear,

\* A descriptive list of Lilies (genus Lilium) likely to succeed in the Cape Peninsula and South Africa generally, with historical notes, and, when necessary, special cultural directions. Read at the monthly meeting of the Sea Point Horticultural Society, November 29, 1901. By Peter Barr, V.M.H., London.

I saw my labour was fruitless, and called off. Since then I have discovered the reason, and through the large importations and the comparatively low price of the bulbs grown in Japan, it was time lost to raise stock in England. If Mr. Arderne or anyone growing Rhododendrons would plant some *L. auratum* amongst their Rhododendrons, I think they would establish them, and if successful, which I feel sure they would be, their reward would be plants 10ft high, with immense heads of bloom.

Mr. McIntosh, of Walton-on-Thames, England, had annually a glorious display of *L. auratum* ranging from 6ft to 12ft high. When in bloom it would be indeed a very dark night if anyone accustomed to the garden failed to find their way about by the aid of the great blocks of these white flowers. It is true he was always buying fresh bulbs, but this was to extend his culture. I never heard of him having to replace deaths. His garden was undulating, his soil was very light, and to keep his Rhododendrons in good condition he had hydrants all over his place, and made a free use of the water, an absolute necessity to keep his Rhododendrons in condition. The drainage being good, the Lilies enjoyed the waterings. The stems of these *auratum*s were usually 4in to 4½in in circumference, and so strong that they were able without stakes to carry their immense heads of flowers. On the west of Scotland I have known one case of bulb being planted, and in five years increasing into such a mass as to completely fill a bed. A photo of this *auratum* will be found in the "Gardeners' Chronicle" of 1899; I think the month of May.

*Elegans* (*Thunbergianum*). This family is very numerous. I have seen them on the hills of Japan growing with scarcely any soil, and the stalk not much longer than the flower (3in to 4in), and I have found them in the woods in rich vegetable soil, 3ft high; but the stem, always feeble, being drawn up by the shade of the leaves, the colours are lovely. I will name a very few of the many in commerce.

*Elegans Batemanæ* (colour, rich glowing apricot-red; late flowering), height 3ft. *Elegans Alice Wilson* (large lemon-coloured flowers), height 2ft. *Elegans Beauty* (large brilliant orange flowers, shaded red), height 2ft. *Elegans G. F. Wilson* (flowers, apricot colour, large and erect, spotted purple, with a central yellow streak on the petals; late bloomer), height 2ft.

*Elegans Prince of Orange* (colour, clear apricot orange, spotted black), height 1ft. *Elegans robustum* (colour, large orange-yellow, with bold heads of large handsome flowers, spotted crimson), height 2ft. *Elegans Sunset* (colour, a beautiful glowing golden-chamois; large, handsome, free flowering), height 2ft. *Elegans Van Houttei* (large rich blood-erimson flowers, blotched with gold and spotted black), height 1½ft. *Elegans Wallacei* (very distinct; flowers rich glowing apricot-orange; very handsome and late flowering), height 2½ft. *Hansonii* (the Japanese beautiful yellow Martagon Lily), height 3ft. *Japonicum odorum* (the long funnel-shaped large flower, opens chrome-yellow; outside streaked dark chocolate-brown), height 3ft. *Leichtlini* (flowers golden yellow, spotted crimson, and gracefully arranged on the stem), height 4ft. *Longiflorum eximium* (this I need not describe; it can be seen in the Municipal Gardens in great quantity), height 4ft to 5ft. *Longiflorum robustum* (this fine species is distinct from *eximium*, and would be a good addition, long pure white funnel-shaped flowers, reflexed at the mouth; the stem towards the base is coloured black), height 3ft. *Speciosum album Crown Princess* (very floriferous; handsome fine white flowers), height 3ft. *Speciosum punctatum* (flowers white with faint rose spots and yellow anthers), height 3ft. *Speciosum punctatum album* (large snowy white flowers with yellow anthers and broad light green foliage), height 3ft. *Speciosum purpureum* (large purple-rose coloured flowers, heavily spotted crimson-purple; robust grower), height 3ft to 5ft. *Speciosum roseum album*, variety *Kraetzeri* (beautiful, large, pure white flowers; in the claw of each petal is a pure green line), height 3ft. *Speciosum rubrum Melpomene* (rich dark crimson, handsome flowers, heavily spotted purple, with each petal margined clear white), height 3ft. *Speciosum rubrum multiflorum* (suffused and spotted rose on a white ground, profuse flowering), height 3ft.

The species of *speciosum* rank amongst the most useful and beautiful of the Lily family, and are widely spread throughout the English-speaking countries. I was greatly surprised at not finding it common in the gardens of the Cape Peninsula; it is of the easiest culture.

*Tigrinum Fortunei* (stem covered with a white down, and surmounted with numerous rich orange-scarlet, beautifully spotted flowers), height 4ft. *Tigrinum Fortunei* double (the flowers of this handsome plant are perfectly double, and a rich orange-scarlet colour spotted crimson-brown), height 4ft. *Tigrinum splendens* (stem almost black, surmounted by a large pyramid of bright fiery orange-scarlet flowers), height 4ft.

The *Tigrinums* are almost as universally cultivated as *L. candidum*, and greatly prized; when seen in established clumps the effect is grand. In the leaf axils there are bulblets, which if gathered when ripe and looked after soon grow into flowering bulbs. The Japanese Lilies are generally of great beauty and easy culture, and those I have enumerated are exceptionally so.

(To be continued.)

## Economy.

"His ability is unquestioned, but his extravagance was unwarrantable," was the verdict, verbatim, of a good master on a clever gardener at the parting of the ways—their ways—which often crossed, the crisis coming contemporaneously with a batch of bills. Both master and man, however, have long since settled all mundane accounts, and in raking up the ashes of a dead past, perish the thought of any personal inference being deduced by readers of to-day, old or young; but the latter, at least, may find the subject furnished by our text worthy of their consideration, for frugal and thrifty management of a garden is grateful to employers, commendable in gardeners, and to both a highly desirable thing. Bills, too, are still troublesome; masters still as ready to make rough calculations of returns against cost of production, and still as apt to omit important figures which make the "tot" as untrue as it is misleading; hence, assuming that a sufficiently true bill is here presented for a brief study of economy, the general expenses of garden maintenance may be taken under sectional heads, the first and probably most prominent being

### The Labour Bill.

Cheap labour, like other cheap things, is often dear and unsatisfactory. Local circumstances, however, so generally control the wages question as to neutralise any action or opinion of the gardener; hence, momentous as the matter of wages may be, it is more or less excised from discussion. Apart from the question of overtime, which if done without may be something off the bill, it may be said that any direct reduction, short of lessening the number of hands, which is often a pennywise policy and seldom expedient, is not practicable. That is so. With a permanent staff and fixed wages economy of labour practically resolves itself into the management of men. The annual expenditure may stand at a set figure, but good generalship will ensure the highest return for the outlay, and there economy comes in.

A life's experience with some study of one's fellow men and their methods leads to the inference that head gardeners are as diverse in their modes and manners of government, and as open to criticism, as were our generals in conducting the South African war with, in their own way, as many difficulties to encounter. What fine studies of character there are, too, amongst the labourers! There is the fussy man, and he is generally talkative to boot, so anxious to impress the overseeing eye with the quantity of work he is doing, with an immodest amount of faith in himself and the importance of his personality on the staff. A good man he is, doubtless, in his way—his own way—but he is not the man after a head gardener's own heart. There is the schemer, with one eye for his work, the other being reserved for the special duty of watching your goings and comings, and the way he has by some Marconi method of letting all hands know when business calls you to the city or elsewhere, seldom failing, although based on such slight evidence as any small change in the more permanent parts of one's apparel, is highly creditable to his powers of observation. He was never better exemplified than in old Tom H., garden painter, glazier, and general handyman, whose rubicund visage, reaching the climax of colour where nasally projected, a leading light he had followed all his days, eloquently corroborated the oft repeated assertion, "I loves a drop o' good beer." Like the renowned Major Bagstock, Tom was "cute," yet on one memorable occasion his cuteness signally failed him. It was a day when Tom, ostensibly painting the roof of the big range, was in reality peeping from the depths of a deep gutter which lay between the roof and a high sustaining wall, noting t' Gaffer drive off for T— Station, en route for London, 140 miles away. How it happened we bothyites never knew, but happen it did; in less than an hour t' Gaffer's head and shoulders loomed high over the ladder top, just after "a drop o' good beer" in the shape of a gallon jar had been hoisted aloft, and was being broached by old Tom, aided by two of the faithful (?). Sequel, the sack. Sub-sequel, prayers, promises, and threatenings, and back in a week. And so went on the watchful, dodgeful policy to the end of the chapter.

Needless to illustrate more of the types so often met with and so well known, amongst which is the plodder,

always at it, yet by some clever sleight of hand and foot contriving to spin one day's work over two. The man who tootles through the day "We won't go home till morning," but is the first to slip off at night. Thankful one is to say there is the honest, loyal labourer, good to see, to speak to, and to have; a man who looks you straight in the face, and whose daily labour seems one of pleasure instead of painful task. His moral influence in the garden is incalculable, and to the gardener—his master—he is a tower of strength.—QUIZ.

## Old-time Gardening.

(Continued from page 123.)

### Trade and its Effects.

Trading companies, e.g., the English Merchant Adventurers, and the Hanseatic League, or Steelyard Company, had been engaged for centuries in an import and export trade with England previous to the period under review, the end of the sixteenth century; but their operations did not extend beyond the Continent and its great trade emporiums, whence the products of the East were gathered, to be sparingly distributed in the ports of England and Scotland. Chancellor's discoveries in Russia about the middle of this century produced a great impulse in trade. That was further increased by others who followed, and who pushed farther afield into Persia and other countries of that marvellous East, the goal that all adventurers were endeavouring to reach, whether from the north-west, the north-east, or the southmost extremities of the two vast continents which stretch far into southern seas.

Capital was freely provided by noblemen, merchants, and others, and the reports submitted by agents prove that all alike were animated by a sincere desire to obtain useful knowledge, as well as to extend legitimate trade. Chancellor's first report descriptive of Muscovia, as in reports made by others, contains very fair notes on native vegetation, and the uses to which it was put by the inhabitants. Some items are perhaps just a little exaggerated, or incline to the marvellous, as in the report of Jenkinson, who tells of "Pineapple trees lying along within the ground, which by report have been there since Noe's flood."

A copy of instructions by Richard Hakluyt, cousin of the "Collector" of voyages, "to Arthur Pet and Ch. Jackman for the Discovery of the North-East Strait," is altogether interesting. They were to bring home, among other things, dried fruits of the countries visited, and "kernels of Peares and Apples and the stones of stone fruits, seeds of all strange herbs and flowers, for such seeds of fruits and herbs coming from another part of the world, and so far off, will delight the fansie of many for the strangeness, and for that the same may grow and continue the delight for long time." A lengthy list of "Things to be carried with you" includes "Prunes damaske, Dried Peares, Walnuts, Almonds, Smal Nuts, The Apple John that dureth two yere to make show of our fruits." They were also to endeavour to find a market for Saffron, "because this realme yeelds the best of the world." "Garden seeds as well of sweet strawing herbs and of flowers, as also of pot herbs and all sorts of roots," were to be carried with them for sale.

The company promoting these enterprises had been urged to secure a direct trade with Syria and other Eastern countries before the Dutch could step in, and as a result in 1581 a charter was applied for and granted to the Levant Company, by whom direct business relations were opened with Turkey. Hakluyt's instructions to the Factor of this concern at Constantinople in 1582 reiterates the desirability of importing examples of rare vegetation, and as an inducement he gives a list of fruits, &c., that had been introduced by various persons, "and now," he concludes, "within these last four years there have been brought into England from Vienna in Austria divers kinds of flowers called Tulipas, and these and others procured thither a little before from Constantinople." In 1585 the Morocco Company was instituted, and in 1588 the Guinea Company received its charter. Private merchants, too, opened agencies in suitable centres, and we discover not

a few instances of new plants being introduced through their efforts.

In the year last named an interesting account of Virginia as then known was written by Thomas Hariot, "servant to Sir W. Raleigh." Hariot was a man of more than average ability, and very painstaking, and the "Commodities of Virginia" contains not a little worthy of notice by the horticulturist. Maize, Tobacco, and the Potato excited most largely his interest, and the description of the latter, as it is the earliest on record, may be transcribed as an example of his method. Native designations, it may be explained, are used in all cases. "Openawk," he writes, "are a kinde of roots of round form, some of the bignesse of Walnuts, some far greater, which are found in moist and marish grounds growing many together one by another in ropes, as though they were fastened with a string. Being boiled or sodden they are very good meate."

The expedition of which Hariot was the naturalist left England in 1585 and returned in 1586. Whether samples of the Potato were brought back is doubtful, though it was already known on the Continent, and Clusius mentions having acquired the plant in 1588. Lane, the commander of the expedition, is said to have introduced Tobacco, but Hakluyt shows its seeds to have been imported from "West India" several years previously, and it had been cultivated in Spain for nearly forty years in advance of this time. It will be apparent that the wonderful activity displayed by the English during the latter half of the sixteenth century, alike in promoting discovery of regions hitherto unknown, and in taking means to extend their trading boundaries, must have had a marked effect on gardening.

Previous to, and even during this period, novelties in plants were procured at second hand from Continental sources, as was the case with Tulips, the introduction of which by Busbeguus and others caused the greatest excitement in almost every European country. Flowers, as flowers, were perhaps not very highly esteemed, and it is a curious fact that any plant not useful as a food or a medicine was always recommended in a somewhat apologetic manner. Some of the earliest Tulips were indeed lost because the recipient, deeming them to be edible, made his supper off a number, and planted others in his garden for future use. When, however, the Tulip in its great variety was seen in flower, along with Narcissus, Crown Imperials, and other plants from Constantinople, a new era dawned in the history of gardening. Roots of these rare plants could be procured only by favour, and sometimes at a great price, and Lobel gives the names of the chief cultivators in several countries, just as to-day certain horticulturists obtain more than a local fame for certain plants.

The introduction of so many exotics had, moreover, a marked effect on the calling of the gardener. Previously, when the number of subjects cultivated was confined to a not very large collection of plants, many of which were indigenous, or so long established as to be practically so, gardening was unquestionably a matter of rule of thumb. Now, however, a gardener had to think for himself; he had to discover methods of culture suited to novelties, causing him to break from the time-honoured practices of ages and to establish new systems for himself. There was, too, a general extension of gardens, and Stone mentions a high-handed act of Elizabeth's favourite, the Earl of Essex, who enlarged his garden at the expense of the chronicler's father and others, and actually moved Stowe's house back 20yds to procure more ground for his garden!

Gerarde's "Historie of Plants," more generally recognised as the "Herbal," appeared at this time. Unlike other Herbals that had previously appeared, it not only discussed the more legitimate points suitable to books of that nature, but it also treated of many plants quite novel to the great majority of garden lovers of that period, and gave slight historical notes of their introduction, and how they had been treated by the writer, however, not always with that success which authors like to record. For these and other reasons the book became a classic on gardening, not even the "Paradisus" of Parkinson, published thirty years later, seriously affecting its popularity. These remarks, it is hoped, will make a short study of Gerarde's great work more clear.—B.

#### Plants at Victoria Park.

For the filling of a very large span-roofed house in Victoria Park, London, E.C., Mr. J. W. Moorman, the superintendent there, raises some thousands of Chrysanthemums annually. His collection this year are in very good condition, the leafage being generally stout and plentiful, the wood and growths firm for the season, and buds are promising nicely. There are even batches of Mrs. Barkley, with buds already prominent; Edwin Molyneux, too, promises admirably, and its needs seem to be understood by the grower. Mrs. Carpenter, Loveliness, Mrs. J. C. Neville, Mme. Gabriel Debrie, and especially W. R. Church, are each very vigorous and stout. The buds on the latter are good. Florence Molyneux with Sir Herbert Kitchener and Mrs. R. Darby made a favourable show. Mrs. H. Weeks is very strong and heavily foliaged, standing but 2½ ft high. The brilliant flowered R. Hooper Pearson is 4½ ft high, grown as triple stemmed plants, and the buds are now developing as finely as could be desired. Dry sunny weather is required in order to perfect the unripened growth.

#### The N.C.S. and the Royal Aquarium.

Writing to "American Gardening," Mr. Richard Dean, secretary of the National Chrysanthemum Society here, says:—"The announced sale of the Royal Aquarium, Westminster, and its probable destruction as a preliminary to building structures for religious purposes will deprive London of the only building in its centre in which a large horticultural exhibition could be held. For twenty years past the National Chrysanthemum Society has held its annual exhibitions therein; a Dahlia show has been held in it for a long time past, and a Sweet Pea exhibition during the past two years. It is central, the position can be readily reached from all points, and there is abundance of space. It is a very serious matter for the National Chrysanthemum Society to be rendered homeless, because beyond the Crystal Palace at Sydenham, which is too far south, and the Alexandra Palace at Muswell Hill, which is too far north, there is no other place commodious enough for the inclusion of a N.S.C. exhibition. The sale has to be ratified by the shareholders of the Royal Aquarium, but that they will assent to the sale of the building there can be no doubt."

## Notes from Gardening Literature.

(Concluded from page 195.)

The heating of glass structures by hot water was agitating the experts of that day (1820-40), and in all the journals or magazines drawings were given of the various systems. To describe these would hardly come under the scope of this paper. One only might be made mention of, viz., heating by hot water troughs, and where dips had to be made syphons were used. Some doubts were expressed as to the effect of too much moisture by that system, but according to the accounts it was not so in practice.

The pruning of fruit trees also caused as much controversy and difference of opinion as it does at the present day. Grape growing had not attained the dimensions of the present day, and in a communication from Mr. James Acorn, gardener to the Earl of Surrey, Worksop Manor, March, 1826, he gives details as to how he is able to maintain a supply of Grapes all the year round. An experienced Grape grower also gives his views of Grape growing in "London's Gardeners' Magazine," in 1833. "The border in front of the vinery should be 30 ft to 40 ft wide (?) and should be formed of loamy soil, sharp sand, and at least a fourth part of well-rotted horse dung. The Vines may be planted on the outside of the front wall, but the stems should be taken through it below the level of the surface. When it is desired to swell the fruit to a large size, the border should be well watered every evening in the swelling season, and covered during the day with litter to prevent evaporation.

"In order to have very late crops of Grapes the house should be kept dry by giving air every fine day, and supplying no more

fire heat during winter than is barely sufficient to keep out frost. If the house is in the neighbourhood of much coal smoke, the laps between the panes should be puttied, and the putty such as will not crack, which is effected by putting 1 lb of white lead to every 10 lb of putty, and instead of using common linseed oil, which dries and cracks, use sweet oil."

As putty is mentioned, the following use for the old putty is worth noticing. A correspondent wrote:—"Two years ago I had a heap accidentally placed on a piece of turf, it was afterwards cleared off and burnt. Since that time the grass in that place has required to be mown thrice to once in other parts, and the grass is of a much better quality. I intend to apply some to plants in pots, as I think it contains nourishment for plants in the absence of watering."

There were scientific men in those days, and Joseph Hayward, of Weymouth, author of "The Science of Horticulture," gives a recipe to assist fruit trees to set their blossom. He says the Peach, Apricot, Plum, and Apple are well furnished with blossoms, and often fail in the setting and fall off. These failures he had proved to be the effect of unwholesome food, and he advised the following:—"Just as the blossom is beginning to expand, take a Potato fork and make holes, 18 in apart, as far as the roots extend, by pressing the fork in, and giving the soil a gentle heave. Then dissolve some nitre in water (1 oz to 3 gal of water), and fill the holes with the solution. No manure must be given, but if after stoning of the fruit the tree should be unequal to sustaining its crop, the following preparation may be given in the same manner as the nitre. To 1 gal of blood add 1 gal of water and 1 oz of potash; stir the mixture well, and let it stand for a week. Now pour off the solution, and mix 1 gal of this liquid with 4 gals of water, and give it to the trees as above." This discovery he considered of great value.

In the earlier part of these notes I mentioned that in visiting the various gardens in England and Scotland, the writers freely expressed their opinions as to the conditions of them. I will conclude my paper by two or three quotations showing their remarks.

Loudon speaks of Drumlanrig in the highest praise, but finds fault with the attempt to make a carriage drive up a steep acclivity in front of the house, and suggests that they should have commenced the road two or three miles to the right or left and made an easier ascent. Whether that was carried out I cannot say.

At Caprington Castle, he says: "We were sorry to find that the gardener had recently had his cow taken from him, and we saw the carpenters at work fitting up his cow-house as a fruit-room. What a reward for a faithful servant of twenty-five years' standing!"

"At Williamsfield we regretted to see the park spoiled by 'dotting.' But perhaps it is not yet too late, and if Mr. Cooper, the gardener, a most willing and excellent man, will send us a correct plan of the trees and other objects, as they now stand, we will return it to him gratis, with corrections." [Loudon, be it remembered, was a renowned landscape gardener, and doubtless acted in writing thus quite according to his spontaneous dictates, knowing right from wrong in the principles of his calling.—Ed.]

"At Dalscairth we were surprised to find some green painted iron bridges, an artificial ruin, and other things, belonging, as we thought, exclusively to the Cockney School."

Coming to England, a Mr. Saunders writes rather disparagingly of Trafalgar House (Earl Nelson's seat). He says: "I am persuaded that a few bold strokes from a masterly genius would go far to raise this place to no mean station among its compeers. The place was in tolerable keeping, considering the little assistance that was allowed to the gardener."

Loudon, writing of a tour through parts of Middlesex, Berkshire, Oxford, Wilts, Dorset, Hants, Sussex, and Kent, says: "With respect to gardens and country seats, we may say that, on the whole, we never saw them in a state of worse keeping. The more extensive the gardens the worse they are kept. We scarcely recollect above one or two noblemen's places highly kept. The noblest place in Britain, perhaps in Europe, Blenheim, is going rapidly to decay." In a footnote Loudon added: "Let not this view of decay of noblemen's gardens induce gardeners in want of places to despair. Every gardener who has seen much service knows that a situation under a rich tradesman, merchant, or small landed proprietor is productive of far more comfort to him than one under a nobleman, where so many intermediate persons come between him and his employer that he is at all times liable to misrepresentation, and to be discharged without even an opportunity of explanation. As far as we have observed, the pay given to their head gardeners by men who are themselves in business is as great as, in many instances greater, than that given by noblemen. As the country goes on improving the small places will greatly increase, and with them a taste for gardening and situations for first-rate gardeners."—J. B. S.

Carpet Bed in Grove Park, Weston-super-Mare.

### Carpet Bedding in Grove Park, Weston-super-Mare.

It is not so many years since carpet bedding was in great fashion, both in private and public gardens. Times and custom change, and this once forward style of planting has become almost a lost art. There is no doubt about the popularity maintained by its adoption in public parks and gardens, and it lends itself so well to loyal devices such as that called so universally forth in this Coronation year. Mr. T. B. Mills, the superintendent of the Grove Park gardens, Weston-super-Mare, has on many previous occasions given ocular proof of his skill as a carpet-bedder; but this year he has excelled himself both in style and character, as the illustration of one of his beds on this page shows. Though his glass accommodation is so limited, he contrives to provide some 15,000 plants, hardy and tender, for this phase of garden work. This large heart-shaped bed is in itself a triumph of forethought and execution, 6,000 plants, all varying in colour, being used in this alone. The design is most intricate, a crown, an unfurled Union Jack, a Rose, Shamrock, Thistle, and Laurel-leaf all being worked out in well defined lines, and in bold letters formed of *Alternanthera*, Edward VII. is given due prominence. In other beds, of which there are several, devices such as stars, Prince of Wales plumes, &c., are worked out. Then there are companion beds with "E. R." and "A. R., the beloved," underneath. These are of Apple shape outline. Though carpet bedding is given the most prominent place, the freer style of planting fills ribbon borders and other beds, and all are kept scrupulously neat and trim. The abundant tree growth which abounds in this secluded spot makes it a pleasant resort for the use of the thousands of visitors and residents of this much frequented watering-place, and it also affords a beautiful foil to the flowers so well planted and tended. The colours of the varied *Alternantheras* were wonderfully fine, despite the cold and sunless season, and these served so well to define the lines and characters of the whole design. Needless to say, Mr. Mills receives many encomiums on the high merit of his work from admiring visitors, and it is scarcely necessary to add these compliments are thoroughly and honestly deserved.

—W. S.

### Some Impressions from Fruit Land.

Slowly our Coronation summer is wearing itself away. From the beginning it has not been an ideal one, and gardeners, along with the rest of their fellows, have indulged in many little grumbles. We cannot complain of long weeks of drought and continual burning sunshine, for Old Sol has been very shy with us so far. Frosts, too, have checked the ripening of Tomatoes outdoors and ruined the prospects of outdoor Cucumbers. The vigour of full growth seems to have gone off in the garden, and that air of what I may venture to call untidiness, which generally prevails as autumn approaches, is daily becoming more apparent. The timetable tells the cyclist that he must not go out without his lamp if he intends a long evening ride, and as the twilight fades into gloom and the mist gathers up over the corn-fields, where standing shocks now take the place of a rippling sea of ears, there is a something in the air which tells plainly that the summer is nearing its end.

Writing from a county in which the fruit industry is of prime importance, and the fruit topic is one of general conversation, one may be forgiven for retrospectively a little at this season. Like the links in a chain, the various fruit crops come in and are dealt with one by one, and, in passing, the growers have to reckon with them individually in the profit and loss account before making the collective summing up when the season is finally brought to a close. You may take the fruit harvest of the year in the light of a stage, and over some important scenes the curtain has already fallen.

#### The Strawberry Fields

are no longer scenes of picking activity, for the harvest is over. The plantations present a bedraggled appearance, and there is little to remind you of the traffic of a few weeks ago except a few stray empty baskets and a litter of paper in the corner where the packing was done. The Strawberry retrospect is not a pleasant one, and from beginning to end there seemed to be nothing but disappointments. What a fair prospect it was at first when the early blooms shone forth and growers saw visions of fancy Coronation prices from the early fruits! But it was not to be. One

killing frost sent shattered hopes crumbling to the dust, and the daily papers had big headlines telling of the failure of the Strawberry crop. But it did not fail, as growers realised later on.

The later fruits developed into heavy crops, which all came in at once, and every Strawberry growing district seemed to do its utmost to glut the central markets. The end was accomplished, because the growers were powerless to avoid it, and here a second and greater disappointment presented itself. You cannot hold back ripe Strawberries to sell when the market is eased, and they had to go. Prices fell in consequence, and many a luckless grower found himself, after paying the expenses of picking, transit, and commission, without a cent for himself. It is easy enough to prate about the rich mine of profit offered in fruit culture, but these instances teach one that it is not all honey, and now the very mention of Strawberries brings a look of gloom to the faces of many Kentish growers.

#### Gooseberries.

The frost that spoiled the chances of early Strawberries was also responsible for a severe thinning of the Gooseberries. So severe, in fact, in places that I heard of some growers bemoaning the loss of hundreds of pounds; but what proved to be such a calamity to some turned out to be a blessing in disguise to many others. A portion of the crop fell, but there was plenty left, and Gooseberries have not sold better or steadier for years. They have cost a little more to pick, but the returns have more than recompensed for this, and Gooseberries, which of late years have been looked upon as a poor-paying crop, have saved their reputation. The frost which lessened the supply also eased the bushes of their burdens to some extent, with the result that the fruit grew out larger than would have been the case had the original quantity remained.

#### Black and Red Currants.

In discussing fruit crops in the South, failure must be written opposite Black Currants. This highly profitable fruit has had a bad time of it this year.

The dreaded budmite pursues its work of destruction and baffles all attempts at eradication, and then the frost upset the calculations of growers who were looking forward to something of a crop in spite of the above pest. Between the two evils Black Currants have been very scarce, and those growers who were fortunate enough to have any have had good reason to congratulate themselves. It is reported, by the way, that the new Black Currant, Boskoop Giant, is proof against budmite. Let it be hoped that such is the case, but the same was said of Champion when it first came out. Experience, however, has proved the contrary.

Speaking of Red Currants, these are not counted amongst the really important fruit crops, and in spite of early losses they have borne well. I was walking through a plantation the other day in which I observed a number of standard Currants growing round the outskirts. On the upper parts of the stems and on the heads of these were long bunches of the finest Currants I have ever seen, and this method commends itself to anyone who wishes to make the most of ground and produce fine crops of fruit.

#### Cherries.

The time has gone when pessimistic heads were shaken over the prospects of the all-important Cherry crop. There were good reasons for the head-shaking, for though the blooming time was promising, the same frost that had so much to do with settling the destiny of other fruit crops somewhat upset the calculations of the Cherry growers. But the story of the Cherry crop is far from being a dismal one. The fruits were thinned everywhere, and the trees in some orchards bore nothing, but when the auction sales were held, prior to the picking, record prices were made, and the fruit in some good orchards fetched double what it did last year when the trees were far more heavily laden. And in regard to Cherries the fruitmen are on good terms with the salesmen because the returns came back recording good prices, which have allowed for the extra cost of picking and then left a nice balance in favour of the growers.

In spite of the fact that the war is over and work is said to be somewhat scarce in the country, the labour question has been a serious one, and growers have had to employ a class of workers that they would prefer to see on the outside of the plantations if good native material had been

forthcoming. One can hardly understand the dearth of agricultural labour in Kent, for wages are fairly good, cottages are cheap, and apart from the menfolk, both women and children can earn continually from the time fruit picking begins till the Hop season is over. The bulk of the Cherry traffic is now over with the exception of the Morellos, which in most parts are only a thin crop this year, and will not take much disposing of.

#### Plums are Scarce.

Last year about this time the common topic was about the glut of Plums and the chances of disposing of them, but now the scarcity of this stone fruit is the theme. Here and there you see trees fairly well laden, and some of the early varieties, such as Early Rivers and others, have found their way into the market; but, as a rule, Plums and Damsons are a thin crop, and some growers are having to be contented with nothing. This is not surprising considering the way in which the trees have been burdened in the past few seasons, though one regrets these extremes and wishes that moderate crops were more the order of things. Though fruit is scarce, blight is plentiful, and to this scourge may be traced to some extent the lightness of crops. Insect pests seem to increase in spite of the many insecticides now on the market and the modern methods of applying them, but then this may be traced to the fact that for every grower who attempts to keep down the foes half a dozen do not, and eradication is impossible unless there be a combined operation.

#### A Heavy Nut Crop.

Never for many years have Kentish growers had such good reasons for congratulating themselves on the nut crop as this season. On the stony hillsides where Kent Cobs and Filberts are cultivated, the bushes are heavily laden, and some persons who have had experience enough to offer an opinion say that the nut crop will be a record one. In a measure they are gratified, but there is also the lurking fear that the plenty will mean low prices, and that the crop will not be so profitable as it would be if it were only half as heavy. Nuts do not grow free from pests, and the foliage in most plantations is honeycombed by the ravages of hungry maggots. Some growers make war against them by spreading tarred sheets under the trees and shaking the maggots on to them, but so long as they do not destroy the precious nuts the majority are content to let the marauders have their feed of foliage, irrespective of the damage done to the trees.

#### The Harvest of Apples.

As I write we are on the fringe of the Apple harvest. The early dessert varieties, such as Mr. Gladstone, Irish Peach, Quarrendens, and Juneatings are ripe, and trade is being done amongst the Keswicks, Suffields, and early culinary sorts. One can only describe the Kentish Apple crop as being "patchy." By this I do not mean to say that it is poor, for it leans rather in the other direction; but Apples are not plentiful everywhere. Here you may see orchards laden, there a moderate crop, and in another instance very few indeed, but when it comes to the settling up, I think Apples will come out fairly well.

There was a grand promise, and everyone spoke of heavy crops, but they were reckoning without the season and the aphids, and the codlin moth and other ills that Apple life is heir to. Pests have played their usual havoc, and what we call "windfalls," but what are really grub-bored specimens, are already plentiful under the trees. The codlin moth caterpillar is the bane of Apple growers, but it is not altogether a curse, because it does the necessary thinning that growers cannot find it in their hearts to do, and the fruits which remain grow finer in consequence. Generally speaking, I think there are enough late Apples to keep us going well into the winter, but storage, unfortunately, is a point which many growers do not consider much.

The great idea seems to be to get the Apples off the trees and into the market with as little delay as possible, presumably in order that the coast shall be clear when the time comes for the foreign imports to arrive. You see we are very considerate in the way we treat our competitors.

#### Pears are Scanty.

I am afraid Pears will not tell heavily on the profit side of the fruit account this year. "Williams" I hear, are not generally plentiful, and many of these are grown in Kent. Pitmaston Duchess is another popular market variety, and

there are many others of more or less account. Considering the area, however, and the attention paid to other fruits, Pears, particularly the high class varieties, do not figure so conspicuously in the country as one would naturally expect, though in some parts their value is appreciated.

But I am afraid my impressions have occupied too much space already, so they shall be closed here. In their make-up they are both retrospective and prospective, and on the completion of the fruit harvest let us hope that the successes will outweigh the failures and show a substantial balance on the profit side of market growers' ledgers.—G. H. H.

## A Nurseryman's Visit to Canada.

Mr. Joseph Cheal, of Crawley, has had a trip to the United States of America and Canada. Of his visit, a report appears in the "Sussex and Surrey Courier," from which we learn that he saw some of the larger American parks in New York City and Brooklyn; he also visited Philadelphia. At Madison, New Jersey, he found one of his late pupils in command of an extensive private garden there, and other English gardeners superintend numerous gardens throughout the States. "From Madison," he says, "I then went on by boat up the Hudson River as far as Albany, a most lovely sail over picturesque and historical country. Passing on by rail from there to the Falls, the journey was continued by steamer across Lake Ontario to Toronto. Here I stayed for a week, and after this several days were spent in going up to the backwoods to see a young man who went out to settle there about two years since. This was nearly 300 miles north of Toronto; part of the distance was covered by rail to Huntsville, then a series of lakes had to be traversed by small boats, with necks of land between, and the first night had to be spent at a little wooden hotel at the head of the Lake of Bays, a picturesque lake about twenty miles long, a perfect network of promontories, bays, and islands, every piece of land, and even rocks, being covered with Pines and trees. The journey was pursued in the morning for several miles by lumber waggon through a forest which had recently been swept by fire, the dead and decaying trees presenting a most weird appearance, the last four miles being accomplished on foot, following a track through the primeval forest until a log hut was reached at one end of Oxtongue Lake. The settler was at home and kindly rowed me in his little boat to the other end of the lake to the hut and clearing of my friend. Here I had a little experience of real backwoods life, and a rough and lonely life it must be. This is a most lovely spot, but I formed a very poor opinion of the land for cultivation. There are millions of acres of rich prairie land yet unappropriated, but I should look upon this district as only a sporting country. Deer of different kinds abound in the forest, as also wolves and bears, and the lakes are full of fish. I succeeded in taking some interesting photos of the district.

"Afterwards I returned to Toronto, and several days were spent in visiting the principal fruit districts of Ontario. This is a strip of land about a mile wide and extending for over twenty miles round the shores of the lake, backed up and sheltered by a high cliff behind. I was surprised to see the thousands of acres of flourishing orchards and vineyards of this district, Peaches growing in the same way as our Apple orchards, and Grapes trained on wires, and these orchards are most carefully cultivated and kept remarkably clear from weeds and blights. A Government inspector of fruit accompanied me through these farms, and from him I gained much information. I then passed on to Ottawa, a beautiful and flourishing city. An introduction to Professor Robertson, the Commissioner for Agriculture, led to an interesting conversation about their experimental work, and I spent a most profitable day with Dr. Saunders, the able director of the experimental farms and gardens of the Dominion. I was much interested in their different systems of packing, storing and freightage of fruit, and an introduction to one of the directors of the Canadian Pacific Railway, Sir Sanford Flemming, led to an interesting conversation with him in travelling together from Ottawa to Montreal. I gained from him much information as to the progress and prospects of the Dominion. He said that immigration has been larger this season than any year previously, and that from the States they had had an influx of 24,000, and that their company had sold one million acres of land this year, and on asking him how much they had left, he said another twenty-seven million acres. And now as they push their branch lines right and left of the trunk, purchasers are found for the land adjoining. On all hands there are evidences of prosperity and progress. I had thought the long, cold winters almost an insuperable barrier, but the Canadians assure me it is not so bad as we imagine, and that the snow on land and ice on the lakes and rivers open up roads for hauling which are impassable in summer, and though the frosts are, very severe, the

wood of the fruit trees is so well ripened that it escapes uninjured; and the air is so dry that it is not unpleasant to human beings. The return journey was made from Montreal by the Allan line, and the steam down the St. Lawrence past Quebec is a very pleasant one, and a bit exciting in shooting the Lachine rapids above Montreal. We could not take the northern route, as the straits were blocked with icebergs, and in passing out to the south of Newfoundland we saw floe ice breaking up on the rocky coast."

## Rambles in Switzerland.

(Concluded from page 216.)

One of the peculiarities of alpine districts is the inability of the human eye to appreciate the vastness of the elevations. I was at the foot of the Jungfrau, which rises to the height of 12,852ft, yet it certainly did not seem to me so much higher than Snowdon, which is only 3,567ft. One of the most striking evidences of great elevation is noted by Mr. Macmillan, who observes that on Mont St. Bernard, at an elevation of 8,000ft, "water boils at about 187deg Fahr., or 25deg sooner than the normal point; and in consequence of this it takes five hours to cook a piece of meat which would have taken only three hours to get ready down in the valleys." Though the total of the elevation is so difficult to appreciate, the steepness of their sides is not at all doubtful, especially to pedestrians. Yet on these slopes, which no Englishman could mow, hay is made; but as no vehicle could rest upon them, the hay is carried home in bundles, enclosed in nets on the backs of men and women. It is stored under cover, for, in this land of universal pasturage, such winter fodder is more valuable than the scanty grain crop. Pursuing any occupation under difficulties, invariably leads to assistant inventions which would never be suggested were the occupation untrammelled by obstacles. One instance I observed where watering was needed on a hill slope, and the crops were in drills. A narrow four-wheeled dray had to be employed for conveying the water. One large vessel for holding the water would have been unmanageable, so there were in the waggon three casks connected by leather pipes, and the water was delivered to the crop through a tap and hose attached to the end head of the last cask.

Wood is the universal fuel, and it is chiefly of the Beech, which usually clothes the base of each mountain, as the Abies excelsa, or Norway Spruce Fir, exclusively occupies its higher portions.

The cottage gardens are small, but well stocked with the vegetables most common in England. The only crop unusual with us, but almost universal in the Swiss gardens, is the White Beet. It also is peculiar to see large patches of Dandelion cultivated in corners of fields. It is used for salading.

Honey is a perennial occupant of the breakfast table, and is of excellent quality and flavour. The bee hives, all on the old pit-and-brimstone system, are ranged on a shelf against the side of the house, about 6ft from the ground. I saw none otherwise placed.

The employment of the dwarf Palms as room plants has often been recommended in your pages. In Switzerland and other parts of continental Europe no such recommendation is needed, for they are so employed very generally. Even on the table d'hôte of every respectable hotel they are common. The *Corypha australis* is the species usually employed.

I have now turned over the last page of my note-book, and its first line is inscribed "Lausanne—Vevay." Indifferent though they are, yet here are produced some of the best of the bad Swiss wines. Vevay is the vineyard district of the cantons. Here is "L'Abbaye de Vignerons," or Guild of Vine-cultivators; and its motto, "Pray and Labour," is an admonition applicable to all the affairs of life. This guild bestows medals and other marks of honour upon the most skilful Vine-cultivators. At intervals of about fifteen years, also, a public festival is held, in which the most successful of the vineyard keepers is crowned, and borne in a procession, accompanied by various characters associated with the history of the Vine—such as Bacchus, Noah, Silenus, Pomona, the spies who returned from Canaan bearing Grapes, and many others. On this occasion, too, the prettiest and most worthy maiden of the district is dowered and married to her accepted lover.—W. J.

# NOTES & NOTICES

## Good Price for Kentish Fruit.

On September 2 Kentish Plums made exceedingly good prices, the better sorts realising as much as 10s. per bushel compared with 6s., the average of former seasons. Apples also sold freely at from 5s. to 6s. per bushel, an advance of over 2s. It is many years since there has been so good a fruit season experienced in Kent.—(*"Morning Post."*)

## United Horticultural Benefit and Provident Society.

The monthly committee meeting of this society was held at the Caledonian Hotel, Adelphi Terrace, W.C., on Monday evening last. Mr. C. H. Curtis presided. Five new members were elected, making seventy this year to date. Four members were reported on the Sick Fund. The amount of sick pay for the month was £12 12s. This society will hold its annual dinner in the Venetian Chamber, at the Holborn Restaurant, on Tuesday, October 7 next, at 6.30 p.m. The chair will be taken by Arthur W. Sutton, Esq., F.L.S., V.M.H.

## Our Bulb Number.

The bulb number, of which particulars are published on one of the advertisement pages in the present number, will appear next week (September 18). The issue will contain over twenty illustrations, with special articles. These, we trust, will be read with interest, and stimulate, perhaps, a fuller appreciation than ever with regard to the beautiful vernal flowers from the various bulbous plants.

## Past and Present.

Some time ago I wrote on the bothy question in the Journal, and gave a description of the bothy at Park Place, Henley-on-Thames, and of the pastimes provided for the young men there. I am certain many readers will look at the heading of this article and wonder what it stands for, but to those men who have lived at Park Place it is familiar. Thursday, August 21, was the meeting of past and present gardeners at the above place, the charming residence of Mrs. Noble, who not only takes a great interest in her beautiful gardens but also in the men, who have served under Mr. G. Stanton, the highly respected and well-known gardener there. It is, indeed, a meeting that must bring joy to him, to welcome back for the day the many old faces that have worked under him. Some of these are now holding high positions in various parts of the United Kingdom. The day proved to be one of the best we have had for some time, and from early in the morning till late in the afternoon old Park Place men streamed in. Three large tents had been erected for the occasion, which were beautifully decorated with national coloured flags, not forgetting the tables, which were done with choice plants by Mr. T. Powell. At luncheon, Leonard Noble, Esq., president of the cricket and football club, proposed the health of His Majesty King Edward VII. Mr. Stanton spoke of the great pleasure it gave him to see so many of his old men sitting around, and of the kindness of Mrs. Noble and family in welcoming them so heartily. A cricket match was played between the past and present members, and was won by the "past" team by a narrow margin of seven runs—a very good performance considering that some of the players had not touched a bat since the previous year. The gardens and grounds were thrown open, and those who did not care to watch the cricket could stroll round, and no doubt many would have a chat about times now gone. Just before tea all the members were brought together to be photographed, in which Mrs. Noble and family were taken sitting in front of the group. At 8.30 p.m. a smoking concert was held in the large room adjoining the bothy, which is used for gardeners' meetings, &c. I think many other large employers might follow the example set by Mrs. Noble, but I am afraid few will do so. It was no wonder that the cheers for her rent the air, and the desire of everyone was: "May she be spared for years to come." Mr. J. Powell, the energetic foreman at Park Place, and hon. secretary for the cricket and football, is to be congratulated on the manner in which he had arranged the cricket proceedings.—J. BOTLEY.

## Register of Nurseries, &c.

Messrs. Protheroe and Morris's Register of nurseries, market gardens, farms, florists' seed businesses, and partnerships, to be let or sold, for September, 1902, has been issued. It can be had from the firm at 67 and 68, Cheapside, E.C.

## Appointment.

Mr. George Goodall, for some time foreman at Heslington Hall, York, has been appointed by Lord Deramore, to succeed the late Mr. James Hornby as head gardener. Mr. Hornby had been in the position thirty-two years, and died in harness on August 31, and was interred at the parish church, September 3.—H. J. C.

## Forestry and Fruit Growing in South Africa.

Recent reports from the Government forest nursery which has been laid out near Thaba Nchu, show that surprising progress has been made. Over 100,000 seedling trees, mainly Eucalyptus and Pine, are now ready for transplantation. Experiments have also been made in the cultivation of Oak trees, of which eight acres have been planted, and the Wattle area under cultivation is being continually extended. The construction of dams and water furrows is proceeding. It is intended to establish plantations generally, and wherever the Government acquires land a portion of it will be preserved for forestry.

## The Martin White Essay Prize.

It will be remembered that Martin White, Esq., of Balruddery, Dundee, offered substantial money prizes for an essay on the decorative uses of flowers and their preservation, through the Council of the Royal Caledonian Horticultural Society.

For this prize there were no fewer than sixteen competitors, several of the essays being of considerable merit, and some of them needlessly lengthy. Though little in them was new or original, the prize essays are said by the judges to contain many valuable hints useful to both gardeners and those who do their own decorations. The prizes were awarded as follows:—First prize "Captain Cuttle," James Ewing, gardener, Castle Menzies, Aberfeldy; second, "Confido," Miss Hamilton Boyd, 56, Palmerston Place, Edinburgh; third, "Nemo Solus Sapit," John Wright, Hopton Hall Gardens, Wirksworth, Derbyshire. Highly commended: "Endeavour to Please," H. F. Smale, The Gardens, Wortley Hall, Sheffield; "Experimenter," Herbert Cowley, East Lodge, St. Mary's Home, Wantage, Berks. Commended: "Courage," J. H. Cumming, The Gardens, Grantully Castle, Aberfeldy. "Knowledge is Power," William Boyd, The Gardens, Belleisle, Ayr; "Clematis," John Botley, The Gardens, Scarlet's Park, Twyford, Berks.

## Echoes from Hamilton, N.B.

A storm of unusual severity, for September, passed over this district on Wednesday. As the gale blew with remorseless vigour through the leafy boughs of garden and forest trees, carrying devastation in its course, the destructive storm of approximate date, twenty centuries ago, and which dealt so much havoc to the Roman fleet in the neighbourhood of Richborough Castle, somehow forced its existence on our memory—why, we are unable to offer any explanation unless because storms of like severity are by no means common at that particular date. If the occurrence were ten or more days later, the wonderment would not be so great, as then all look out for the traditionary effects of Sol's passage across "the line." Anyhow, the effects of Wednesday's storm have been disastrous to garden and farm produce, not only in the district but over a great part of the country. And the fact that the gale blew in the forenoon from the S.E. and in the afternoon from the West and S.W., made its effects felt more seriously. Peas, Cauliflowers, and such easily injured produce were, of course, by the determined tactics of the elements, on this occasion, literally blown out of the soil. The orchards of the Clyde valley, we are informed, have suffered very severely; in many cases the trees have been wholly denuded of their fruit. Forest trees have, on account of the weighty nature of their leafage, sustained greater injury than they would in winter. Consequently, drives and avenues in gentlemen's policies were littered with fallen branches, twigs, and leaves. Flower borders and beds will not again recover their former gaiety. It is still more serious to see the Wheat and corn fields lying twisted and rain beaten, prostrate on the ground. The following day (Thursday) accentuated the damage of Wednesday by an almost continuous down-pour of rain. The elements are not yet very settled in appearance.—D. C.

**Royal Horticultural Society.**

The next fruit and flower show of the Royal Horticultural Society will be held on Tuesday, September 23, in the Drill Hall, Buckingham Gate, Westminster, 1.5 p.m. A lecture on "Some Lesser Known Japanese Trees and Shrubs"—specimens of which will be exhibited—will be given by Mr. James H. Veitch, F.R.H.S., at three o'clock. At a general meeting of the Royal Horticultural Society, held on Tuesday, September 2, thirteen new Fellows were elected, making a total of 898 elected since the beginning of the present year.

**A Catalogue with Illustrations only.**

Messrs. Vilmorin-Andrieux and Co's "Album de Clichés" presents a host of stereotyped plates of plants, flowers, and vegetables, with quotations in French and English money values, beneath. The names of the subjects are supplied as well, but otherwise there is no text. As a trade guide, it must be very useful, but retail prices do not appear. Potatoes, Cabbages, Carrots, Oats, annual flowering plants, &c., are included in this, the second edition, supplement August 6, 1902. The firm's address is 4, Quai de la Mégisserie, Paris.

**The Gardens, Ragley Hall.**

On Thursday, September 4, by the kindness of The Marquis of Hertford, the beautiful gardens and pleasure grounds at Ragley Hall, were thrown open to the general public, and an opportunity was again given the visitors to contribute to the funds of The Gardeners' Royal Benevolent Institution. The inhabitants of Alcester and neighbourhood gladly availed themselves of the opportunity to inspect the thousands of bedding plants, specimen Coniferae, &c. Great interest was manifested in the pyramids of Plumbago, Zonal, and Ivy-leaved Pelargoniums, of 6ft in height. A novel and attractive feature of the carpet beds was that of the designs reminding one of this eventful Coronation year, crowns, coronets, and stars. Warm thanks were expressed for the kindness of the Marquis of Hertford in granting the privilege of a special day on behalf of the G.R.B.I. Thanks were also extended to Mr. R. D. Christie, the head gardener, for his efforts to further the pleasures of the visitors. A good amount was collected.

**Horticulture at University College, Reading.**

University College, Reading, was founded in June, 1892, at the instance of the House of Christ Church, Oxford. It was incorporated in 1896. By authority of decrees of the University of Oxford, a joint committee, consisting of representatives of the Oxford Delegacy for the extension of teaching, of the University College, Reading, and of the Royal Agricultural Society, supervises the horticultural instruction and examinations, and awards certificates. The college consists of departments of letters and science, agriculture and horticulture, music, and the fine arts, and provides teaching for about 1,000 day and evening students. In addition to lecture and class-rooms it contains zoological, botanical, chemical, physical, and bacteriological laboratories, art studios, students' library, and common rooms, and there is a garden for horticultural instruction. The college advises in the adjoining counties with regard to insect pests, plant diseases, the identification of plants, and the manuring of soils. With regard to the Department of Horticulture, the eleventh session (1902-1903) commences on Thursday, October 2. The horticultural course extends over forty weeks, which is ten weeks longer than the ordinary college session. The courses of study are arranged to meet the needs of those young men who are preparing for the Oxford and Reading Joint Committee's certificate in horticulture; the Royal Horticultural Society's examinations; or who intend to be instructors in horticulture to County Councils. Further, those who may desire (as the prospectus puts it) "to manage their own gardens," may here receive some necessary useful training. Practical instruction is given in the College garden, to the superintendence of which Mr. W. H. Patterson, an able gentleman of varied training, has lately been appointed. Mr. Patterson is also the lecturer in horticulture. The director of this department of the College is Frederick Keeble, M.A. (Caius College, Cambridge), who is the exponent of botany to the students. The subjects of the curriculum are: Horticulture, chemistry, botany, entomology, soils and manures, bacteriology, bee-keeping, book-keeping, and meteorology. Those who are desirous of further particulars should communicate with Mr. Francis H. Wright.

**Notes on Hollyhocks.**

Few of our garden flowers have undergone such vicissitudes of popularity as the Hollyhock. It is really not so very many years ago that there existed collections of choice varieties in many gardens of note throughout the country; while they were treated as florists' flowers by many admirers. Then came the dreaded disease (*Puccinia malvacearum*) that in a few years swept the great majority away, leaving only those with the most robust constitutions. At this period the stately Hollyhock was indeed under a cloud, and remained so for many years; in fact, Mr. Editor, it really has not yet recovered the popularity it once held in our estimation, and for this reason I am penning these notes, in the hope that I may persuade a few more people to take up their cultivation, or at least find room for a few of these stately plants in their gardens. They may do so without fear or trembling, for the Hollyhock of to-day is quite a different being, as it were, when compared with the weaklings of a few decades ago. The modern strain have good, vigorous constitutions, and escape, more or less, the attacks of the fungus. This desirable fact has been brought about within the last few years by a few specialists who have raised seedlings annually, and by cross fertilisation have achieved some remarkable results without destroying the vigour of the plants. So much so, that at the present day we have varieties and colours that are worthy of a place in every garden, whether on the flower borders, or in shrubberies, or in any other suitable position.

Personally, I am no advocate for named varieties, which have to be propagated by cuttings or division, it being a well-known fact that seedlings come pretty true to colour and character, and in such plants we get the health of the seedling. Good collections can now be obtained giving a wide range of colours, from pure satiny white to cream, pink, rose, red, reddish purple to almost black, the latter being a very deep maroon, so there is a good selection of colours to choose from. While mixed seedlings can be purchased more cheaply, and if obtained from a reliable source they are sure to be good.

I should now like to draw attention to the single forms that were always despised in the days of our fathers; but now that single flowers are so much in vogue we can admire the tall, stately form of a single flowered Hollyhock without being thought to be a "bit of a crank," and, after all, they are lighter in appearance than the double forms. During the past few years they have been very much in evidence in all our suburban districts, and with their varied colours they make a beautiful display, while their hardiness and adaptability to almost any soil make them general favourites wherever they are grown.

As to cultural details, they are simple in the extreme. If planted in good garden soil they will take care of themselves, for they are so hardy now that the old method of lifting them and wintering them in frames is no longer necessary. If grown without the aid of strong manures or fertilisers, one has little to fear from the fungus. If we desire to keep special colours, it can be accomplished by propagation from cuttings, or division of the stock after flowering. Those who are more ambitious, and desire to improve the already existing forms, can do so by carefully crossing them and raising the seedlings. The first cross will not give the result one requires, but if the seed is again sown from the first cross the desired results are often obtainable. This has been so several times to my knowledge. Reliable strains of seeds can now be obtained cheaply, and if sown in the spring will make fine plants for flowering the following year.—AN OLD CONTRIBUTOR.

**Summer Bedding: Plants and Arrangements.**

(Continued from page 219.)

Another of the sweetest beds in Hyde Park was that where a dark blue *Viola* had been used to carpet the bed, and flesh coloured Carnations were over this. There was no edging, but the contrast had a telling effect. A rectangular bed contained eighty-four evenly grown plants of *Fuchsia Marinka*, each profusely flowered. *Coreopsis tinctoria* and *Nierembergia gracilis* were used to impart further grace, the carpeting being of *Leucophyton Browni*, a grey, trailing, wiry stemmed plant. The edge was of oblique alternate bands of this, and *Alternanthera amabilis*, each

Bath Show: Side View of the Fruit Tent.

"band" being about 2ft in breadth. A simple yet pleasing arrangement was that of *Lilium speciosum* above, and crimson *Celosia pyramidalis* beneath, edged *Alternanthera versicolor*. In another bed the yellow *Celosias* were employed.

*Lantana Drap d'Or* (golden) over blue *Violas* was good. In a round bed were *Lantana delicatissima* over white *Violas*. Crimson *Celosias* were also used, with an edging of *Alternanthera amoena*. The large beds of foliage plants need not be noticed at this time, they having had due reference in past seasons. The above notes complete the review of Hyde Park bedding, but at

#### Ravenscourt Park,

near Chiswick, Mr. Gingell, the superintendent, has also one or two charming arrangements. Such simple beds as those with crimson *Celosia pyramidalis* over *Antennaria tomentosa*, or yellow *Celosias* over *J. B. Riding Viola*, are sweet. A larger bed with bays and angles is entirely filled with *Abutilon Thompsoni*, each a specimen plant, staked, and with large foliage. *Coleus Verschaffelti* and *Koeniga maritima* (outermost), is also very handsome. *Grevillea robusta* over a bed of *Begonia semperflorens* edged with *Euonymus radicans variegata* is noteworthy.

Rather too dull, but novel, is a bed of *Cyperus alternifolius* with blue *Lobelia* beneath, and edged with a golden leaved *Fuchsia*. White *Antirrhinum* below a dark red *Fuchsia*, edged with *Funkia ovata marginata*, commends itself at once. There is much to admire, too, in two small round beds near one of the gates. These are filled with *Begonia semperflorens rosea* and blue *Lobelia* mixed, edged by *Sedum tabulaforme*. Throughout the park there are many beautiful foliage and flowering shrubs, and I know that Mr. Gingell has chosen these with a view to having a continuance of bloom the whole season through. The keeping of Ravenscourt Park is in very capable hands.

#### Hampton Court.

The bedding here is exceedingly beautiful, and executed with care, forethought, knowledge, and good taste. The keeping of the gardens in general is entirely satisfactory. Perhaps in point of merit these notes of the bedding here ought to have been given a prior place, but I am recording my impressions in the order of my visits. Mr. J. A. Gardiner is the superintendent of this historic garden.

I need not attempt to describe the beds, but only name the subjects used in the most effective arrangements as follows:—Mixed *Verbenas*, mostly of crimson colour, with *Abutilon Thompsoni*, and edged with a white variegated Ivy-leaved *Pelargonium*. Carmine flowered *semperflorens Begonias* with white *Koeniga* and Golden Feather *Pyrethrum* intermixed, having erect *Plumbago capensis* (4ft) above, and edged with *G. F. Pyrethrum*. Another had *Fuchsia Scarcity* (red) with *Abutilon Savitzi* mixed, and both 3½ft to 4ft in height. Beneath was *Chlorophytum variegatum* and *Bouvardia corymbosa Humboldtii*, splendidly flowered and choice. The edge was of *Leucophytum Browni* and

small plants of *Pelargonium H. Hieover*. A charming bed—*Leucophytum Browni* (grey) over the surface; *Begonia La Fayette* (crimson) above this; *Arundo Lindleyana* (like "Gardeners' Garters") lending grace, dotted over the bed, and an edge of *Abutilon vexillarium variegatum*, sometimes called *A. megapotanicum*.

Rich and bright in colour was a round bed of tuberous *Begonias* in named varieties, mostly carmine and crimson flowered. Laing's Rosy Red is a very good sort. *Abutilon Savitzi* was used above, and the edge was of white *Lobelia*. Most telling, too, was the contrast of *Koeniga* (tufted little plants) below and between *Begonia weltoniensis*, grace being imparted by *Eulalia gracillima*, and an edge of variegated Ivy-leaved *Pelargonium*. Again, take *Begonia ascotensis* in conjunction with *Centaurea candidissima*, and having a carpeting of *Mesembryanthemum cordifolium variegatum* undermost. Decidedly attractive was *Pelargonium Crystal Palace Gem* (golden foliage) and starred over it the flowers of a *Viola Bluebell*, standard plants of *A. Thompsoni* harmonising with the *Pelargonium*. The edge was *Lady Plymouth Pelargonium*.

With *Pelargonium Crystal Palace Gem* as an edging, and *P. Flower of Spring* in the centre, *Viola J. B. Riding* peeping up all over among the foliage, and standards of *A. Thompsoni*, another charming bed was presented.

In a round bed were noted *Fuchsia Mrs. Marshall* (or one like it), with *Begonia weltoniensis* under, with *Viola Countess of Kintore*, the edge being *Euonymus radicans variegata*. Mixed crimson flowered tuberous *Begonias* over yellow *Musk*, and having half-standard *A. Thompsoni* with them, was bright and attractive. Crimson *Celosias* contrast grandly with the *Musk*. Quite one of the finest was a mixed *Begonia* bed (*La Fayette*, *weltoniensis*, *ascotensis* and crimson tuberous) with dwarf *Centaurea candidissima*, and *Pyrethrum Golden Feather* intermixed. *Arundo Lindleyana* was used above, and the edge was of *Mesembryanthemum*, banked outermost with *Echeverias*. The bed was oblong, 18ft by 12ft. Very simple, and yet very fine, was a bed of *Bouvardia corymbosa Humboldtii* (white) with *Viola J. B. Riding* (violet-purple) beneath. *Antirrhinum Pride of the Morning* (white), mixed, though not crowded, with *Henry Jacoby Pelargonium*, and having an edge of *P. Harry Hieover*, was good.

One of the larger beds contained *Agapanthus umbellatus* mixed with *Campanula pyramidalis* (the blue and the white), and *Marguerite*, undermost, edged also with *Pelargonium Little Trot* (like *Lady Plymouth*), and was handsome. Another fine combination included *Mrs. Pollock Pelargonium* and *Viola J. B. Riding* filling the centre; *Lobelia splendens* shooting up above, with fine plants of *Fuchsia Sunray*, and an edging of *Veronica Andersoni variegata*.

The foregoing notes include references to the best efforts and effects in the general bedding, but the larger sub-tropical beds are not particularly inspiring. One large oblong bed contained a great variety of plants, including *Musas*, *Cordyline indivisa*, *Cannas*, *Latania borbonica*, *Phormium tenax*, *Abutilons* in variety, *Ficus elastica*, 8ft high; *Melanthus major*, or Honey

Mr. Cave's Gros Maroc Grape.

Flower (7ft), *Cuphea platycentra*, *Ricinus communis*, and *R. Gibsoni*; *Eucalyptus globulus*, *Dasyllirion Hookeri*, *Acacia lophantha* (10ft), *Fatsia japonica*, and other plants, having *Tradescantia zebrina* and *Euonymus radicans* over the ground. In Hyde Park we find Palms, *Eucalyptus*, *Cordylines*, *Phyllostachys*, and such similar plants in larger beds, with *Cannas* and *Funkias* beneath and as edgings. As a rule some *Bougainvilleas*, *Plumbagos*, *Acalyphas*, and plants named in my list on page 202, August 28, are employed in other beds, or are plunged deeply in the grass throughout the region of the beds.

#### Regent's Park.

Mr. Jordan maintains the floral decorative features of this park ever at the highest, and has developed the naturalising of plants in the grassy recesses and by the shrubby banks. In the springtime the park is crowded with brilliant *Crocuses*, *Daffodils*, and other flowers of the season; now it is *Hollyhocks*, single and double, and *Pentstemons*, *Snappedragons*, *Violas*, and hosts of other gay and handsome subjects. In the formal flower beds and borders are some charming displays. In an oval bed we find yellow *Carnations* over *Viola Blue Diamond*. A great bed of mixed *Fuchsias* in all sizes is quite a feature, and the plants are well flowered. The large sub-tropical bed near that containing succulents is again rich and at its best, but it is unnecessary to name the plants. One of the brightest small beds contain *Abutilon Savitzi* and golden *Celosias* over *Tradescantia zebrina*. There are also dwarf plants of red-leaved *Acalypha musaica* and *Chlorophytum variegatum*. Borders of crimson and golden *Celosia pyramidalis* intermixed, and having *Saxifraga muscoides* and white *Lobelia* over the ground beneath, is also very pleasing. A bed of *Araucaria excelsa* (5ft) with bushy *Marguerites* below them, in a round bed, gave charm, because it was novel. A narrow border having *Dactylis glomerata variegata* and bushy plants of *Begonia semperflorens* mixed with *Grevillea robusta* above, and *Saxifraga muscoides* as a broad edge, might be copied with advantage elsewhere. *Abutilon Thompsoni* and *Begonia Corbeille de Feu*, both as tall plants, the bed being edged with *Salvia Scalaria* (small, and grey leaved), and *Cineraria maritima*, deserves notice; and lastly there is a pretty little bed filled with white tuberous *Begonias* above blue *Lobelia*.

#### Victoria Park.

Bedding in this very large and interesting place in the East End of London is so furnished as to produce a brilliant display of flowers rather than refined foliar effects. A round bed with purple leaved *Celosia pyramidalis* above the yellow flowered *Musk*, and edged with *Alternanthera paraonychioides*, was neat and bright. The great scroll carpet bed each year conveys a supplicatory sentence of loyal tenour for King and country. The excerpt this year prays that "God and his angels guard our sacred throne," and beneath, or in front of this, "God Save the King." The words are easily read, for the large letters, formed neatly of *Echeverias*, stand out boldly from their setting of

Mr. J. V. Fleming's Eight Dishes of Fruit.

*Herniaria* and *Alternanthera*. The large bed of succulents provides another feature of interest, the more so this year because of two green-leaved *Agave americana* now flowering. The scapes reach 25ft or so in height. The yellow flowers seem to furnish special attractions and reward to the bees. Around the bed of succulents there are plunged *Agapanthus* and *Araucarias*. The colour and effects from the following were good:—An oblong bed with *Pelargonium Raspail* in the centre and a broad band of blue *Ageratum* surrounding it, the edge being of golden *Fuchsia*, probably *Meteor*. A three-winged geometrical bed had also scarlet *Pelargoniums* filling the centre, then a band of *Flower of Spring*, or similar variety, with the flowers of a purple *Viola* peeping through the leafage, and succeeded by another band of the dark leaved *Coleus*, outside of which came blue *Lobelia*, and lastly an edge of *Echeveria*. A round bed of dark leaved *Cannas*, edged with *Iresine* and *Echeveria metallica*, gave a study in dark red; while a similar shaped bed contained *Zea Mays variegata* with a dark crimson flowered *Antirrhinum* through and among the foregoing. In Victoria Park there is a deer enclosure with a colony of these beautiful sportive creatures grazing contentedly. Peacocks and peahens are about to be installed, and with their winter garden, a *Chrysanthemum* house, botanical garden, and spaces for cricket, football, and other recreations, their ground for lectures, mass meetings, bands, their bathing and boating lakes, and splendid roads for cycling on, all within the area of this park, the public within reachable distance of it have no cause to grumble at the variety of features furnished for their use and enjoyment.—J. H. D.

Black Hamburgh Grapes.

### Fruit at Bath Show.

Bath horticultural exhibition was held on August 27 and 28, and a report of the show appeared in last week's *Journal* on pages 229 and 230. To-day we illustrate some of the fruit exhibits, including a side view of the fruit tent, from photographs taken specially by Mr. E. E. Rye of Bristol. The collection of eight dishes of fruit on this page won first prize. This was staged by J. V. Fleming, Esq. (gardener, Mr. W. Mitchell) of Romsey, and included the following: *Madresfield Court* and *Museat of Alexandria Grapes*, *Pineapple Neectarines*, *Sea Eagle Peaches*, *Quarrenden Apples*, *Williams' Bon Chrétien Pears*, *Angelina Burdett Plums*, and *Triumph Melon*, an excellent collection.

The *Gros Maroe Grapes* were those staged in the class for any variety of black Grapes, by R. C. B. Cave, Esq. (gardener, Mr. C. Smith), and finer bunches are seldom, if ever, seen at any show. The *Black Hamburgh Grapes* on page 246 were products of Mr. Mitchell's skill, he who succeeded with the above collection of eight dishes of fruit. The fruit at Bath Show is uniformly of a superior quality. In a succeeding issue we will show Colonel Vivian's *Peaches* as grown by Mr. Strugnell; and a specimen *Fuchsia* from Mr. G. Tucker of Hibberton Marsh.

## Gadding and Gathering.

"HERE AWA', THERE AWA'."

### A Cricket Match of Interest.

For the first time since the Fruit and Vegetable and Floral Committees of the Royal Horticultural Society came into being, they met yesterday week to spend one afternoon together at the sport of cricket. The event was of marked success, for not only were there a goodly company of the fruit and floral leaders present, but each was there with the purpose to enjoy the game, and to contribute to the pleasure in it of the others. The day was as nearly perfect as possible.

Leopold de Rothschild, Esq., had placed his beautiful pitch at Gunnersbury Park for use by the visitors on this occasion, and the renowned gardens were open, too, these being inspected probably by everyone at the meeting. The cricket field itself is unequalled on its own merits or surroundings by any other west of Lord's or the Oval. The Fruit Committee batted first, and proved in the end that they possessed the more expert batsmen. Mr. G. Woodward was captain, while of the Floral Team, Mr. Howe, of Chrysanthemum fame, stood as leader. Both captains quitted themselves ably, the former having noteworthy support from E. Beckett, R. Parker, George Reynolds, and W. Iggulden, while the efforts of Messrs. W. Howe, J. Hudson, and C. R. Fielder, were the most helpful in augmenting the florists' score. As one witty member remarked, the "floor all" committee did not on this occasion justify its name, and several succeeded in "bagging their brace." In both innings the Fruit Committee attained the mastery, notwithstanding all manners of styles in bowling from 'dribblers' by Mr. Jones to the sky-high flights from Mr. Fielder. Even Mr. Richard Dean renewed his youth, and probably his thoughts flew back to fifty, or even sixty years ago, for he would be a youth of thirteen even with sixty years deducted. We heard—and may we not tell it?—of his having risen at three o'clock on the morning of the match to complete some literary work and be free to join his contemporaries during the day.

Mr. Bates proved an adept at "blocking," but "bloeked" once too often, for the ball went above, instead of below, and the bails came off. That was a pity, for he had not then scored. However, he was not alone in that respect. The game was generally interesting, and so satisfactory that Mr. Marshall intimated at the conclusion that he had received invitations from two prominent horticulturists for separate matches next year, and he trusted that the cricket meeting might become an annual affair. The umpires were Mr. S. T. Wright and Mr. Thomas Humphreys, to whom a vote of thanks was accorded.

Luncheon was partaken of in a large tent erected in the grounds, at which thanks were conveyed to the owner of Gunnersbury Park for his courtesy in having permitted the visit. In the company were noted Messrs. H. B. May, George Paul, John Wright, — Harrison (Leicester), J. Assbee, J. James, and A. Dean. The teams and scores were as follows:—

| FRUIT AND VEGETABLE COMMITTEE. |             |                  |                  | FLORAL COMMITTEE. |               |  |  |

### Edinburgh City Gardens.

That new brushes sweep clean we are agreed, and changes in the superintendence of gardens, public or private, sometimes or indeed very often, result in alterations to the aspect of the grounds or in their routine display. The old order changeth, and the desires of to-day are other than those of yesterday. This leads me to say that Mr. J. W. McHattie, City Gardener in Edinburgh, has altered and improved the aspect of the bedding scene this year in Prince's Street Gardens. New beds entirely have been planned; old walks have been displaced, and a different style of bedding been inaugurated to that of years past, but of which I may write under another head.

The bedding this year is sub-tropical in character, and met with general approbation, although one friend of the old school with whom I spoke lamented that there was no "show," no blaze of flowery colour. But while the foliar effects subdue the brilliance begot of flowers by themselves alone, I, and others, were well content with the "show" made by *Violas* in the fresh made borders of sinuous outline which enliven the forefront of the sombre shrubbery by the railway route, where the centre of the ancient Nor' Loch lay. And by a shaded nook by the Waverley

Bridge, till the present year a sort of nursery-keep, the City gardener will soon present the citizens of my native hold with a Bamboo garden, which one has every reason to expect will become a successful and delightful feature. On those steep grass banks supporting the topmost terrace, next spring will see designs thereon, in *Crocus* hues, and soon the little corns will find their place within the soil. Shields, stars, and circles are the designs suggested.

Then there is the fountain end to be kept in mind. Pathways near this spot are to be renewed, and shrubberies replanted. £1,000 are being spent on new shrubs. Old friends returning will ask where they are! Who shall know the gardens? At Blackford Hill, where the city boundary is, the Japanese *Rugosa* Rose has been liberally planted, and certainly from a distance I admired the Golden Elder on its basal slopes. Water Lilies are to adorn the basin of the fountain in Prince's Street Gardens, and Daffodils are being naturalised on the wooded slopes beneath the crags of high-placed Edinburgh Castle. History and Art! yea, and Commerce too—remember the railway lying between.

But these are sufficient in the way of change to go on with. The most enterprising must be satisfied, and the dour conservative must set his teeth. Yet must we still gaze sadly eastward from the Castle Esplanade or Calton Hill to the barren slopes of crumbling basalt that unadorn those "Samson's Ribs?" The Crown authorities must emulate the City.

### Trinity Grove, Edinburgh.

The Poet Laureate most interestingly describes what joys and pleasures the little garden that he loves—*Veronica's Garden*—possesses and accords to him, but his sunny southern garden does not, I am sure, surpass in any one respect whatever, that wondrously fertile and cosy Eden nook surrounding the quaint old residence, once, of Queen Mary of Scots, and later in time, of Sir Walter Scott, which is to-day named Trinity Grove, Edinburgh. I am inaccurate to address it under Edina's sway; it lies within the postal district of the Port of Leith, and Provost Mackie of that seaport is its present owner. But Edinburgh and Leith here join, and the Grove may mark the northern limit, for a few yards further flows the Firth of Forth.

Trinity Grove has attracted the horticultural journalist much oftener than twice or thrice, and that lover of the beautiful in either art or Nature, the late revered David Taylor Fish, made frequent pilgrimage to the Grove, and his delight at the square Yew hedges—growths of many years—at the Cedars on the lawn, the mighty Poplar by the gate, the umbrageous, half-inclining, mossy old Pear tree by the bowling green, and which never fails to fruit, was always renewed, and with the Apple trees on the vegetable brakes, and the fruitful Grape Vines and Peaches under glass were a perennial source of pleasure.

Provost Mackie and his family are also truly fond of this unsurpassable garden, and duly appreciate its bounty. Grapes I have mentioned, and Peaches. Lo! for years they have borne a plethora of fruit, and still their vigour and prolificacy remain as great, or greater, as it almost appears to me who have known this garden over now a long period. It is difficult to say whether the Peaches or the Vines do the better. Certain it is, each are model houses of the ablest cultural practice, and by no other means than the constant and skilled attention of the gardener during his twelve years of office, could they have remained thus in excellence for so long a time. When I say that the experienced manager of Methuen's nurseries has been proud to bring a wealthy client down to the Grove, that he might see "What one of our men" can do. Pointing to the laden trees, the testimony need be carried no further. "One of our men," in this case, meant that Mr. A. McKenzie, the gardener, was a dealer with the firm.

Apple trees in the open are clean and in good heart. They bear so heavily that but little annual wood is made, and consequently the shoots are stout and well ripened. The sandy loam assists towards this condition, but it necessitates both a liberal supply of manurial enrichment, and of watering during a droughty summer. The Celery trenches have frequently the hose upon them, and so, too, have the Strawberries and the Roses. The Rose garden is a formal one, laid out in long beds, and surrounded on three sides by part of the beautiful hedges I referred to earlier, and the fourth side upholds espalier Apple trees, and a new Honeysuckle arch. Crimson Rambler and other suitable Roses have been set upon arches at the crossings of the walks, but these so far, have not fully succeeded. South and east of the rosery lie borders of Spanish and English Irises, beds of Dog's-tooth Violets, lines of perennial Phloxes, and a great profusion of the handsomest old-fashioned herbaceous flowers, not omitting giant clumps of the creamy Plume Grass.

There are other features which never fail to attract the visitor, and these are, first big Gooseberry bushes; and next a splendid Niphetos Rose which covers the whole inner surface of a moderate-sized span-roofed greenhouse, and on the roof of the indoor fern-rockery, a notable *Passiflora racemosa* screens many square yards with foliage and flowers which are present the whole year round. We are pleased to know that this interesting place of monastic mien is now in the hands of the respected Provost, and trust that he and those around him may long dwell there to enjoy its delights.—WANDERING WILLIE.

### Peasgood's Nonsuch Apple.

I have made great efforts to succeed with this magnificent Apple, but cannot yet say I have attained my wishes. I am aware they are longer in commencing to bear than most varieties, but when they do the patience of the grower is rewarded. A specimen that I lifted and root-pruned last autumn is now covered all over with lovely blossoms. I should like to ask some of your readers, should I take off those blossoms now, or will it prevent fruiting next year?—W. J. MURPHY, Clonmel.

### Mutations of Seasons.

The article which appeared under the head (September 4, page 214), discussing "the untoward nature of the weather this season," suggests a subject at once interesting and seasonable. I do not, myself, detect any deterioration of the climate of our island, and I have made weather notes and observations for now well nigh fifty years. I incline to the theory of cycles, and the opinion that, roughly speaking, a seven years' dry time is followed by a seven years' wet; and that this is probably now being the case. People in general, I think, have rather short memories regarding the weather, and reference to old journals will usually show that what we are denouncing as unprecedented is very much the reverse. At the same time, it must be admitted the weather has of late become demoralised to a very high degree, perhaps even to an unusual extent, and the terrible atmospheric disturbances which have taken place, and alas! are taking place, may very possibly have something to do with this. I can remember far worse seasons, where whole fields full of stooks showed a bright ring of green where the Corn was sprouting, but scarcely one marked with all the present phenomena. "Great earthquakes in divers places" are a well known prescribed feature in an approaching "end of the age."—A. C.

### A Good Crop of Raspberries.

In a season when the hardy fruit crops are so unsatisfactory in general, it is pleasing to have an exception to the rule. The only really good crops here have been Peaches, Gooseberries, and Raspberries. The latter has been an exceptionally good crop, a few details of which may be of some interest to readers of the Journal in this special fruit number. I may say that the canes are grown in the ordinary way, the stools being 4ft apart between the rows, and the same distance from each other in the rows. About six canes are allowed to each stool; these are pruned to three different lengths, the longest to about 4ft, and the shortest to 18in from the ground. By this method fruit is produced from the bottom to the top of the stool. The fruit on the lower part is somewhat shaded and protected from birds, and will, consequently, hang longer. Superlative is the variety grown, and is one of the best Raspberries that can be had for productiveness and appearance. The flavour, however, is not so good as some other varieties. In some localities it produces canes rather sparingly. Here just the reverse is the case.

The plot in question consists of three rows about 30yd long, each row containing twenty stools, or a total of sixty stools. They cover an area of 120 square yards, or about one-fortieth part of an acre. The actual weight of fruit gathered was 12 stone; this gives about 2½lb per stool. In this neighbourhood the retail price is 4d. per pound. The value of the crop would, therefore, be £2 16s. In the "Fruit Growers' Guide" an average crop of Raspberries is stated to be 1½ ton per acre, or from canes in full bearing 2 tons per acre. The crop here is considerably above the latter weight, working out, I find, to no less than 3 tons per acre. The value per acre at the same price, 4d. per pound, would be £112. No record has been kept previously, so cannot say how the crop this season would compare with other years. As the crop was a good one all the fruit was weighed as soon as gathered, with the above result. The fruit was not netted, consequently the birds would get some, and a quantity was destroyed during a very wet week, when it could not be gathered, or the crop would have been even greater than it was. I might add, that last year when it was so very hot, and everything dried up, this Raspberry stood the test well, giving a good crop, and the fruit lasting a long time in good condition.—J. S. U.

### Lilium giganteum.

At different times a good deal has been said about *Lilium giganteum*, but still it may be of interest to many of your readers to know how this fine Lily thrives in the west of Argyll. One specimen at Achmama, the property of Colonel Malcolm of Poltalloch, reached the height of 10ft, the circumference round the stem at ground level 13in, a fact I think worth recording. At the same time, at Poltalloch, the residence of Colonel Malcolm, three bulbs in a group flowered, the tallest one reaching the height of 8ft, with fifteen flowers. They grew in a border which cannot be called shady, but fairly rich in vegetable matter.—D. S. M.

### The Conference Pear.

I am very pleased to see you drawing attention to Conference Pear. The figure on page 230 is somewhat different from the great majority of my specimens, inasmuch as the fruit, as a whole, is gracefully curved on both sides—none straight. [Nor was ours.—Ed.] Shortly after the Pear Conference in 1885—after which it is named—the late Mr. Francis Rivers sent me a specimen, which has borne heavy crops in rather poor soil in my town garden ever since. This year it is about the only variety cropping fairly well. Such "old reliables" as Louise Bonne of Jersey, Williams' Bon Chrétien, Bergamotte Esperen, Marie Louise, Doyenné du Comice, and Jargonelle have small, imperfect fruits, or none at all. I have met none whose Pear crop is not sadly deficient.—W. J. M., Clonmel.

### Planting Conifers.

I fully endorse the remarks on the above subject made by "Pinus" in his "Notes on Conifers," on page 170. I have had under observation some Austrian Pines, English Yews, Retinosporas, and Cupressus, some of which were planted in autumn and some in spring. The latter in most, if not all cases, have done the best. The specimens were not large when planted, and were devoid of soil attached to the roots, as the majority of nursery stock necessarily must be in transferring it to a distance. Owing to the dry cutting winds, the plants received in spring were at once attended to by laying them in the heels to prevent the roots drying, and previous to planting the roots were immersed in water. The planting was carefully carried out, and a good soaking of water applied, followed by another during the drying month of April. Since then the weather has been propitious in regard to establishing newly planted trees and bushes. If a dry summer had prevailed, watering must have continued, otherwise they might not have fared so well. It is evident, however, that spring planting is reliable, and even safer than early autumn, for with a little judicious care good results must necessarily follow. There is little or no danger in transplanting trees with balls of soil from one part of the garden to another either in autumn or spring, or any suitable time during the winter. The details of planting described by "Pinus" are reliable, and if followed will ensure success in establishing the specimens.—E. D. S.

### One Reason why Gardeners should be Educated.

Having throughout the discussion on this subject, been very considerably interested, I experienced no small surprise that in its progress no one appeared on the scene to give effect to a phase of the question which your diffident servant the writer supposes to be a vital one. Though the average gardener claims the possession of an intellectual superiority over the members of some trades, it is doubtful if it is more than skin deep. It is needless to say that more than external polish is needed in the gardener. His avocations bring him in daily intercourse with a class—our British nobility—who, I say with pride, are pre-eminently the foremost in the world. Pedigree, education, and refinement are assuredly their inheritance, and it is by no means unreasonable to think that those, combining these invaluable qualities, would greatly appreciate, at least, a semblance of them in their servants who hold offices of trust and importance. How essential it is that such a servant deports himself in a highly creditable manner in the presence of a class who must be extremely sensitive to every little symptom of vulgarity or rudeness! To gain this high standard of excellence in one's conduct is not such an easy matter as one would suppose. It is the work of a lifetime, and without due regard to indefatigable studying and discipline, no one can ever hope to achieve it. No man of spirit would feel contented to rest under the stigma which brands the boorish one, or feel at ease beneath the appellation of puffed fool, the exponent of verbosity, or utterer of jargon. Truly the gardener must be a cultured gentleman. I am sorry to say many of them are not so; therefore the need for culture.—AGNO.

## Experiments with Plants.

The members of the St. Andrews and East of Fife Farmers' Club paid a visit on August 25, to Dr. J. H. Wilson's experimental plots at Greenside Nursery. The plots were reduced to a minimum size, the object being not to test the results of growing certain crops in large bulks, but to carry out with a few plants experiments which demand constant and close inspection. The series was planned primarily with the view of securing material for the University classes conducted by Dr. Wilson. The plots include a very complete set of agricultural grasses and Clovers, and also the less commonly cultivated plants, such as Lucerne, Sainfoin, Serradilla, Bokhara Clover, Comfrey, Chicory, Burnet, Buckwheat, Flax, &c. Attention is given to plant parasites and diseases. An interesting root parasite on Clover, the Broomrape, was in flower. This was established by sowing the seed of the Clover and the parasite together. The inoculation of Rye with ergot formed another very interesting experiment. The germinated ergots were new objects to the majority of visitors. Rust, smut, mildew, finger-and-toe, and sprain received a share of study. As is well-known, Dr. Wilson has long been an authority on plant hybridisation. Numerous new garden hybrids of value, including fruits such as Brambles, were seen in the nursery. In the plots was found a very remarkable series of vegetables derived from crosses between Brussels Sprouts and Broccoli, Savoy and Brussels Sprouts, Curled Kale and Broccoli, &c. The object in crossing these was twofold—to gain insight as to the effect of deliberate intercrossing of the varieties of the Cabbage family in the matter of reversion to the old stock, and, if possible, to secure new races of vegetables. The new plants were extremely vigorous, and presented bewildering variety of shape and tint. A remarkable hybrid between Curled Kale and Charlock was in flower. It partook most of the latter parent, but was much taller. Crossed Swede and yellow Turnips, and crosses between these, were in abundance, and were regarded as very promising. A large number of crossed Potatoes was noted. Although only sown in the middle of March last, the plants are expected to bear a full crop of tubers this season. Many were in flower, and the stems of many were 3ft. high. It was instructive to find a great variety in colour of leaf, flower, and tuber in seedlings from one and the same fruit. The most remarkable objects in the plots, however, were probably Dr. Wilson's new hybrid Oats. They were the result of six distinct crosses, including white Canadian, English Potato, Waverley, &c. All presented most surprising vigour; indeed, it was hard to believe that the new plants were from single grains sown at the same time and grown under the same conditions as the parent Oats seen alongside. The tallest—Goldfinder crossed with English Potato Oat—reached the height of 7ft 8in. The heads of the hybrids were commonly enough 18in long, and in one case the number of grain-bearing stems produced by one plant was twenty.—("Dundee Advertiser.")

## A Classification of Sweet Peas.

For a considerable period the committee of the National Sweet Pea Society has been of the opinion that it was desirable to formulate some scheme of classification, and at the recent most successful show this was demonstrated in a very forcible manner. It was apparent that the growers were not in harmony in regard to the colours of many varieties, while some which were staged in one special colour class were also represented in another which should have been totally dissimilar. It was obvious that some remedy for such an anomalous state of affairs was essential, and it was procurable only by an election of varieties which classified them under specified colours.

At a meeting of the executive committee, held on July 29, it was resolved that classification papers be printed and distributed amongst members of the committee, as well as growers of repute, whether they were members of the society or not. It was clearly seen by the committee that the date of distribution was fully late, as many varieties were so far past their best that some of the colour and form characteristics were rapidly failing. The necessity for the work was, however, so very imperative, that this disadvantage had, perforce, to be overlooked, and the committee relied upon the wide knowledge of those beautiful flowers, known to be possessed by the gentlemen who filled in the lists. Nor was this confidence misplaced. It was speedily found that there was a strong consensus of opinion in favour of the best varieties, and it was only when we came to unimportant, and often variable varieties, that any material divergence of opinion was manifest.

The committee is convinced that the varieties which occupy the first, second, and third places under the several colour headings—and to which the votes each received are attached—are the best of those in general cultivation. Several varieties, like Dorothy Eckford and Countess Spencer, would have received

many more marks had they been known, and to this fact alone must be attributed the positions they occupy in the accompanying tables. The committee desires it to be fully understood that this is its first attempt at classification, and that it was made late in the season, in consequence of which it may be subject to expansion, emendation, and general improvement in future seasons. Many growers have asked for lists of the best twelve, twenty-four, and thirty-six varieties to be embodied in the schedule of next year's show, and these the committee will prepare in due course, though their necessity is reduced by the appended tables.

It will be observed that in each case a certain number of varieties are above and a certain number below the line; the latter are there placed either because they have been superseded by others above the line, or because they are not sufficiently well known for an authoritative opinion of their merits to be expressed. One or two sorts that were inserted in the election papers have been excluded because absolutely nothing was known about them. Growers are assured that any variety they consider misplaced this year will find its proper level in the classification of the Sweet Pea that, it is hoped, the National Sweet Pea Society will annually undertake.

As the annual meeting of the society will not be held until January, there was a clearly expressed desire that the results of the work of the committee be published early, so as to enable the seed merchants to include them in their catalogues in the form of recommendations, as they are, by their positions, proved to be of superior merit. The committee, therefore, request the co-operation of the gardening Press, which has done so much to further the interests of the society, to add to its kindness by giving publicity to this election.

9 Coccinea

according to the character of the soils, giving the results of the different varieties from each centre. Other hardy fruits were classified in the same way, and the effect of the different characters of soils upon Strawberries were most strongly marked, as shown by the reports.

In conclusion, the lecturer said the hardy fruit industry in Yorkshire might become a more important one than it is at the present time. There is much land in various parts of the county well suited to their growth. In private gardens, good hardy fruits are often grown under the most difficult conditions, but only under exceptional cultivation, the cost of labour and material being only secondary considerations. When planting for market purposes in a county like Yorkshire, special attention should be given in the choice of suitable soils, sheltered positions, and in the selection of those varieties of fruits suitable to the climatic conditions, as mistakes were easily made, with the result that the profit and loss account afterwards would possibly be represented on the wrong side of the balance-sheet.

## Tomatoes for Early Fruiting.

In many establishments there is no convenience for raising sturdy Tomato plants for early fruiting, the house in some cases being too lofty, and others too dark. To overcome this difficulty seeds should be sown early in September and allowed to germinate under cool, airy conditions. When a few leaves are formed pot them into 3in pots, placing two plants at the sides of each pot opposite each other. So soon as the plants have taken to the soil let them be fully exposed to the light in a cool, well ventilated house in order to secure sturdy, short-jointed plants. They must not be exposed to cold draughts, or allowed to become stunted for want of root room.

To prevent the latter, pot the plants into well-drained 5in pots as soon as the 3in pots are full of roots, and everything should be done to secure the happy medium between a sappy, lanky growth and a thin, starved, sickly plant. The compost should consist of four parts medium fibry loam, and one part either mortar scraps or charcoal, ranging from powder to portions the size of horse beans. With attention to other details, which will readily suggest themselves to the observant cultivator, we shall have sturdy plants ready either to pot into fruiting pots, or to plant in a narrow shallow border by the first week in January. As most of the plants will be showing one or more bunches of blossom, and in some cases have fruit set, with a suitable house and good management fruit will be ready for use early in April—a season of the year at which every addition to the vegetable list is exceedingly useful and highly appreciated. Moreover, armed with a batch of plants of this description, the cultivator is under no necessity of trying to raise substantial plants at a season when the days are short and dark, conditions which often render his best efforts futile.

There are so many good varieties of Tomatoes now on the market, that it is difficult to mention any one as the best for general cultivation. For late winter and early spring fruiting we have found none to equal Sutton's Winter Beauty. The fruits are a little rough, especially the earlier ones, but with due care it sets freely and produces very heavy crops. A hint may be here given regarding the pollination of Tomatoes in winter, as owing to the prevailing dull, damp weather, the best varieties may fail to set a full crop without extra trouble on the part of the attendant. Brushing the blooms with a camel's-hair brush is not always reliable, simply because the dehiscence of the anthers is "porous," and hence the pollen can only escape through small openings at their apex.

### Pollination of the Tomato

would be far more effective at any season of the year were the dehiscence of the anthers longitudinal, as is the case with the *Amaryllis*, *Liliums*, and indeed the majority of flowers; and this is a structural defect which raisers of new varieties should endeavour to breed out. The present dull, wet season has borne testimony to the urgent need of a race of Tomatoes whose pollen grains may be more readily dispersed, as on all hands complaints are being made that the plants have not set good crops, especially in the early part of the present season. When the weather is bright, and the air in the house dry and buoyant, gently tapping the plants is more effectual than brushing, but we so seldom get these conditions during the first two months of the year, that it is best to resort to more certain methods, as to lose the first bunches of fruit would largely nullify our previous efforts.

In the late and early months of the year we take it for granted that neither brushing the blooms nor tapping the plants are reliable. The safer plan is to remove the anthers entirely soon after the flowers are fully opened. This is best done by using a pair of fine-pointed forceps, care being taken not to injure any part of the gynoecium—that is, the stigma and ovary.

The anthers should be placed on paper in a warm dry position. Twenty-four hours will generally suffice to dry up the moisture

## Hardy Fruit in Yorkshire.

A lecture was delivered on September 2 by Mr. Alfred Gaut, of Yorkshire College, Leeds, before the Royal Horticultural Society, upon the growth of "Hardy Fruits," in which he said Yorkshire, taken as a whole, is subject to much variation in climate and temperature. The physical configuration of the county has a great bearing upon its hardy fruit culture. High, barren mountains and hills, with their sides sloping to all parts of the compass, numerous sheltered vales, and flat open country, in places near the sea level, are its main features. Bounded on the east and north-east by the German Ocean, it is much subjected to cold winds and fogs coming off the sea, and fruit trees, especially when in flower, suffer much from these causes. Where the coast is low and bleak, these influences are felt for some distance inland, while in the more sheltered vales, especially when well wooded, the fruit crops do not suffer so much. On the west the Pennine Chain runs the whole length of the county, and the westerly winds, sweeping down from these high altitudes, are rather cold, and this naturally has a retarding influence upon the hardy fruits in the vales. Towards the north the country is open and exposed, and, from this quarter the winds sweep down the vale of York. This shows what an important factor good shelter is to successful fruit culture in Yorkshire.

The geological character of the surface soils and subsoils is as strongly marked as its main physical features. Anyone well acquainted with the county can easily trace out the main lines of the chief hardy fruit growing districts. These extend from the north, down the great central vale of York, sweeping round by the vale of Pickering, following the Ouse valley to the mouth of the Humber, and over the flat alluvial plains by Thorne and Doncaster, and also along the main courses of the rivers. Continuing his remarks, the lecturer spoke of the large Pear trees between Thirsk and Gilling, one as measured, being 46ft high, and large in proportion; the fruit industry and the soils in the Pickering valley, a large Strawberry farm at Sutton-on-Hull, and samples of fine Apples, as grown near York, Selby, Thorne, and Barnsley; the noted Yorkshire Winesour Plum and the Whixley Cherries, and the effects of smoke from the chimneys of the collieries and factories upon the trees. All the various lists of hardy fruits were arranged under tables by the lecturer, and classified

and render the pollen free and powdery. By means of a couple of needles fastened into small sticks the anthers may be dissected so as to expose the pollen chambers. The pollen may then be shaken upon paper, or a small camel's-hair brush may be loaded with the grains by brushing the dissected anthers. Having thus secured abundance of pollen, the stigmas may be pollinated by carefully brushing them with the pollen-laden brush with every confidence of securing a good set and early crop, which will be an abundant reward for the extra trouble taken.  
—J. H. W.

## Literature.

### Orchard and Bush Fruit Pests.\*

This cheap little pamphlet contains a good deal of information which may be very valuable to the gardener, and deserves to have an extensive sale. Suggestions are made for the prevention of insect attacks upon fruit crops, and a good selection given of insect killers, some of them very powerful.

We may remark, however, that, as a matter of individual opinion, we object to the poisonous compounds in which arsenic or copper figure. We think sometimes of a remark made by Mr. Abbey in this Journal, that, after all, you can hardly have a better remedy for most insects than clear rain water, applied in a fine stream or spray.

One observation of Mr. Warburton's all gardeners would do well to lay to heart, that there is a period in the history of each troublesome insect when it is, so to speak, delivered into our hands. That is the time to take prompt measures, not when the damage done by it is prominent, and yet it cannot be so easily destroyed. In notes upon the winter moth, the author does not refer to the presumed fact that the males sometimes bear their companions upwards to oviposit, thus rendering the sticky applications of little use. We do not expect a small book like this to be comprehensive, but we are surprised two such well known residents on fruit trees as the lackey and the small ermine caterpillars should be unchronicled. In briefly describing, too, the Black Currant mite, allusion might have been made to the kindred species, which much disfigure the Pear and Plum.

#### Publications Received.

"Nature Study Journal," No. 4 contains a Romance of a Museum, a Country Walk, School Gardens, a Spring Walk, &c. \* \* "Le Moniteur d'Horticulture," July 10, has a coloured plate of *Kitaibelia vitifolia*. ## Societies.

### R.H.S., Scientific Committee, September 2nd.

Present: Dr. Masters, F.R.S. (in the chair), Dr. M. C. Cooke, Dr. A. B. Rendle, Messrs. E. M. Holmes, J. Douglas, Odell, Rev. W. Wilks, and Mr. Gaut (visitor).

*Phyllotaxis of Aloysia*.—Mr. Odell brought specimens showing variations in the number of leaves to a whorl on different shoots. On the secondary shoots, which resulted from the pinching of the primary one, the leaves were in whorls of three.

*White Lavender*.—Mr. Odell showed flowers of this variety to exemplify their fragrance, which had been disputed.

*Double spathe of Richardia Elliottiana*.—Mr. Douglas brought a specimen of a double spathe in this plant, in itself not an uncommon occurrence, but the spathes in the present examples were remarkable for being deeply pinnately lobed.

*Helianthus Miss Mellish*.—Specimens were exhibited showing the decay and rotting of the root-stock and stem apparently due to fungus "sclerotia," which were found in the tissues. Dr. Cooke undertook to report on the specimens on another occasion.

*Peloria in Antirrhinum*.—From Mr. Lorenz, of Erfurt, came specimens of regular flowers of this plant. The regularity in this case is owing to the increase of the irregular portions, so that there are five spurs instead of one only, thus constituting it a case of irregular peloria. Mr. Lorenz has succeeded in "fixing the variation and inducing the development of a race."

*Celery Leaves*.—Some specimens were affected by a fungus allied to *Phyllosticta* or *Sphaerella*.

*Twin Cucumbers*.—A specimen of this not uncommon peculiarity was exhibited. The appearance is probably due to the union of two flowers in a very early stage of their development.

*Cracked Pears*.—Specimens were shown showing the effect of *Fusicladium* in arresting the growth of the rind of the Pear, which cracks as the flesh beneath increases in bulk. Spraying in an early stage is the only means of preventing the mischief.

*White Heather*.—Mrs. Streathfield sent specimens of the white variety of *Erica Tetralix* from a Surrey common.

*Silver-leaf disease*.—A letter was read from Professor Percival: "From sections of the stump through the points of union of scion and stock, it seems very probable that the fungus which causes the disease had entered at the point of grafting in this particular case. Such examples are not at all uncommon, although in many cases the disease starts in the roots below ground. The disease, I have abundantly proved this year in my own garden, can be induced with the greatest ease by inoculating any part of the tree either above or below ground. The fungus (*Stereum purpureum*) does not itself extend very far in the tissues of the diseased trees, but some of its products, or products resulting from its action on the tissues of the trees, circulate rapidly in an upward direction, and induce the peculiar changes in the leaves. Downward circulation also takes place, but much more slowly. In several cases of inoculation with the fungus on long branches of plants, the disease has spread downwards even after the greater portion of the branch has been cut away at a point several inches below the point of inoculation."—John Percival.

*Copper as a cause of yellow foliage*.—Mr. Gaut alluded to the yellow tint assumed by the foliage of certain Apple trees in Yorkshire. The want of colour had been attributed to the presence of copper in the soil, but as it was considered that the evidence in support of this opinion was inadequate, further information was solicited.

*Melan disease*.—Mr. Willard sent specimens of this disease, characterised by rotting of the bine, and attributed (conjecturally) to the presence of bacteria. Acting on a suggestion of Dr. Masters, Mr. Willard had inoculated a seemingly healthy plant with some of the juice from a diseased plant. The result was the development of disease within a very short time. The committee, however, thought the result of the infection would not have manifested itself so rapidly, and that the inoculated plant would shortly have shown symptoms of the disease even if it had not been inoculated.

### National Dahlia, Sept. 2nd.

From the hon. secretary we have received the following list of special awards:—Silver Medal for best bunch of Cactus Dahlias in trade classes to Messrs. Stredwick and Son for Miss F. Stredwick.

Silver Medal for best bunch of Cactus Dahlias in amateur classes to Mr. P. W. Tulloch for Mrs. Mawley.

Bronze Medal for best New Show or Fancy Dahlia to Messrs. Keynes, Williams, and Co. for Henry Clark.

Williams' Memorial Medal awarded to Mr. L. McKenna for twelve bunches of Cactus Dahlias (amateurs).

Silver Medals for single Dahlias awarded to Messrs. J. Cheal and Sons; Mr. F. W. Seale; Mr. J. F. Hudson.

Non-competitive Exhibits: Silver-gilt Medals to Messrs. Cannell and Sons, to Hobbies, Ltd. Silver Medal to Messrs. Cutbush and Sons. Bronze Medal to Messrs. Jones and Sons. Vote of thanks to Messrs. Barr and Son, and to Messrs. Smith Bros.

### Reading Horticultural.

The Reading Horticultural Society held a successful exhibition on Wednesday, August 26, being favoured with fine weather. The numbers who paid the highest price for admission were larger than they have been for a long time, whilst at the close of the day there were about 5,000 present. But whilst the show was well supported by visitors, it cannot be said that the society was as well supported as it might have been by the exhibitors, or rather by those that should have been exhibitors. Many familiar names were missed from the show cards.

For quality the vegetables in competition for Messrs. Sutton's prizes made the finest show seen anywhere this year in England. The entries fell considerably short of last year, only 400 exhibits being staged, against 540 the previous year; but the unfavourableness of the season, which has manifested itself at every show, easily accounts for this, whilst it must be remembered that the entries for the year before last only numbered about 400. For the Society's Challenge Cup, valued at 20 guineas, three groups were sent in for competition against five last year. Mr. F. D. Lambert, of Moor Hall, Cookham (gardener, Mr. Fulford), had previously carried off the trophy twice, and again won it. He thus is possessor.

In the open cut flower classes the Dahlias and the "bunches of twelve" were most noticeable. The former were very much admired, especially those sent in by Mr. J. Walker, of Thame, who was an easy first for the Show, single, and Cactus varieties with some magnificent blooms both in colour and perfection of natural arrangement. Messrs. Cheal and Son, of Crawley, took second. Mr. R. Moss, Hawley, Blackwater, was third for single and Cactus varieties, but he excelled in his bunches of cut flowers, which were magnificent.

Fruit made a good show considering the season, some fine Grapes coming in for a good deal of attention. Especially noticeable were three fine bunches of Muscat of Alexandria, which were much admired for their colouring, although this is a bad year for colouring. They were shown by Mr. Galt, gardener to Mr. Keyser. Sir Charles Russell's noted Black Hamburg variety were also conspicuous, and they gained first prize. Some extraordinary good Peaches (Sea Eagle) from his gardens were also first prizetakers. Culinary Apples were fairly good. Quite the tit-bit of the show was the vegetables staged for competition in Messrs. Sutton's prizes, and experts say that nothing has been seen in England to beat them this year. Mr. R. W. Hudson, Danesfield, Marlow (gardener, Mr. Gibson), had a collection, every specimen being typical of its kind. The Right Hon. Lord Aldenham, of Aldenham House, Elstree (gardener, Mr. Beckett), made a good second, but was a little weak in Beet, Carrots, and Parsnips. Sutton's New Red Intermediate Carrots in Sir Wyndham Portal's exhibit, which got fifth prize, were the best Carrots in the show; they were perfect models. There were some excellent Tomatoes on view in the open class, Mr. Hudson's Perfection (Sutton's) being splendid specimens. The Forbury Gardens were looking their best, and were much enjoyed by the visitors.

There were several entries not for competition, which were not the least attractive features of the show. First mention should be made of a large, magnificent group shown by Messrs. Cutbush and Sons, nurserymen, of Barnet and London. For variety and quality of blooms the group would be hard to beat. Messrs. Cheal and Son, Crawley, had Cactus Dahlias, and George Prince, Roses.

### Liverpool Amateur Gardeners.

Hospital Night is always a great event in the history of this progressive society, and the inmates of the Children's Infirmary, Myrtle Street, had a welcome surprise when on the following day they found the wards completely transformed by the exhibits, which were all sent up by the members on Thursday last. Cactus Dahlias, considering the season, were remarkable, no fewer than nine staging. The first prize went to a new member, Mr. Wallace, with an almost perfect collection; Mr. Robins the second. For Gladioli, Mrs. McGregor was first. This lady was first for an epergne composed of pink Carnations and Gypsophila; also for superior cut flowers and Asters. Mr. Hitchmough had a capital show of Dahlias, Asters, and Tomatoes, and Mrs. Stevenson a choice Fern. The second prize for Tomatoes is worthy of special mention, being grown by Superintendent Muir, of the Hatton Garden Fire Station, in a small roof greenhouse. Mr. Ellison had the best cut blooms, the leading plant in bloom, a tuberous Begonia, coming from Mr. Wallace. A special prize for the most suitable gift of flowers, fruit, &c., was offered by Mrs. Muir. As this might be an inspiration for other shows to help a good cause, I quote chief contents: A chicken, bunch of Grapes, bunch of Bananas, Apples, Pears, handsome selection of scrap books, flowers, &c. This from Mrs. Morris. Miss Davies and others exhibited well. A good number of fresh eggs were sent by Mr. R. Muir, of Formby. The annual excursion for members was held last week, by the kind permission of the Hon. W. Walsh in Knowsley Park, the beautiful seat of the Earl of Derby, K.G. The party drove through many of the drives, the

scenery of the distant country being much admired. One of the garden staff had been deputed to escort the party through the grounds, which at the present time are quite delightful, the Rose garden evidently causing pleasure. Substantial refreshments were then served, after which the party returned to Liverpool, much elated with all they had seen.—R. P. R.

### Sandy and District, August 28th.

This show was held in the Park of Sandy Place on the above date, and proved to be one of the most successful shows that had ever been held. The competition was very keen. The class for ten stove and greenhouse plants went to Mr. Cypher, he showing in his usual form. The groups were a strong exhibit, the first prize going to Mr. Finch with a very neat and tasteful arrangement. Roses were fine for the season, and both classes fell to Harkness and Co., followed in each class by G. W. and H. Burch, Peterborough. Dahlias were very fine, Keynes, Williams, and Co., and other well known growers, taking the lead.

Sweet Peas were largely shown, and R. M. Bradley, Peterborough, proved to be the best exhibitor, closely followed by W. and J. Brown, Peterborough. In the smaller plant classes, where nurserymen are excluded, for six foliage plants, Sir A. Marshall (gardener, Mr. J. Humfries) led, and stove and greenhouse Ferns also went to the same exhibitor. Among other successful competitors in this class were Lord Peel, of Sandy Lodge; Mr. Leeds Smith, Mrs. Astell, and Miss Goodgames, St. Neots.

Fruit classes were very strong and well filled. The collection of eight distinct brought six entries. The first award went to the Earl of Sandwich, Hinchbrook, Huntingdon (gardener, Mr. J. Barson), the Black Maroc Grapes being very fine, Muscat of Alexandria good in berry, but scarcely finished, Sea Eagle Peach good, Nectarines fair, and all other dishes good. The second prize went to Mr. Harsley, Hemel Hempstead (gardener, Mr. Folkes), whose Grapes were very good, excellent Golden Queen and Alnwick Seedling, but his single dishes were poor; third, Captain Duncombe. In the class for six distinct dishes, the first prize went to Col. Shuttleworth, Old Warden Park (gardener, Mr. W. C. Modral). This was a neat, clean, well-set-up exhibit, and far before the others in the class. The second prize went to A. J. Hornill, Esq. (gardener, Mr. T. Lockie); third, G. D. Newton, Esq. For a collection of Apples (very small this season) the awards went to Captain Duncombe, Warsley Park (gardener, Mr. Carter); and second, Mr. Carlile. For two bunches Black Hamburg Grapes; first Mr. Carlile, and second Mr. C. Moore, St. Neots. Any other black, first Mr. Folkes, with excellent Alnwick Seedling; second, Mr. C. Moore, St. Neots. Muscat of Alexandria, first Mr. Barson, with well finished bunches; second, Mr. G. E. Foster. Any other white, first Mr. Folkes, with Golden Queen (good); second, Mr. Barson, with Mrs. Pearson; good bunches but not quite finished. For both inside and outside Peaches Mr. Barson led, and with Nectarines inside and out Mr. Lockie led. The best dish of outside Figs I have seen for a long time was exhibited by Lord de Ramsey, of Ramsey Abbey (gardener, Mr. F. Seabrooke).

Vegetables were extra strong. Sutton and Sons' special prizes went to Mr. Lockie; second, Mr. Folkes. Carter and Sons', first Mr. Folkes; second, Mr. Barson. Webb and Sons', first Mr. Folkes; second, Mr. Barson. Society's prize, first Mr. Barson; second, Mr. Carter. Collection of Potatoes (very strong class), first Mr. Barson; second, Miss Fitzpatrick. Cucumbers were well shown by Mr. Lockie, and Tomatoes made an excellent entry. The first prize went to Mr. Barson, and the second to Mr. Humfries. Many other exhibits were worthy of mention but space will not allow of it.

### Preston Guild, Sept. 3rd.

The great Preston Guild, an event which only takes place every twenty years, is past and gone, and it may be truly said that a more wonderful pageant than that made by the processions could scarcely be realised. Then, too, the visit of the Royal Agricultural Society, with its record entries, in the Moor Park, was a great attraction; the Potatoes and root crops from all the leading seedsmen in the kingdom being amongst the best ever seen.

In the midst of so much variety it is only natural that horticulture should play its part, and with such patrons and lovers of the study as the Mayor and Mayoress (Lord and Lady Derby) the committee were justified in getting together a valuable and interesting exhibition. Tuesday night's storm had displaced some of the canvas, but by the time of staging no fault could be found, the three large marquees being filled with a really fine display of flowers, fruits, and vegetables.

One missed the familiar face of the late Mr. W. Troughton, but his son filled the breach, and with Mr. E. Payne, as secretary, the work was well carried out. There were three classes for groups arranged for effect, that for 300 square feet going to Mr. Troughton. Palms and Ferns formed a special feature in that for 200 square feet, also won by Mr. Troughton. The leading prize for the amateurs' group was accorded to Mr.

W. Haynes, gardener to Mrs. Calvert, with a most tasteful arrangement: Mr. J. B. Dixon following with excellent material not so well put up.

Preston contains many good collections of British Ferns. The six from Mr. J. B. Dixon, and three from Mr. J. Ashworth rivalled many of the exotics. For six exotic Ferns, six foliage and flowering plants, one Tree Fern, and three Dracænas, Mr. J. B. Dixon showed capital plants. Mr. C. Parker, an Orchid authority, won for the best Orchid in bloom.

For six dishes of fruit, his Muscat of Alexandria and Black Hamburg Grapes, Peaches, Figs, Nectarines, and Melons made Mr. B. Ashton, gardener to the Earl of Lathom, a very good winner. The leading awards for Melons were won by Mr. J. W. Wearing, gardener to C. R. Brown, Esq., Windsor Castle variety being extra good. Mr. Ashton also won with six dishes of hardy fruits, and a superb dish of Cherries. Apple, Plum, and Pear classes went to Messrs. Guy, J. Smith, and J. Garside.

Cut flowers were magnificent. The table of 150 square feet from Mr. Troughton contained some brilliantly coloured Dahlias, Phloxes, Gladioli, Sweet Peas, Lilliums, &c. The arrangement was complete in every sense. Beautiful Orchids formed the cut flower prize won by Mr. C. Parker. Bouquets in choice variety were staged by Messrs. W. N. Wood, P. W. Heyes, and G. Morley.

All praise must be accorded Mr. B. Ashton for his superbly grown vegetables, for he won in the collections for twelve and six varieties.

Messrs. Little and Ballantyne, Carlisle, had Roses, herbaceous cut flowers, &c.; Mr. W. Bulman, Blackburn, Carnations; Mr. W. Shand, Lancaster, border flowers; Mr. J. O. Walker, Alpines, &c.; Mr. J. Saul, Pyrethrums; Mr. Titterington, Violas, Roses, Begonias; Mr. T. R. Hayes, Keswick, had splendid hardy Heath; and Mr. H. Middlehurst, Liverpool, Sweet Peas.

In the presence of a distinguished company Lady Derby, who was accompanied by Lord Derby, distributed the medals—two Gold Guild Medals, to Mr. W. Troughton; two to Mr. B. Ashton; and one each to Messrs. J. B. Dixon, R. Moss, H. Winwood, W. N. Wood, and H. Dewhurst. As the best exhibit in the show Mr. W. Troughton's winning group made him the recipient of a Silver Banksian Medal.—R. P. R.

## Royal Caledonian Horticultural, Sept. 10th and 11th.

(By Telegraph.)

The Edinburgh autumn show of garden produce, held under the ægis of this society in the Waverley Market, is recognised as being one of the leading exhibitions of its kind in the United Kingdom. The Council and promoters of it, must, on the present occasion, feel very well satisfied at having a display so large and excellent. The entries, we learn from Mr. Murray Thomson, the secretary, are very numerous, showing a total of 2,440 from 305 exhibitors. There are 221 competitors with collections of fruit and Grapes; 163 for small fruits; 411 for Apples; 96 for Pears; 124 for hardy small fruit; 217 for plants; 440 for cut flowers (groups are a leading feature); and the respectable total of 482 for vegetables. Add to these the amateurs' entries which number 195, and 91 competitive entries from nurserymen, and a fair idea of the extent and keenness of the contests may be obtained. One hundred and twenty-five of last year's exhibitors have not contributed to-day, but curiously true, there are 125 new exhibitors.

In all departments the exhibition equals, and in some features surpasses, those of recent years, in spite of the poor summer and recent storms. The whole area of the Market is crowded, and the sight beautiful and impressive. The fruit competition, of course, is the great feature of the show, the display being large, and the interest keen.

For a decorated dessert table, there are four competitors, all highly creditable. Mr. Dawes, Ledbury, gains first prize for fruit portion, with 93½ points out of a possible 127; Mr. Kidd, of Carberry Towers, Musselburgh, comes second with 93 points. The latter is again first for the decorated table (second not found), and Mr. Dawes, a good third. The latter, however, comes to the forefront for a collection of ten dishes of fruit, Mr. Murray, of Culzean, following as second.

The premier award for six bunches of Grapes is ably captured by that champion culturist, Mr. T. Lunt, of Keir, his lot being exceptionally fine. Messrs. Buchanan Bros., of Kippen, come second. For four bunches, the Buchanan Bros. lead, and Mr. Day, of Garlieston, makes a good second. This southern grower has beaten Mr. Kidd for Muscats; while for Black Hamburgs the Keir chief is again in the van. Mr. Fairbairn, of Alloa, is second.

For a collection of hardy fruits, Mr. Dawes succeeds to the premier place, with Mr. Binnie, of North Berwick, second; while for orchard house fruit Mr. Beisant leads off, followed by Mr. Dawes. A southern gardener—Mr. McKinley, of Amptill—is

accorded first for a collection of Pears, Dawes and Day taking the honours in this order for a collection of Apples.

In the plant division the quality of the exhibits is good, but not extensive. Mr. Knight, of Lenzie, wrested the first prize from the hands of Mr. George Wood of Oswald House, Edinburgh, for a group of plants. Mr. Sharp, of Freeland, well known as an orchidist, takes leading honours with these plants; while Lunt stages the best specimen foliage plants.

There is a large and very handsome display of cut flowers in all sections, Roses, curiously for the season, taking precedence. The nurserymen furnish a keen competition of these, Messrs. Cocker, of Aberdeen, taking first place for a collection of them; and second, Messrs. D. and W. Croll, Dundee. The first award for the three dozen Roses goes to Mr. Hugh Dickson, of Belfast, who can show late in the season as well as early. Messrs. Croll and Alexander Dickson and Sons, of Newtownards, are second and third; while for the eighteen we have Messrs. Dickson and Sons, first; and D. and W. Croll, second. For the dozen, Ferguson, of Dunfermline, has the best. Mr. Parlange, of Helensburgh, and Mr. M. Todd, Musselburgh, are accorded leading honours for Roses in the gardeners' classes.

Mr. M. Campbell, of High Blantyre, carried away the primary awards for Dahlias and Carnations, thus maintaining his good records as a florist.

The vegetables are clean and meritorious on the whole, the leading award in this section going south to Mr. Gibson, the Scottish gardener to R. W. Hudson, Esq., of Danesfield, Great Marlow, Bucks. His Cauliflowers, Onions, Carrots, and Turnips were perfect models. That grower of repute from Dollar, to wit, Mr. Waldie, is a good second.

### Non-competitive Exhibits.

Two groups come from Messrs. R. B. Laird and Sons, Ltd., of the Pinkhill Nurseries, Murrayfield, one consisting of a large collection of Conifers grown at their own nurseries, and embracing a great variety of ornamental kinds. The other group covered 600 square feet, and consisted chiefly of Lilliums—auratum, Harrisii, and lancifolium, with the beautiful Verbena Miss Willmott beneath, and graceful Dracænas, Crotons, and Caladiums, of each of which the firm has a choice and well-grown collection.

Messrs. Sutton and Sons, from Reading, hold a leading place among trade firms who are exhibiting. Their various popular strains of flowers are here included, and among vegetables they have splendid Onions, Carrots, and Tomatoes.

An exhibit of beautifully trained and tended pot fruit trees is forward from Messrs. Thomas Rivers and Son, of Sawbridgeworth, Herts. They stage Peaches, Pears, Grapes, Plums, and other subjects, the group attracting considerable public attention.

Mr. John Forbes, of Hawick, had a splendid exhibit of his now well-known herbaceous and hardy border plants, amongst which were some magnificent Phloxes in large variety. There were also a grand lot of well grown Pentstemons, with very fine spikes, bearing enormous circular flowers of every shade of colour. The newest and best Cactus Dahlias were also represented in very fine form. Carnations were also well staged in vases, and single blooms (nearly 300 of the latter), representing all the sections, were in themselves a feature of the exhibit.

The Kelso firm of Messrs. Laing and Mather contributes Carnations, including Sir Waldie Griffiths, Duchess of Roxburghe, and other novelties, all artistically displayed.

Mr. John Downie, of Edinburgh, has a table of Begonias; while Thomas Methven and Son, also of Edinburgh, have a group of plants.

Amongst those showing herbaceous flowers in variety and quality are Messrs. Dobbie and Co., Rothesay (who also have Dahlias, Marigolds, &c., Cocker and Son; Lister, of Rothesay; and Irvine, of Jedburgh. Messrs. Storrie and Storrie, from near Dundee, send their beautiful Celosia pyramidalis, and Begonias.

Messrs. Cunningham and Fraser, of Comely Bank nurseries, have an exhibit; and new Grapes of merit come from Buchanan Bros. Messrs. Thomson and Sons, of Clovenfords Vineries, Galashiels, are also forward with choice sample bunches from their Grape Vines. Mr. Hayes, of Keswick, has a beautiful table of hardy Heath.

### Awards.

Gold medals were accorded to Messrs. Rivers and Son, and R. B. Laird and Son, Ltd.

Silver-gilt medals to Messrs. Sutton and Sons; Thos. Methven and Sons; R. B. Laird and Sons, Ltd. (for Conifers); Dobbie and Co., Rothesay; and Cocker and Sons, Aberdeen.

Silver medals to Messrs. Laing and Mather, Kelso; D. and W. Buchanan; Storrie and Storrie; Cunningham, Fraser and Co.; and J. Phillips, Granton Road.

Small silver medals to Messrs. John Forbes, Hawick; and John Downie.

Bronze medals to Mr. Chas. Irvine, Jedburgh; A. Lister and Son, Rothesay; M. Campbell, Blantyre; and Hayes, of Keswick.

Cultural certificates were awarded to Messrs. Wm. Thomson and Sons, Ltd., Clovenfords; and D. Maclean, Raith, Kirkcaldy.

### Fruit Forcing.

**CUCUMBERS.**—The temperature should be maintained at 65deg by night, and 70deg to 75deg by day, with a rise to 85deg or 90deg from sun heat. Remove unhealthy leaves and old growths, and training the others as may be necessary. Employ the syringe sparingly, only damping the foliage on bright days, so that it may become dry before night. Damping will require to be done in the morning and again in the afternoon. Pot seedlings as they become fit, and keep them near the glass to insure sturdy growth, pinching out the growing point of those required for covering low trellises at the second rough leaf, others train with a single stem, securing to a small stick, rubbing off the laterals to the extent of the stem required to reach the trellis. Be sparing with moisture to plants in pits and frames, maintaining the temperature by linings renovated as required, closing early, and employing a covering over the lights on cold nights.

**PEACHES AND NECTARINES.**—**EARLY FORCED HOUSES.**—The leaves being off, or nearly so, complete rest should be aimed at by keeping the ventilators open constantly, and if the roof-lights be moveable they may be withdrawn for a time. This prevents undue excitement of the buds, and has an invigorating tendency, as the trees get thoroughly cleansed of dirt, red spider and thrips, and frosts prove destructive of brown scale, while the borders become thoroughly moistened by the autumn rains. If the roof lights cannot be removed see that there is no deficiency of water at the roots of the trees, for though the impression prevails that dryness at the roots accelerates ripening of the wood, it is fatal to the proper formation of the buds, and often gives them a check, causing them to fall later on. The soil should never be allowed to become dry at any time, but a much lessened supply of water will suffice when at rest than during growth. When the leaves have fallen the trees may be pruned. Only the strong growths that have not the points well matured need be cut back. In all cases be careful to shorten to a wood bud, not being deceived by a double or triple bud, as these are all sometimes blossom buds, especially on trees of a floriferous habit, induced through a somewhat stunted growth. Where ordinary attention has been given to disbudding, laying in no more wood than is necessary for the succeeding year's fruiting and for the extension of the trees, also removing fruited and other necessary parts after the fruit has been gathered, very little pruning will be required. Thoroughly cleanse the house, and if the trees have been infested with red or other insect pests dress them with an insecticide, as many, especially red spider, will secrete in the rough portions of the bark and on the woodwork, applying the dressings with a brush. If the trees have been badly infested repeat the application before they are secured to the trellis. Remove the mulching or loose surface soil, and supply fresh loam, having a handful of some approved fertiliser sprinkled over the surface. This will be washed in either by rains or watering, and sustain the trees at blossoming time and the early stages of the fruit swelling. Partial lifting of weakly trees will be necessary, and should be done before the leaves have fallen. In the case of trees that do not ripen wood well, the roots should be carefully lifted and relaid in fresh soil near the surface. If the drainage be defective it should be rectified, and where the trees are altogether unsatisfactory lift bodily and replant in properly prepared borders.

**SUCCESSIONAL HOUSES.**—In these, where the crops were ripened in June, the leaves will soon be cast, and the trees and houses should be treated similarly to those earliest forced. Trees that ripened their crops in July and August will now have the buds plumped, and the wood being ripe, the roof lights may, if moveable, be removed as soon as the leaves give indication of falling, or towards the close of the month. If the wood does not ripen well keep the house rather close by day when there is sun, and open the ventilators fully at night. Any weakly trees that do not plump the buds may be assisted with liquid manure. Trees from which the fruit has recently been gathered should not be neglected for removing the bearing wood of the current season, ventilating freely, watering inside borders, also outside ones as may be necessary, and occasionally syringing the trees and applying an insecticide, as insects must not be allowed to obtain and retain a hold on the trees.

**LATE HOUSES.**—Trees swelling their fruit will need the borders moist and mulched, and those with the roots in outside borders must not be neglected if dry weather prevail, and if carrying heavy crops liquid manure may be given until the fruit

commences to soften. When all the fruit has been gathered remove the shoots, not being extensions, that have carried the crop, and if the wood is not in a satisfactory condition as to ripening, gentle fire heat, with a circulation of air, will be advisable, especially in the case of late varieties. The midseason kinds will ripen the wood if the season be favourable, but if cold and wet the trees are benefited by gentle warmth and a free circulation of air. This is necessary in cold localities, especially with the very late varieties.

**STRAWBERRIES IN POTS.**—The plants from runners potted in July are making good progress, the earliest having the crowns sufficiently plumped for the detection of those that will not be available for early forcing. Those for this purpose should be separated from the rest and given sufficient space for the foliage in the most favourable position, such as a sunny sheltered one, for maturing the growths. The others also must have the pots wide enough apart to allow of the sun and air having free access to the foliage. The crowns in some cases are numerous, and should be reduced to the central one where large fruits are desired, not deferring it until they have attained to a considerable size, but be attended to as soon as they can be detected, and removed sideways with a bluntly pointed piece of hardwood stick. This will concentrate the vigour in the main crown, and will afford strong flower spikes, and then by selecting the largest and best formed flowers, and carefully fertilising them at the proper time, a crop of large shapely fruits will be insured. Any late runners may yet be potted, and with good attention they will be serviceable for late work in 5-inch pots, and may afford fine fruits and collectively as full a crop as those in larger pots. Worms and weeds are troublesome, also runners. Lime water will expel worms, and weeds and runners can be promptly removed.—**ST. ALBANS.**

### The Kitchen Garden.

**TOMATOES.**—Where it is necessary to move Tomato plants growing under glass by the end of the month, in order to make room for other plants, every endeavour must be made to colour the fruits as much as possible. If growing in pots they may be moved bodily to a warmer structure, and allowed to finish on the plants, gradually reducing the growth and shortening back the leaves. Less water will be required than when the plants were in full growth. Afford adequate moisture, however, to plants in structures where they are still in full growth and setting fruit. Fire heat and plenty of ventilation are both essential to Tomatoes under glass now. Young plants growing on for winter and early spring fruiting must have a position near the glass, as if the growth is otherwise than sturdy the plants will not be satisfactory. With regard to outdoor plants, further profitable extension of the growth is now out of the question, consequently it may be stopped, and any practical aid to furthering the ripening adopted. Fully expose the fruit to plenty of sun and light, and keep the plants dry. This may be effected by placing frame lights in front of the plants, so as to utilise and retain the heat longer than is possible without them. From time to time gather the forwardest and best coloured fruits.

**POTATOES.**—The digging of Potatoes may be general now, especially in view of the great probability of disease spreading owing to the protracted periods of wet weather experienced recently. It is not necessary that Potatoes remain in the ground until fully ripe and the shaws have died down. When the latter show indications of changing colour in the least the tubers may be removed as soon as convenient. It is a good plan to cut off the tops of each row before lifting, leaving enough stem to indicate the precise whereabouts of each root. Should the tops be tainted at all with disease burn them at once. Never allow them to lie about. In lifting spread the tubers on the surface of the soil, and remove immediately tubers touched with disease. It is not desirable to dig up more tubers than can be removed in one day unless the weather is exceptionally fine. Collect the various sizes into separate baskets, hampers, or bags, and convey them under cover. Spread in heaps on a dry floor, and exclude light with dry, clean straw or mats. The size of the heaps is immaterial so long as the Potatoes are stored dry. Should there not be sufficient room in shed, outhouse, or cellar under favourable conditions for keeping the tubers, the next best thing is to clamp them outside, forming fair sized ridges on well-drained ground, covering the tubers well with straw, over which lay a thick covering of soil. To allow of moisture escaping from the heap insert a narrow drain pipe, which may protrude above the covering of the pie.

**CABBAGES.**—The plants from sowings made several weeks ago ought now to be in admirable condition for final planting. The largest and strongest will, no doubt, be found amongst those which have been pricked out to strengthen those possessing good clusters of fibrous roots, but good plants may also be obtained from the seed beds, especially if thin sowing was the rule, or thinning of the seedlings early carried out. Plant moderately thickly in rows, which may be 2ft apart. The plants if placed a foot apart will allow of every other one being removed.

**CELERY.**—Considerable quantities of Celery well advanced in growth, which have been well fed and are thoroughly moist at the roots, may now be finally earthed. When the weather is dry and the plants are dry is the best time. To such rows preliminary earthings will have been given, hence there is nothing superfluous to remove. The leafstalks may, however, be gently drawn together and held loosely with strands of bass or raffia grass. This prevents soil reaching the hearts. Break the soil finely and work it round the plants with the hands, pressing firmly. Form slopes on each side rather steep, so as to drain away the moisture from the plants, an excess of which causes rapid decay at the centre.—EAST KENT.

\* \* All correspondence relating to editorial matters should be directed to "THE EDITOR," 12, Mitre Court Chambers, Fleet Street, London, E.C. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense.

### Plan of a Bothy—Competition.

"Well-wisher" promises a first prize of £3, and the Editor supplies a second prize of £1.

The rules of the competition are as follows:—The plan, drawn to scale, must not exceed 7in broad by 7in deep, and must be clearly defined on stout paper. The plan must provide suitable accommodation for six men, and the cost of the building ought not to exceed £200 to £220. A statement of the general items of cost should accompany the plans, together with any written comments thereon. The competition is open until Christmas, 1902, by which date all plans must be in the hands of the Editor. The sender's name and full address should be enclosed when sending the plan, and the sender will alone be held responsible for it.

**MAKING A LAWN ON SANDY SOIL—INOCULATING VERSUS SOWING** (Kittie).—We assume that the ground has been duly levelled and moved to an even depth, a fine and relatively firm surface secured. In that case the plot may be sown with grass seeds, the sooner the better, and a selection being made of species of grasses suitable for a sandy soil, this matter being named to the seedsman in ordering the mixture, there is no reason why as good or even better lawn should not result, as by inoculating or inserting pieces of turf about 3in square a foot distance apart over it and sowing between. By inoculating about 1-16th of the turf necessary for laying it down at once is required, and in order that the grass, mostly Perennial Rye Grass (*Lolium perenne*), may the more readily spread over the whole surface, the intervals between the inserted pieces should be raked, and not rolled or beaten until the patches meet, which they will likely do about midsummer. By sowing now the grasses would obtain a fair hold before winter, and even if lifted by frost they would roll down again and form a good lawn by the early part of the summer, not being cut too close or too early in the spring, but keeping well rolled.

**MELONS DISEASED** (F. G. D.).—The leaves are affected by Melon spot fungus, *Cercospora melonis*, which is very prevalent this season, not only on Melons, but on Cucumbers, market growers suffering very severely, the malady taking the shape of an epidemic and preventing full crops from being secured, indeed, not half a crop being secured on the second batch of plants, it not attacking the early ones, seldom appearing before the turn of the days after midsummer, when the night dews become heavier and the morning moisture is longer in being dispersed. The roots are quite sound, and though the stems give some indication when cut through of sleeping disease, we failed to discover any destruction of the vascular bundles or mycelia therein, and though the parts became slightly brown, as in attack by *Fusarium*, there was nothing of a determinate nature. The slight cankerous affection at the collar yielded the mycelial hyphæ of some fungus, but there was no connection between it and the vascular bundles, as is the case in attacks of *Fusarium* in the production of the early form, or *Diplocladium*. Probably more air and a drier atmosphere would arrest the fungus on the leaves, but this is so decisive as to prevent further progress in the plants and fruit.

**"BUSINESS ILLUSTRATED"** (Ever Anxious).—This publication is obtainable through the ordinary sources, i.e., the booksellers and newsagents. The address of the publishing office is 44-47, Bishopsgate Without, London, E.C. It is published every alternate month, price 1s. per copy, or free by post 1s. 4d. You would certainly find it interesting and useful.

**TOP-DRESSING CHRYSANTHEMUMS** (Cambridge).—You cannot do better than top-dress your plants at once, which will assist in keeping the roots active and supplying the plants with the necessary food to enable them to develop their flower buds. It is surprising what assistance a top-dressing of rich material proves to the plants in their latter stages, after the roots inside the pots have taken full possession of the whole of the soil. A system of top-dressing is practised by the majority of those who grow large flowers for exhibition. You will find equal parts of good fibry loam and cow manure with a little soot, say a 6in potful to half a bushel of soil, an excellent top-dressing for your plants, and the roots will not be long before they take possession of it. Some first-rate cultivators top-dress their plants with cow manure only, but we prefer the compost advised above.

**YOUNG VINES** (An Amateur).—It is difficult for us to say why the berries of your Grapes are small from the information supplied to us. The size both of the bunches and berries depends in a very large measure upon the growth the Vines made last year, and also upon the condition of the wood, whether thoroughly ripened or not. It is impossible to expect Vines with unripened wood that possesses neither strength nor vigour, whether young or old, to produce berries of a large size. Young Vines very frequently produce large-sized bunches, but the berries are often smaller than from vigorous Vines of a greater age. This is not always the case, for much can be done in swelling the berries to a large size by good cultivation, which under inferior treatment would only be small. The pruning would have nothing to do with the size of the berries. You cannot expect us to answer your other question about the soil, for you have not said one word whether you made special preparations for your Vines, or in what compost they are growing. If your letter had been less brief we might probably have given you a more useful answer.

**ROOT-PRUNING** (F. J.).—You had better not prune the trees till the crop is gathered, which you say will be in October. The remarks on root-pruning in September are, as you intimate, sound and clear, but they apply to fruitless trees of luxuriant growth. Yours, it appears, are not quite fruitless, yet are growing too freely, and you will not err by root-pruning in October, or immediately the fruit is gathered.

**NAMES OF PLANTS.**—Correspondents whose queries are unanswered in the present issue are respectfully requested to consult the following number. (T. J. R.).—Your number 6 specimen (second batch) last week should have been named *Juniperus virginiana* var., and not *Biota*. We require to see the cones for a nearer identification, (Mid-Sussex).—A splendid specimen of *Polygonum orientale*. (Frank).—*Ercilla* (*Bridgesia*) *spicata*, but a miserable specimen. (Able).—1. *Lonicera hirsuta*; 2. *Aster acris*; 3. *Deutzia crenata* fl.-pl.; 4. *Staphylea pinnata*. (F.).—*Solanum jasminoides*.

**Note to Readers.**—We request those of our readers who may experience any difficulty in obtaining copies of this Journal regularly to be good enough to acquaint us with the fact.

### Meteorological Observations at Chiswick.

Taken in the Royal Horticultural Society's Gardens at Chiswick, height above sea level 24 feet.

## Neglected Forage Plants.

Now that so much importance attaches to the rearing and fattening of cattle and sheep, it is the more necessary that no stone should be left unturned by the British farmer in his efforts to compete successfully with his foreign and colonial rivals. This has been a growing season; ample rains have flushed the pastures, and even made a dreadfully poor seed plant present a passable appearance. But how would it have been if the series of dry summers had not been broken, and this year been as dry as those which preceded it? It must have been most disastrous to breeders and feeders of live stock.

The Clover and Rye Grasses which form the stock in trade of the British flock-master cannot be depended on to grow, or even exist, under the dry conditions which may so readily recur. Last year the Clovers came up amongst the young Corn only to be dried up and perish before they got fair hold of the soil. This year there is an excellent young plant; but we shall not have a satisfactory return from it unless next summer we have sufficient rain.

There are, however, other plants which are so deep rooted that they successfully defy the severest drought, and if farmers would make freer use of these plants when making their seed mixtures they would not only grow heavier crops of forage, either for cutting or grazing, but be independent of the vagaries of British weather.

We have in mind four plants, but it is to three of them that we wish to draw particular attention. The fourth is Lucerne, and we have dealt especially with it on a previous occasion. Lucerne is, moreover, in our opinion, less suitable for mixture with other plants than the other three we shall name. It is more useful for small plots, where a certain quantity of green food is required for mowing every day for a lengthened period.

The first we mention is Chicory. This is a very deep rooting plant, and most remarkable for withstanding drought. It is more suitable for three or four years' ley than for shorter periods, as the roots are somewhat troublesome to eradicate. If sown by itself, 12lb to 16lb of seed per acre are required. The larger quantity on the drier soils. It grows well amongst Barley, Oats, or Wheat. It is too succulent to make hay of, but is splendid as a producer of green fodder.

The late Mr. Arthur Young, whose MSS. on the "Science and Practice of Agriculture" are now in the British Museum, was a great advocate of the cultivation of Chicory. He grew in four years 119 tons of green fodder per acre, or close upon 30 tons per acre per annum. At another time 62 tons of green produce was cut by him in one year. Chicory is readily eaten by horses, cattle, calves, and sheep. Very good cream and butter are produced from it. Mr. Young says in his book, "On all poor lands it is of the highest consequence, having no rival. On the very worst soils it is beneficial to sheep, and I may venture to assert that in such a full stock of sheep cannot be kept without it."

Chicory should be cut at rather short intervals, four times a year being better than three, which is the general practice with Lucerne. When it is desired to seed down poor sandy lands for a number of years, no mixture of seeds would be complete without a proportion of Chicory. It wears a long time, a good quantity having been found ten years after it was sown.

The next plant is Burnet. This also is a deep rooting, drought resisting plant, though Chicory is said to be superior in that respect. It is not suitable for mowing, as cattle do not eat it well when it is in bent. It is most useful to form part of the mixture for sheep pasture on dry sandy soils, which are most favourable to its growth. When sown by itself, 20lb to 30lb per acre, broadcast, would be needed; but 6lb to 8lb per acre, with other seeds, we should prefer.

When sown in a mixture, sheep eat it down closely, and thrive well on it. It grows early, and is ready for grazing by the beginning of March, which is an important advantage to sheep breeders, as it provides fresh food when it is most urgently required. Burnet is a most healthy food for sheep, and has the excellent quality of correcting scour. As we have said, it is not so suitable for hay as some other plants; but a portion of Burnet amongst hay will prevent the latter from over-heating.

Another little known, but very valuable, plant is the Kidney Vetch. A few years ago Mr. Hunter Pringle called attention to the great value of this plant as grown on the poor sands of Norfolk and Suffolk. Personal experience confirmed the correctness of Mr. Pringle's statements. It will flourish where Clover can hardly exist. We have grazed it and made hay of it, but should recommend it as a companion to Burnet for sheep pasturage. It will stand for years if the winters be mild; but 30deg of frost will kill off old plants. Young plants will stand frost well. Twenty pounds per acre is the proper quantity to sow alone; but, as with Chicory and Burnet, we should recommend a mixture.

For a five or six years' ley on thin or sandy soil, 4lb White Clover, 8lb Burnet, 6lb Chicory, 8lb Kidney Vetch, 4lb Rib Grass, and the Rye Grass which does best in the soil (say 7lb of it), would make an excellent mixture, and could be relied on to keep growing and provide a good bite when ordinary everyday mixtures would be dried up and dead.

### Work on the Home Farm.

Grass land farmers have gone through very sad experiences during the last year or two, but they are getting their own again now. They rejoice in full pastures and good markets for their fat stock, and at the same time see their arable brethren wallowing in a slough of despond produced by a succession of showers just when sunshine is the only thing desired. After two seasons of too much sunshine and too little moisture, it is very disheartening to farmers to find themselves hampered by the opposite extreme, but so it is, and we have to make the best of it.

To-day we have a tearing wind, and as only a small portion of the Corn is in stook, we are naturally fearful as to its effects on the standing crops. Barleys of the Standwell and Goldthorpe type are very largely grown, and being very liable to neck in a wind, a gale like this may cause heavy loss. The best ears of Barley we have seen this year are Wrench's Prolific, a variety of Chevalier with both length of ear and plumpness of grain. The grains near the tip of the ear are as big as those in the middle, a most desirable feature.

Reapers are working well considering the difficulties they have to contend with. Wheat is easy enough to do, but some of the Barley which became lodged in June is so rotten that it is pulled up by the fingers before the knife has a chance to do its work. The best way is to put men to work with scythes and mow out all the bad bits. If this rubbishy stuff is tied up at once and stooked by itself it may be kept apart altogether from the better portion of the crop, with great benefit to the latter.

Barley is cutting and stooking up well, and the samples will be of good size, though they are considerably stained. Oats are disappointing. In the majority of cases their appearance in stook compares badly with their appearance uncut. Samples will be good and heavy. With fine weather new Oats will soon be on the market. Prices are tempting, and farmers want money. They also want thatch, so it is likely that heavy thrashings of Wheat will take place shortly.

It is a long time since farm live stock showed such a clean bill of health. The loss of lambs has been of the smallest proportions, and these animals are, in point of growth and condition, far above the average. Plenty of food accounts for good condition, and good condition is the best safeguard from disease. Sheep will have to go on Turnips shortly, but it will be convenient to get the harvest in first. There will be plenty of young Clover in the stubble, but Turnips are so good that we shall hardly require to graze new seeds this autumn. They will be better for being untouched until spring.

Milk cows have enjoyed such good pasture that they have kept up the milk supply in very unusual fashion. That the quality has not kept pace with the quantity is proved by the numerous prosecutions of dairy farmers for selling weak milk. Cows will pay as well for cake when pastures are good as when they are sparse. Though there is still plenty of grass, it cannot be of summer quality, and cotton cake must be allowed. Foals must soon be weaned, especially if the mares are required for harvest work. Unweaned foals are often thrown amiss when their dams are working. Reaping should especially be avoided. For early lambs the ram should now be with the ewes. There is increasing tendency to use black-faced sires, and with the wool trade in its present state no sensible man would do otherwise.

## Australian Grazing Lands and Grasses.

The excellent character of Australian dairy and other food produce generally, is largely due to the rich character of the greater portion of the grazing lands, especially in the vicinity of the sea coast, where the rainfall is most frequent and copious. In New South Wales, the Illawarra district, famous for its cheese and butter, possesses some of the best pasturage in the Commonwealth, consisting of different kinds of herbage in varying proportions. In newly laid down pastures, says an agricultural expert, Perennial Rye predominates, but the reason is that a greater percentage of seeds of this Grass is generally sown in mixture for permanent pasture. Cocksfoot form a fair percentage of the permanent herbage, and appears to withstand dry weather better than Rye. White Clover is also abundant, more particularly in pastures which have been laid down a few years. Under ordinary conditions it produces an abundance of seed, and when the autumn rains set in they readily germinate. During the spring months, should rain fall at frequent intervals, the Clover grows rank, and when cows eat ravenously of it very frequently produces hoven. With this exception, the Illawarra dairymen look upon it as a valuable pasture plant.

Prairie Grass is conspicuous in most pastures, the rich, succulent herbage being much relished by stock. Rib-Grass is plentiful, and is regarded as an excellent food for cows, and as increasing the flow of milk in dairy cattle that eat it. Among the useless Grasses, from a dairyman's point of view, is the "meadow soft grass," or "Yorkshire fog," said to have been introduced with Cocksfoot seed into New Zealand. In both new and old pastures, but especially the latter, there is a considerable percentage of indigenous grasses and plants, and in dry seasons these, more particularly the Couch Grass, often prove the mainstay of the pastures, the native grasses being enabled to withstand the effects of drought for a longer period than are the artificially-sown grasses.

In the New England district of New South Wales some of the grazing lands are among the finest known, and during the summer months are unsurpassed for the rich, succulent, and varied character of the indigenous grasses and forage plants which clothe them. One of the most common "grasses" is the "Wild Sorghum," which is highly spoken of. Not only are sheep and cattle, we are told, fond of the herbage, but it is said that horses eat the seed heads and fatten on them. "Kangaroo Grass" is plentiful, and grows to a great height when left unmolested. "Wallaby Grass" is common in places, and has a high reputation as a forage plant, by reason of its drought-resisting properties. The "blue grass" is also a valuable herbage plant. The herbage likewise includes the "tussack poa," "star" or "windmill grass," and "wheat grass."

The "Bent Grasses" are common; although only annual grasses, they yield rich, succulent herbage during the early summer months, when most other grasses are in the earlier stages of growth. The "long hair Plume Grass," when in flower, is a conspicuous plant on pastures. On the banks of some creeks and in low damp places the "water Couch Grass" is plentiful. It is a quick grower, and greedily eaten by cattle. There are numerous other native grasses which afford excellent food for live stock.

Among the exotic grasses the white Clover is, perhaps, the most abundant, growing more freely than in colder countries, the New England pastures in spring being literally white with its flowers. In the Camden district, near Sydney, when first settled, the tall, waving "Kangaroo Grass" was so plentiful that when in seed the country resembled an immense Wheat field. The grasses are much the same as in the New England district. Noxious weeds and supposed poisonous plants are found on many of the Australian grazing lands, but in most places are kept in check by stock owners.

The commonest weeds are a couple of so-called Dandelions, which, although not productive of ill-effects in live stock, naturally tend to diminish the quantity of useful herbage by choking out the nutritious grasses. At one time the "Cape Weed" threatened to become a destructive pest, but it is being kept within bounds, as are the Thistles and Dock plants.

The rapidly increasing importance of the Australian dairying industry has occasioned greater attention being given to the maintenance and improvement of the pasture lands generally, with the result that their feeding and fattening capabilities have become largely extended. The growth of the more useful indigenous grasses is encouraged, and where artificial sowing is necessary the best kinds of grass seed from Europe and America alone are used. Considerable quantities of grass seed, both indigenous and exotic, are also obtained within the Commonwealth.—JOHN PLUMMER, Sydney.

# BARR'S GOLD MEDAL DAFFODILS

The Most Lovely of all Spring Flowers.

Have received Twelve Highest Awards, 1902, including TWO GOLD MEDALS.

## SPECIAL OFFER OF TEN GRAND DAFFODILS

Strongly recommended for filling Flower Beds and for Pot Culture, also to grow for Cut Bloom, or to naturalise.

OF the following Ten Handsome Daffodils we have cultivated large stocks, knowing how highly they would be appreciated by amateurs when obtainable at a price which will allow of their being planted in quantity. All are strong growers and free bloomers, bearing showy and beautiful flowers with long stems, and will be found of great value to cut for Vases and Church Decoration, &c. Per 1000. 100. doz

**BARRI CONSPICUUS**, a flower of great beauty and refinement, having broad soft yellow petals and short cup, with deep margin of orange-scarlet; its lovely flowers are much prized for vases, bouquets, and buttonholes. Strong Flowering Bulbs .. 50/- 5/6 -/10  
Extra Strong Selected Bulbs 70/- 7/6 1/3

**BEAUTY**, one of the finest coloured Chalice-cupped Daffodils, bearing bold handsome flowers on long stems; large yellow perianth; cup large and handsome, yellow stained orange-red; valuable for cutting and exhibition, remarkably effective. Extra Strong Selected Bulbs — 25/- 3/6

**DUCHESS OF WESTMINSTER**, an exquisite flower, and one of the best of the Leedsii section; perianth clear silvery white, and cup opening a delicate primrose, flushed rose, but passing off white. Extra Strong Selected Bulbs — 53/- 7/6

**EMPEROR**, a grand Trumpet Daffodil, well deserving its name Emperor, on account of its very large, rich, full yellow flowers and stately bearing, very free blooming; prized for cutting. Strong Flowering Bulbs .. 45/- 10/6 1/6  
Extra Large Bulbs .. 120/- 13/6 1/10

**EMPRESS**, a charming companion plant to Emperor; the flowers are large, chaste, and beautiful, and of great substance, with rich golden-yellow trumpet and bold snowy white perianth. Strong Flowering Bulbs .. 110/- 12/6 1/9  
Extra Large Bulbs .. 140/- 15/- 2/3

**GRAND DUCHESS**, a very beautiful early-flowering Leedsii, with elegant silvery white flowers, having cup stained apricot-orange; greatly prized for cutting. Extra Strong Bulbs .. 45/- 6/-

**GRANDIS**, a very handsome late Trumpet Daffodil, with large bold flowers; petals snowy white, large, and broad, and of great substance; trumpet large and full yellow; it blooms when all other Bicolors are over, is an ideal bedder, and its noble flowers for cutting are greatly appreciated. Strong Flowering Bulbs .. 95/- 10/6 1/6  
Extra Large Bulbs .. 120/- 13/6 1/10

**MRS. LANGTRY**, a dainty silvery Chalice-cupped Daffodil of the Leedsii group, having the white cup elegantly margined golden yellow, a characteristic and novel as it is beautiful; one of the freest bloomers and a favorite for bouquets, buttonholes, and vases. Strong Flowering Bulbs .. 145/- 13/- 2/3  
Extra Strong Bulbs .. 200/- 21/- 3/-

**QUEEN OF SPAIN**. This lovely Daffodil might fitly be called the Queen of Trumpet Daffodils. The flowers are of a uniform soft delicate yellow, with very elegant trumpet slightly expanded at mouth, and the perianth flying back; as a cut bloom it is a gem, while no Daffodil is more beautiful naturalised in grass; it lasts longer in bloom than any other Daffodil. Good Flowering Bulbs .. 135/- 14/6 2/-  
Extra Strong Bulbs .. 17/6 2/6

**SIR WATKIN**, the Giant of the Chalice Cups, a bold, handsome, rich yellow flower with large open cup sometimes stained orange; a strong sturdy grower and free bloomer; for cutting, its showy flowers are greatly prized, while for bedding, massing and naturalising in grass, &c., it has few equals. Strong Flowering Bulbs .. 95/- 10/6 1/6  
Extra Large Bulbs .. 120/- 13/6 1/10

Barr's Daffodil Catalogue (Free) contains a full Descriptive List of all the finest Daffodils in cultivation, including the latest Novelties of 1902.

**BARR & SONS,**

41, 42, & 1 3, KING STREET, COVENT GARDEN, LONDON

No. 1160.—VOL. XLV.—THIRD SERIES.

## BEAUTIFUL FLOWERS

IN WINTER AND SPRING.

# WEBBS' POPULAR COLLECTIONS OF BULBS.

TO SUIT

ALL REQUIREMENTS.

The Finest Selection from the best Bulb Farms of Holland.

**COLLECTIONS for BEDS & BORDERS**

From 5/- to 105/- each.

**COLLECTIONS for POTS & GLASSES**

From 10/6 to 105/- each.

**COLLECTIONS for the GREENHOUSE**

From 5/- to 42/- each.

## HARDY BULBS

**COLLECTION "F" FOR SPRING GARDENING**  
Contains 1002 Bulbs.

|                                |                                   |
|--------------------------------|-----------------------------------|
| 48 Hyacinths, distinct colours | 300 Crocus, in 4 distinct colours |
| 40 Tulips, single early        | 100 French Ranunculus             |
| 50 " double                    | 50 Snowdrops, single              |
| 25 " single late               | 75 Spanish Iris                   |
| 20 Narcissus Polyanthus        | 18 Scilla Sibirica (Præcox)       |
| 30 " incomparable              | 4 Liliun Umbellatum               |
| 24 " Poeticus                  | 50 Eranthis Hyemalis              |
| 24 Anemones, double            | (Winter Aconite)                  |
| 50 " single                    | 24 Ixiis, best mixed              |
| 26 Gladiolus Naxos             | 24 Tritoleia uniflora             |

**COLLECTION "C" FOR INDOOR**  
Contains 335 Choice Bulbs for 72 Pots and Glasses.

HALF OF EITHER OF THE ABOVE FOR 11/-.

The above Packages may be had from our AGENTS,

**Messrs. MERTENS & CO.,**

3, CROSS LANE, LONDON, E.C.,

On receipt of Cheque or Post Office Order.

Our Descriptive BULB CATALOGUE (100 pages, in English), containing FULL CULTURAL DIRECTIONS, will be sent post free on application to our Agents as above, or ourselves direct at

**OVERVEEN, HAARLEM, HOLLAND.**

## Journal of Horticulture.

THURSDAY, SEPTEMBER 18, 1902.

### The "Home" Bulb.

THE greatly increased number of bulbous plants now used, I shall not say cultivated, in gardens, for in most cases they are purchased ready to produce flowers, makes it a matter of some importance to know where to go for bulbs. Holland, for centuries, has enjoyed the pleasure and profit of supplying Great Britain with her bulbs, not because they could not be as well produced on this side of the sea, as because it has hardly ever occurred to anyone to give the same attention to their wants as have the Dutch. No one thinks now of going to Holland or France for fruit trees; yet, at one period, these two countries possessed a settled trade in young trees. Nor do we send to the Continent for our highest class seeds, knowing that our own seed growers possess superior strains. The sole reason why British-grown fruit trees and seeds are better than those we can purchase on the Continent, is to be found in the greater care taken in the production of each, and we willingly conclude to pay a largely enhanced price for the superior article.

So prejudiced, however, has been the feeling in favour of Continental bulbs, that, if not at the present time, or certainly not many years ago, market growers were accustomed to send their forced bulbs to be grown on in Holland, till they had recovered strength to flower again as well as previously. At present, enormous quantities, particularly of Daffodils, are cultivated even in Scotland, and, after three or four years growing in fields, are again ready for forcing. I have pursued a like practice during many years, and stock of some sorts has increased to such an extent, that enormous quantities of the more prolific sorts have been, from time to time, thrown out for want of room, and the

READERS are requested to send notices of Gardening Appointments or Notes of Horticultural Interest, intimations of Meetings, Queries, and all Articles for Publication, officially to "THE EDITOR," at 12, Mitre Court Chambers, Fleet Street, London, E.C., and to no other person and to no other address.

better kinds have been employed without a shadow of expense in planting up grassy glades.

I have never attempted the production of Tulips for forcing, but a gardening friend whose soil suited Tulips to perfection, forced home-grown bulbs during many years, and with great success. Forced Hyacinths, too, after gaining strength, though as good spikes as the generality one purchases, and much superior to the cheap bulbs so common wherever one goes. I might proceed to show that Spanish and English Irises from seeds are as easily produced as Potatoes, and the same with most other hardy bulbs, but I do not wish to indulge in too many subjects at one time. The question that more particularly engages my attention is how results such as I have hinted at can be secured. The answer is a very simple one. Merely to cultivate them with as much care as we give to any other subject we decide to succeed with. I have seen potfuls of forced bulbs huddled together into the ground, one potful close to another. It is plain, treatment of that nature is not of a kind to produce superior bulbs. Rather they must decrease in vigour, and end in complete failure. But, on the other hand, plant in good soil thoroughly cultivated, allowing each bulb sufficient space for the development of its foliage and its progeny for the next three years, not forgetting each spring to apply something extra—soot, rich soil, rotted muck, or mineral manures, and with the ordinary attention due to all crops, the result will be bulbs to be proud of, and flowers a joy and source of rejoicing.

There is still a wider phase of this question, that it may be not amiss to touch on just at present. That is, whether home growers for sale are competent to produce as satisfactory bulbs as the foreigners. I think there is no question but that they are. Continental bulbs may have the advantage in forcing more easily, but in other respects they have none that cannot be equalled by the home production. New Daffodils alone will form a big trade in the future, and it has been shown in the case of home-grown bulbs of new varieties that these are equal to those of Continental growth. Nothing could be better, for instance, than the behaviour of the Engleheart varieties distributed last year. Novelties derived direct from the Continent, as well as others in commerce, were not of finer quality.

But if the home grower is to keep up his sales, he must also keep up the quality of his bulbs. I saw an instance last spring of a piece of wild gardening absolutely spoilt by the inferior quality of bulbs, of which, I am sure, not over 5 per cent. produced a single bloom, while Continental stuff bought at the same price yielded on an average about 250 blooms to a hundred bulbs. Policy of this kind is bad, not only for the party interested, but it cannot miss injuring trade growers as a whole. The same unhappy way of conducting business has occurred in the case of home-grown bulbs of Fritillarias, Scillas, bulbous Irises, &c., which, had to be cultivated a year before they were sufficiently strong to bloom. Whether it is a desire to keep the best bulbs for growing in his own grounds that induces a tradesman to send out an inferior article I cannot say, but to compete with the foreigner at equal prices the best must be sold and the less good grown at home. The question during late years has assumed dimensions of some importance, and I am acquainted with many workingmen amateurs, and those higher in the social scale, who annually make bulb purchases directly from the Continent, and they have no interest except they believe they get thence the better article, for, at the same time, flower and vegetable seeds are purchased, regardless of price, so long as they are assured of their high quality, from home seedsmen.—R. P. BROTHERSTON.

### IRIS BUCKARICA.

A new species named and described by Sir Michael Foster, F.R.S., and native of Eastern Bokhara, on mountain slopes at an altitude of 5,000 to 6,000ft, and on the sides of river Sureh-ab, a tributary of the Amu Darya. It was discovered by a collector of the firm of Messrs. Van Tubergen. Miss Willmott, of Warley Place, Great Warley, exhibited a specimen before the Floral Committee of the Royal Horticultural Society on the 8th of April last, and was accorded a First Class Certificate. *Iris Buckarica* resembles *I. orchoides* in many respects, the points of difference being in the flower. It has fleshy stems, and the shining, linear, succulent foliage is luxuriant below the terminal flowers. The recurving tips of the blades are deep sulphury yellow, the petaloid stigmas and the claw being white and conspicuous. The "standards" are reduced to mere flimsy bracts. Its culture, no

doubt, is identical with that of other bulbous Irises. Irises succeed in sandy loams, well enriched, and in sunny, sheltered positions. They are also grown in pans for spring flowering. The illustration on page 261 is from a drawing by Mr. Geo. Shayler.

### New Daffodils.

Scarcely has the foliage of the Daffodil disappeared when new catalogues arrive, raising hopes and exciting desires that must perforce remain unsatisfied. Many exquisite varieties, however, can now be obtained at a small outlay. The newer sorts are beyond the reach of ordinary means. "Many men, many minds," may be rendered, and we may say, "Many men, many floral tastes." The Daffodil, with its beautiful form and robe of golden sheen or virginal purity, cannot but be a general favourite. So, when one was told by a veteran florist in the foremost files of the day that he hated Daffodils, the expression was assigned its true value. No doubt the modest *Auricula* has insinuated herself into the sanctum of his affections, and the gaudier *Carnation* and winning *Picotee* guard the inner court, but in the outer there is room for every flower that blooms. The sweet *Auricula* appeals to the taste of comparatively few, and to many who attempt its culture the *Carnation* in its finer forms is a lovely nuisance. But, as the French have it—*chaque à son goût*—each one to his taste.

The past season was a record one for the Daffodil. The development was slow, never were the flowers larger or of better quality, and the period of bloom was unusually prolonged. Emperor was uncommonly good, nearly one-third larger than usual, and of exquisite finish; M. J. Berkeley and Maximus in extra intensity of colour; Grandis of perfect purity; and Mrs. Camm rivalled Madame de Graaff in all but form. So one might maunder through his moderate collection in the fond delusion that what gave him so much pleasure must necessarily be of interest to others. To the writer, the event of the season was the annual visit to Valleyfield, Penicuik. To Mr. Cowan the ordinary Daffodil lover in Scotland is indebted for a feast he could not otherwise enjoy. Prompt to the eagerly-awaited intimation that the Daffs were on at Valleyfield, a trio of friends were on the spot. In addition to a cordial greeting from Mr. Cowan they were saluted by a great fanfare of golden trumpets, and thousands of fair heads nodded welcome. There is no need to refer to this great general collection. All varieties were there that are worth growing.

The prominent new sorts may be glanced at, these including a large number of the Rev. Mr. Engleheart's seedlings. Leading the way at the head of the big battalions came Lord Roberts, a striking Daffodil worthy of its illustrious name, with fine stiff, massive, golden perianth, and great frilled trumpet. Catalogued at £21 it is, and likely will long continue to be a flower for the privileged few. Golden Bell is well named, the large trumpet seeming almost luminous; Siren, a pretty flower with long white trumpet; Florence, a fine white, and Galatea, a smaller refined white trumpet, were specially noticeable. Among the cupped varieties of high merit were Ariadne, with spreading cup, very slightly tinged with lemon; Waterwitch, a fine white bloom like an improved Beatrice; and Torch, whose bright orange and scarlet cup is very attractive. As on former visits, the Goliaths of the race were interviewed—Monarch, Shakespeare, Weardale Perfection, Duke of Bedford, and others. Queen Wilhelmina and Hodsock's Pride were not then quite expanded.

A supplement to these was presented at the subsequent spring show in Edinburgh, where a table of Daffodils from Valleyfield formed a supreme attraction. Among others, one there noted Sol, a great yellow trumpet; Maggie May, a very beautiful Leeds, with pure white perianth and pale citron cup nicely frilled; and King Alfred a golden self trumpet, if not the largest, in refinement of colour and perfection of symmetry peerless among Daffodils. Lovers of this flower are grateful to Mr. Cowan for an opportunity of seeing these and such rare varieties.

The removal of this great collection to new quarters where they will be free from the polluting breath of well-known extensive works, must entail immense labour on Mr. Pirie, Mr. Cowan's able gardener, but will result in enhanced pleasure to its owner in the unsullied purity of his favourite flower.—A NORTHERN AMATEUR.

## Commercial Bulb Culture.

The development of commercial bulb culture in the United Kingdom has received an enormous impetus during the past forty years, and especially during the last half of that period. During the first decade of the last half of the last century bulb culture was carried on in this country on a very restricted scale. Lincolnshire and Cambridgeshire supplied large quantities of yellow Crocuses and double Snowdrops. Many of the Surrey, Middlesex, and Kent market gardeners, who grew the common double Daffodil for bunching for market, would dispose of their surplus bulbs to some of the London wholesale seed houses. Ixias and Sparaxes were obtained from Guernsey, but the great bulk of the bulbs sold in this country were obtained from Holland, France, and elsewhere.

Since then a huge industry in the form of bulb culture has grown up in this country, consequent upon the popularising of the Daffodil. A very important step in this direction was taken when, some thirty years or so ago, Mr. J. G. Baker classified the then existing varieties of Daffodils by dividing them into three main sections—the magni-coronati, the medio-coronati, and the parvi-coronati. Mr. Barr was exhibiting the best varieties then in cultivation, and chief among the first-named section were Emperor, Empress, and Horsfieldi. He also hunted up hitherto unknown varieties. He fired many with a desire to cultivate, and some he prevailed upon to attempt the task of adding to the then known varieties by means of cross-fertilisation. On May 2, 1877, Mr. Peter Barr exhibited at an exhibition held by the Royal Horticultural Society at South Kensington (which her late Majesty Queen Victoria opened) a collection of Daffodils, to which the Large Silver Gilt medal of the Society was awarded. This venture had the effect of drawing public attention to the beauty of the flower, and some far-seeing men to its value for commercial purposes. One result was to enhance the usefulness of the Daffodil for decorative purposes, and the acknowledged utility of the flower in this direction induced many to cultivate for this purpose, and also to supply bulbs for sale in a dry state.

The huge industry which has sprung up in the Scilly Islands is well known, and in spring tons upon tons of cut blooms are sent from thence to London and other parts, which become distributed throughout the country. From the South of France and along the shores of the Mediterranean, and from other sources abroad, come enormous quantities of bloom, and of some varieties which cannot be so successfully cultivated in the more temperate climate of the United Kingdom.

Bulb farms, some of them on an extensive scale, have been formed in different parts of the country, at Spalding in Lincolnshire, and at Wisbech in Cambridgeshire, in particular. I am by no means to be understood as stating that

these two counties have a monopoly of Daffodil culture, but Spalding has certainly become a great centre of the bulb industry. The Daffodil appears to be more suited to our English soil than any other popular spring flowering bulb, as it will do well in any good loam, even if somewhat heavy.

The Hyacinth, the Tulip, with the Crocus, needs, in order to bring the bulbs to perfection, a lighter and more sandy soil than the Daffodil, and that is the main reason why we depend so much upon Holland for a supply of these subjects, but look at home for our Daffodils. In Ireland, on the sandy shores of the Bay of Dublin, and elsewhere, Messrs. Hogg and Robertson cultivate Tulips with great success, as shown by a field of their Keizerskroon on

page 268. At Cork Mr. W. Baylor Hartland grows Daffodils to a considerable extent, while at Lismore, Co. Cork, on the banks of the Blackwater, Miss F. Curry has built up an interesting Daffodil industry, and furnishes to Daffodil exhibitions flowers of very fine quality. If the cultivation of the Hyacinth, the Tulip, and the Crocus is to become a national industry, then I think Ireland may furnish the most suitable localities for its prosecution.

At Spalding and Wisbech in particular the Daffodil, as already stated, is most extensively cultivated, and it is possible to see in the season beds of two hundred and three hundred thousand of a single variety. Those who send cut flowers to market gather them when a little more than half open; they are then taken into a house heated at a high temperature, in which the flowers become fully expanded while perfectly pure, which they would not be if fully exposed to the elements in the open. They are then removed to the open air and stood in vessels of water to stiffen the petals, and the blooms are then bunched and packed for market. There may be modifications of this practice as a result of the teaching of experience, but generally the procedure followed is that set forth. The flowering bulbs are lifted in July, or as soon as ready, sorted, and stored for sale. The strong bulbs are planted in September, or about that time, in well prepared beds; the offsets planted in nursery beds, where they remain for two or three years, until they have grown into flowering size.

(See Messrs. Bath's illustration on page 275.)

Those who grow for cut bloom find certain varieties best suited for the purpose, and grow them, as already indicated, in large quantities. But such find it necessary to add new varieties to their lists from time to time. Those who cultivate bulbs for sale must, of course, keep their collections up to date by adding expensive varieties, in order to be able to compete at Daffodil exhibitions, or exhibit collections of the leading varieties, as well as supply orders when sufficient stock is available. New varieties come from distinct crosses. The Rev. G. H. Engleheart is the premier raiser of the day. Some are imported; others are found in gardens, and of late years collections have had important additions made to them from such sources.

Time was when the Anemone and the Ranunculus, though

**Iris Buckarica.**

(See page 260.)

not strictly bulbous plants, and the Winter Aconite also, were largely grown in this country. We have recently turned our attention to Ireland, and found there the finest strains of Anemones. The Ranunculus, practically a neglected plant, is now but little grown. We import Ixias and Sparaxes from Guernsey and a few other subjects, which are grown only to a limited extent. The Roman Hyacinth comes from abroad; so do the early Gladioli. But the Daffodil is now essentially an English flower, and there is every probability that the bulb industry of our own country, and especially so far as it relates to the Daffodil, will grow rather than diminish in the years to come.—  
RICHARD DEAN, V.M.H.

*Galtonia candicans.*

## GALTONIA CANDICANS.

This stately compeer and meet associate for scarlet Gladioli in beds or borders, will be known to some of our readers as *Hyacinthus candicans*. It is a splendid bulbous plant, and one which has for many years been employed in larger beds, these containing Gladioli, as we say, and Kniphofias and similar flowers. It flowers during July, August and September, the beautiful, scented, drooping white flowers shooting erectly to 4ft high. The illustration, kindly lent by Messrs. Dicksons, Ltd., Chester, affords an accurate impression of its character. The bulbs are as easy to cultivate as either Hyacinths or Kniphofias; indeed, what suits these, will also answer for Galtonia. The plants are easily increased by detaching the offsets from the bulbs in September or October, and replanting.

## The Forms of the Narcissus.

It is a common circumstance that all novelties, the result of the hybridist, must show changes of form, perhaps in one distinct line, perhaps in many, as in the present instance, so that either as natural hybrids picked up by the explorer after rarities, or the production of the stay-at-home manipulator, there is now a wonderful diversity of form among Narcissi. Form, indeed, has for some years appreciably marked the status of many sorts.

The true Narcissus or Daffodil of old England was undoubtedly *N. poeticus*, to which the name of *parvi-coronatus* has been given in Mr. Baker's monograph of 1869. This section is not represented in any of the cuts on the opposite page, but is well known by its flattened white petals and its tiny cup. The finest forms at present in commerce comprise *ernatus* and *recurvus*, the old-fashioned Pheasant's Eye. Both sorts require high culture. It is deliciously scented. *Grandiflorus* and *Almira* are newer sorts, the last-named the more promising of the two. The double poeticus derived from Constantinople three centuries ago is, when in good form, exactly like the top bloom of Golden Phoenix (see figure). It was asserted and finally proved by Mr. Barr to be a form of *patellaris*. It, like the others, affects high culture. It has been named the *Gardenia Narcissus*, but the old English name, Sweet Nancy, is much prettier.

In the same group is *N. biflorus*, a supposed natural hybrid between a poeticus and *N. polyanthus* or a Tazetta. The bloom is primrose coloured and inexpressibly sweet. *N. Tazetta*, also derived from Constantinople, is best known as the species that provides the charming *Soleil d'Or*, *Grand Monarque*, &c., the lovely Paper White and The Pearl, which, I believe, was long grown on the Scilly Islands as the Scilly White.

The *Burbidgei* section is the result of a cross between *N. poeticus* and *N. incomparabilis*. There is not a cut of this either, but the flowers are round, rather small, with the perianth either white or yellow, and the cup small, varied in colour. The one I like best is *Vairessa*, but *Bareness Heath* and *John Bain* may also be grown. They are capital for cutting. I have purposely referred to these first, because amongst them we have the oldest, the prettiest, the sweetest, and the easiest cultivated forms.

The *Magni-Coronati* section, of which the English Daffodil is the commonest, contains the most magnificent forms. They are the old Bastard Daffodils or pseudo-Narcissi. Henry Irving comes very near the type, but with the trumpet enlarged. In many places the true pseudo fails to bloom satisfactorily, but generally *N. obvallaris* succeeds, *Golden Spur*, *Glory of Leiden*, *Shakespeare*, *Emperor*, *Maximus* (see plate), *I. B. Berkeley*, and *Prince Alfred*, are each excellent. Of the lovely bicolor forms the more desirable are *Horsfieldi*, *Grandee*, *Weardale Perfection*. Among the wholly white or sulphur tinted varieties, *N. Albicans*, *Mrs. Thomson*, and *Madame de Graaff* should be certainly grown, *Pallidus præcox* where it will grow, and *Princess Ida*, a most charming variety, and good doer.

*N. Johnstoni* Queen of Spain belongs to this section, and *Santa Maria* a very early kind. The *Swan Neck* or *W. Goldring* has drooping flowers of much the same form. Then there are *Minimus*, *Minor*, and *Nanus*, all three dwarfs. Double forms of this group, *Telamonius plenus*, and *Capax plenus*.

The group between the last and the first is called *Medio-coronati*, and is remarkable for the large number of hybrid forms of which it is mainly composed. Of these the most beautiful is certainly the *Incomparabilis* section, and of these the finest is *Sir Watkin*, a variety with a queer modern history, but an old English flower, supposed to be the "Great Nonpareille" of Parkinson. *White Queen* is an expensive pure white, reckoned by connoisseurs the finest of this type, and *Brigadier* and *Lady Margaret Bescaven* are other grand forms. *Gloria Mundi*, *Stella Superba*, *C. I. Blackhouse*, *Queen Sophia*, *Red Star*, and *Lulworth Beauty* also deserve special notice.

There are three double forms in this section, of which the most beautiful is *Sulphur Crown*. The plant is too tender to do well except in a warm position. *Codlins and Cream* is the quaint common name of this form.

Of the *Leedsii* section are a few that cannot be denied a place in the most contracted of gardens. Such a one is *Mrs. Langtry*, here portrayed. In every respect it is exquisite. Some people, however, prefer *Minnie Hume*, and *Duchess of Westminster* ought to be added. Some of the *Barri* section are almost equally charming, especially *Barri conspicuus*, *Flora Wilson*, the *New Sea Gull*, and *Albatross*. In addition I would crave a little room to draw attention to the little Rush Daffodil, *N. Jenquilla*, the *Campernelle Jonquil*, *N. odoratus*.

The forms of *N. triandrus* are of exquisite beauty, and *N. cyclamineus* should certainly find a place on account of the recurved flowers.

I have to apologise for neglecting *Nelsoni Major*, the best of a section so called after an old raiser of Daffodils. The *Hoop Petticoat* (*N. Bulbocodium*), and some others do not succeed in the open, but they are certainly worth the trouble of growing in pots, planting the bulbs quite close together.—R.

### FORMS OF THE NARCISSUS.

*These illustrations and the accompanying article are intended to attract attention to the classification of the forms of flowers in this genus, but a scientific, systematic treatment being undesirable here, the matter is presented in readable form. Messrs. Sutton's illustrations on this page are referred to in the article by "R.," who separately deals with the three main Groups (1, magni-; 2, medio-; and 3, parvi-coronati) of the Narcissus, and the sub-groups Barri, Leedsii, Burbidgei, &c. Useful up-to-date guides on this subject are some of the Daffodil catalogues.*

## Naturalising Bulbs in Grass.

Year by year the practice of planting bulbs in grass finds more favour with plant lovers, and at the present time vast quantities of bulbs are used for that purpose. That the practice should increase in popularity cannot be wondered at, for a sweep of grass land dotted over with Daffodils, Pheasant-eye Narcissus, or other bulbs is infinitely more beautiful than a square, round, or any other shaped bed crammed with bulbs of one particular sort. Planted in the grass, each plant stands clear of its neighbour, or groups with it in a natural manner, whilst planted in a bed all the plants are jammed together, and the form of any individual specimen cannot be seen.

The selection of suitable positions for various sorts of bulbs should be given attention when plantations are being made, for on this the success of the undertaking depends to a great extent. For instance, in places where the grass has to be mown fairly early, those bulbs only should be planted whose foliage dies naturally at an early date, for no leaves should be cut off until they turn yellow; then again notice must be taken of whether the grass forms a thick turf or whether it is somewhat scarce, for in many places such things as Snowdrops and Chionodoxas quickly deteriorate when planted under a thick, dense turf, whilst planted under trees where the grass is fairly thin they increase in vigour.

Then, again, the sizes of the masses must be given consideration, for while in some cases extensive sweeps would be desirable, in others small colonies only would be better fitted. At Kew some very pretty effects are made by planting clumps of Daffodils on the outskirts of Rhododendron bushes, and this is a plan which could be readily adopted by those who have a few bulbs only to plant. In other parts of the gardens at Kew large expanses, an acre or more in extent, are planted, and these in their position make a fine display, but are by no means more beautiful than the small colonies among the Rhododendrons.

The planting of the bulbs should also be carefully managed, for nothing looks worse than quantities of bulbs planted in grass in a formal manner. Straight lines and circles should be avoided, an irregular outline being aimed at. Then when planting a large mass, the bulbs should not all be used in the mass, a number being left to scatter about the outskirts either singly or in small clusters. In the mass itself it might also be found desirable to leave a patch here and there without bulbs, so that when in flower a large group may be relieved here and there with patches of green. Of all exotic bulbs, possibly Daffodils are the best for naturalisation, as they will thrive under very adverse conditions, and are suitable for a great number of positions.

In addition to the common Daffodil, however, there are a number of species of Narcissus and a great many varieties which are first rate subjects for the purpose, whilst spring and autumn Crocuses are extremely useful, especially in places where the grass has to be mown early. Snowdrops and Chionodoxas are better fitted for planting under trees where the grass is thin than for planting in thick grass, though for two years, especially if the ground is good, they may be depended on to flower well even in thick grass.

In some cases Tulips and Hyacinths have been planted in grass and make nice patches of colour for a few years. A few species of Tulip naturalise, and these might be more often used than at present. The practice of saving all bulbs which have not been subjected to very severe forcing, is carried out in many places, and all these are planted out either separately or as a mixture. The majority of these flower the following year, and the greater portion improve in condition, especially if the ground is good.

The planting of bulbs in grass is a rather tedious operation,

especially where large quantities are dealt with. Numerous ways of planting may be adopted, any of which are satisfactory. Two methods which are practised at Kew with success are, firstly, the making of holes 3in or 4in deep with a crowbar, and secondly, removing patches of turf, digging up the ground, placing in the bulbs and covering them over with the turf. For the commoner kinds of bulbs the former method answers well, but for the rarer kinds it is advisable to adopt the latter plan. When planting under the first-mentioned manner it is a good plan to drop a little fine soil into the holes before the bulbs, afterwards filling the holes up with good soil.

For making new plantations, no time is better than the present, as the bulbs will begin to root at once, and they may be looked for to make a good display next spring. Until choice, expensive bulbs have been well tested in cultivated ground, it is not advisable to plant them in grass, for if they should not come up to expectations the planter would probably be discouraged from trying other things.

Almost all the old, well tried varieties of Narcissus are suitable things, whilst others previously mentioned are also suitable. The large flowered Bluebell, *Scilla hispanica*, is worth introducing into the woodland, either used alone or mixed with the common one. On the outskirts of woods *Lilium Martagon* is worthy a trial; in places where the ground is not very hard the Winter Aeonite is a useful subject, the hardy *Ornithogalums* and several *Alliums* may be used by those who like variety, and numbers of other things of which large quantities are obtainable.

—W. DALLIMORE.

## "A GOOD SAMPLE."

The title above applies to the exhibit of a handsome potful of Hyacinths which, through Messrs. Webb and Sons' (Stourbridge) goodness, we are able to present on this page. The variety is Webb's Golden Perfection, and there can be no better proof of the high quality of the bulbs and the attention of the cultivator than that photograph. The fragrance of springtime, and a vision of bright colours in greenhouse and hall, is borne to us in viewing it. Good yellow Hyacinths are not at all common, and this variety is a beautiful bright yellow.

## MUSCARI CONICUM var. HEAVENLY BLUE.

We desire to bring to the notice of any who may not have a stock of it, a plant of such merit that it has only to be seen to be duly appreciated. Messrs. Barr and Sons, of King Street, Covent Garden, London, have a hedge-bank at their Long Ditton nurseries covered with it, and when the flowers are at their best, and they persist a long while too, the display made is specially remembered by all who have seen it. For the small illustration of this subject we are indebted to the Messrs. Barr. Heavenly Blue was sent to them some years ago from Trebizond; the colour is of the brightest and richest shade of gentian-blue imaginable, and large masses produce a wonderful effect in the garden from the end of March to May; the flowers have a delightful fragrance, and are very valuable for cutting, having long stalks, and remaining fresh in water a long time. It was awarded a Certificate of Merit by the Royal Botanic Society.

"A Good Sample."

# NOTES & NOTICES

**Mr. G. Fulford.**

This able gardener, who has been for five years at Presdales, Ware, Herts, relinquishes his situation there on the 27th inst. Mr. Fulford has many prizes from horticultural exhibitions as a testimony to his skill. In an August number we figured the Rose garden at Presdales.

## To Readers and Correspondents.

A number of letters for the Readers' Views page have, of necessity to be held over for a week, and the same remark applies to Correspondents' queries. Our fuller report of the Edinburgh show, of which we had a very short telegraphic report last week, came to us on Wednesday, our printing morning, but our special number this week went some hours earlier to press, and a racy and interesting report is thus held for one week longer. It will appear in our next.

## Weather at Hamilton, N.B.

This morning the thermometer registered 5deg of frost. It was not unexpected, for the last few days were abnormally cold for the month, a north and east wind blowing intermittently. The effects of the frost are already showing themselves, Dahlias, Perillas, Dwarf Beans, and many other things are hanging black in the comparatively hot sunshine which supervened. I have not yet been able to discover what damage, if any, the frost has done to the half ripened cereals in the district.—D. C., Hamilton, September 13.

## A Remarkable Harvest Feat.

Stradbroke, in Suffolk, has been the scene of a remarkable harvest feat. A local farmer the other day carted a field of Wheat during the morning, threshed it in the afternoon, sold and delivered it to a local miller early in the evening. The miller ran some through his mill, and within four-and-twenty hours of the Wheat being taken from the field in which it had grown he had sold flour that had been manufactured from it. This is probably a record in such an unfavourable harvest season as at present.

## Proposed Vegetable Exhibition.

The Council of the Royal Horticultural Society have consented to set apart one of their fortnightly meetings at the James Street Drill Hall, Westminster, next autumn, for an exhibition of high-class vegetables. The Council will not offer prizes; hence the promoters are compelled to invite the kind co-operation of the seed trade. There will be ample space in the present Drill Hall, not only for such classes as are intended, but also round the sides for collections of choice vegetables, within rigidly prescribed limits, exhibited by firms contributing prizes. Such collections should greatly help to create a remarkably representative display of vegetables. As the Council's arrangements for the ensuing year are now in course of preparation, and in which publication all vegetable prizes and classes will be inserted, the promoters, Edwin Beckett, Aldenham House Gardens, Elstree, and Alexander Dean, Hon. Sec., 62, Richmond Road, Kingston-on-Thames, ask to be acquainted of donations or prizes by intending contributors, so soon as possible.

## A Collection of Wild Flowers.

In its report of the recent flower show at Reading, the "Berkshire Chronicle" said: "A word of special praise is due to Mr. George Stanton, the talented gardener at Park Place, Henley, for his group of wild flowers of Berkshire, with their botanical names and their common designations attached. There were some 200 species, all more or less excellent in bloom, which enabled them to be seen to advantage. It may be easily imagined that it took Mr. Stanton no little time and trouble to collect the flowers and name them, and spoke well for his botanical knowledge, and also for the variety and profuseness of wild flowers in the county. Such an exhibit of this character has not been made for twenty years, when Mr. Stanton did the same thing. This is to be regretted, as the exhibit has a good educational value." Similar exhibits, representing the commoner flowers of other counties, might well form an educational feature at shows in different parts of the kingdom.

## Appointments.

Mr. Herbert Hall, for the past five years head gardener at Queenwood, Chertsey, as head gardener to W. H. Herbert, Esq., Newnham House, Wallingford. \* \* Mr. J. Marwood, as head gardener to P. N. Graham, Esq., Northanger, Godalming, Surrey, in succession to Mr. Thos. Glassey.

## Chrysanthemums.

The plants in pots need now considerable attention in watering and feeding. When the pots are fairly full of roots and the soil begins to dry give a copious watering. Liquid manure may be given to those plants which have set their buds. It will suit the plants best if various solutions are given at alternate times so as not to surfeit them with one thing. Liquid made from cow, sheep, or horse droppings at the rate of a peck of manure to 30gals of water is a safe solution. Vary with soot water, and slight top-dressings of artificial manure. Give stimulants only when the soil is moist, not when dust dry.

## An Habitually Fasciated Lily.

The remarkably prolific specimen of *Lilium auratum* which for some years now, has attracted florists and photographers from all parts to view it, has once more burst into bloom in Levensgrove Park, Dumbarton. Last year the blooms upon it numbered 270, but this year that number has been exceeded, and the blooms total over 300. It is now seven years since the bulb was planted. From the first it showed such a wonderful vitality and display of flower as to attract the public attention. The curator of Levensgrove Park has taken the precaution to erect a canvas shelter over the specimen to protect it from the stormy weather now prevalent. For the next ten days or so it is anticipated that hundreds of visitors, from far and near, will visit the park in order to view this magnificent specimen of the Lily tribe.

## August Weather at Belvoir Castle.

The prevailing direction of the wind was W.—total, eight days. The total rainfall was 5.00in; this fell on twenty-one days, and is 2.34in above the average for the month; the greatest daily fall was 1.44in on the 6th. Barometer (corrected and reduced: highest reading 30.208in on the 1st at 9 a.m.; lowest reading 29.597in on the 18th at 9 p.m. Thermometers: Highest in the shade 72deg on the 16th; lowest 38deg on the 26th; mean of daily maxima, 63.93deg; mean of daily minima, 49.03deg; mean temperature of the month, 56.48deg; lowest on the grass, 35deg on the 26th; highest in the sun, 125deg on the 4th, 13th, and 24th; mean temperature of the earth at 3ft, 56.87deg. Total sunshine, 101 hours 20 minutes, which is 64 hours 22 minutes below the average for the month. There were six sunless days. In the three days, August 5, 6, and 7, we had a total of 3in of rain. Such a heavy fall has not been recorded here in August since 1876. Previous to that the records are imperfect. The temperature has been exceedingly low for August, with a great deficiency of sunshine.—W. H. DIVERS, Belvoir Castle Gardens, Grantham.

## The Favourite Carnations.

An English writer in an American contemporary names some of the prize-winning varieties of Carnations as noted in the past summer at English shows. He continues: "The classes for the best blooms in certain stated tints of colour served to show the flowers most prized in this country. Much the Miller and Mrs. Eric Hambro', both white, took the first and second positions in the class for blush or white selfs. In that for rose or pink, a charming new variety named Mrs. G. Sebright, soft pink, was first, and Bomba, rosy pink, was second. Scarlet, red or crimson flowers had as their leaders H. J. Cutbush, a brilliant scarlet; The Sirdar, rich crimson, was second. Sir Bevy was the best maroon; purple selfs were included, but those which are really good are very scarce. It was curious to note that though several new yellow selfs have been introduced since Benary, of Erfurt, sent out his Germania, now some years ago, it was the only yellow self which won a prize in this class. In the class for a buff self, Mr. M. R. Smith's delicate salmon buff-like Germania took all the prizes. The best self flower picked from the whole show was Mrs. G. Sebright: its tint of soft pink is delightful, and its shape very good. We also have the Carnation presented to us in various ways for table decoration, but the blooms employed need to be carefully selected and not be generally too large. Still, the Mahanison type can be employed with admirable effect when properly manipulated."

Trumpet Daffodil, Peter Barr

## Crocuses for Spring Time.

And at their feet the Crocus brake like fire.—Tenny on.

NONE of us who love our flowers can think of the Crocus or hear the sound of its name without a sense of exhilaration. Especially is this so at a season when we are feeling the coming of winter and are thinking of its long and almost flowerless days in the garden. It only needs the mention of the name to transport us, in thought at least, to the spring days when the Crocus opens to the sun and glows with that brilliancy no other flower can give so freely. And now when we are committing to the soil these little fleshy corms which enshrine the life of the flower we feel a double share of this spirit of joy; for are we not sowing in hope to reap in joy the reward of our forethought? We think almost exultingly of the spirelets of colour which shall by-and-by appear through the grass on the dark earth, and which, at the magic call of sunshine, shall open into a brilliant display, whether in disorderly array, in formal lines or beds, or simply in clumps in the border's space. In "cohorts of purple and gold," in masses of almost purest white, in sheets of more ornate striped flowers, the Crocus comes as a welcome sight to all whenever it blooms.

Though not invariably a flower of spring—for we have the Crocus with us as a rule from September's beginning—it is yet indissolubly associated in our minds with that glad season, when we feel the truth of Lord Lytton's words:—

And the Crocus upturned its flame, and burned  
Here and there.  
"The summer," she said, "cometh blithe and bold,  
And the Crocus is fit for her welcoming."

It is then that we enjoy it the most, for it is then that we have the greatest variety of its kind, and it is in the glad spring time that we have it in its most gorgeous forms as seen in the Golden Yellow Crocus and the many lovely garden varieties of *C. vernus*. These are the most gorgeous of the race, and they generally possess, besides the signs of art and choice of the florist in the development and form of the flowers and in their varied colours and markings. Thus, although not the earliest in time of blooming, we may take these first in order.

The most welcome of all the Crocuses of the spring is the Golden Yellow, apparently derived from *Crocus aureus*, but of unknown origin, and easily distinguished from all other known varieties of *C. aureus* by the grey lines on the exterior of the petals. How many generations of gardeners in other countries

it has delighted we know not, but Gerard speaks of it as having "floures of a most perfect shining yellow colour, seeming afar off to be a hot glowing coal of fire," and as having been sent to him by "Robinus, of Paris, that painful and most curious searcher of simples." Since Gerard's day this Yellow Crocus has been a prized flower wherever spring flowers are grown. The earliest of the Crocuses generally grown, it is also an indispensable one, though often past its best before the purple and other coloured varieties we desire to associate with it are in full bloom.

Next to it come the varieties of *Crocus vernus*, and these it is almost impossible, and absolutely needless, to detail. Whether we take the purple, the white, or the parti-coloured varieties we can hardly go wrong among them, and the connoisseur will desire to possess them all. Some of the whites are not so pure as one would like, and hardly any are free from at least faint lines of colour in the interior of the flower, but all are lovely. Of the whites I prefer Mont Blanc, Snow Queen, and one of the newest named Honorine Joubert—a decided acquisition to this class. Of purples, perhaps the deepest coloured is Queen of Purples, but David Rizzio and King of the Blues are also good varieties, while the nearest to an azure blue is given by Bleu Celeste. L'Unique has small purple flowers. It is not so easy to choose among the striped flowers, but Sir Walter Scott, Madame Mina, Pride of Albion, and the new Harlequin, which, however, is variable, are all worth growing. Ne Plus Ultra, which has purple blossoms tipped with white, is indispensable, and Margot is a lovely flower with the inside of the segments coloured a soft lavender, and the outer petals shaded with white.

All of these should be planted in generous masses, and are lovely when seen in irregular masses in the grass. A wealthy man who would plant some millions on a sunny hillside would deserve well of all flower lovers if the place could be seen by all passers. Such a sight would be worth going many miles to see.

But these Dutch varieties of *C. vernus* do not nearly exhaust the Crocuses of spring time, and there are too many other species and their varieties for me to detail in the space the editor has placed at my command. An arbitrary division places among the winter bloomers some which may well be permitted a place among our flowers of the winsome season. There is the lovely *C. Imperati*, one of the earliest and most charming with its violet-purple flowers, fawn coloured outside, and generally feathered with black on this ground. There are many varieties of *C. biflorus*, which, with its best-known forms, *argenteus*, *pusillus*, *estriatus*, and *Weldenii*, ought to be in every garden for the sake of their charming odorous flowers.

Then there is the quaint old Susianus, the Cloth of Gold Crocus, striped brown outside and opening out starlike to show its golden internal colouring. The delightful early Sieberi gives betimes its bright purple flowers, and the typical aureus with its rather numerous varieties is beautiful early in spring as well. With it may be grown *C. stellaris*, as starry as Susianus, and orange with purple-brown featherings; while in the charming little *C. Tommassinianus* we have a free-flowering and hardy little Crocus, pale lavender in type, but variable in its varieties. Then the prolific *C. vernus* has given us such flowers for the elect Crocus lover as George Maw, Leedsii, Ira Aldridge, the pretty *leucorhynchus*—the Pheasant's Feather—and several more. Space fails to tell of the lovely *candidus*, *reticulatus*, *versicolor*, *gargaricus*, *Banaticus*, *Malyi*, and a number more which are welcomed annually with delight when they in the garden do appear.

As for their culture it is of the easiest. Some recommend just covering with soil, but I prefer to plant about 2in deep. Whenever grown, plant them closely together if immediate effect is desired, and with liberal numbers there will, in their season, be full enjoyment of the "Crocuses of the spring time."—S. ARNOTT.

## TRUMPET DAFFODIL, PETER BARR.

Undoubtedly this is the finest white Daffodil or Narcissus at present in commerce, having a pale, sulphury trumpet and ivory-white perianth. It is longer in the crown than Madame de Graaff, and rather less revolute at the brim. It is large and bold in appearance. When exhibited at the Royal Horticultural Society's meeting on the 8th of April last, by Messrs. Barr and Sons, it received a First Class Certificate.

## Bulbs and Their Insect Enemies.

One of our great naturalists remarks that the chief objects in life amongst the insects are to eat as much as they can, and to avoid being eaten. Really, though, this fact is quite observable by any gardener who notices what is going on around him. The perils of insect life are enormous, only their prolific propagation saves many species from extinction. Insects furnish the chief food to many creatures; they are in danger from each other, and from men. About some insects it might be said, indeed, that if they eat a good deal, they are a long while over it, the larval life sometimes lasting many months or even years. Amongst the objects that are specially attractive to insects, from their being often soft and succulent, are bulbs, corms, and tubers. They are specially attacked by some species, but various root-feeders work upwards towards the crowns of plants. Within a bulb, insects find safe lodgment and plenty of food; the smaller foes may prove to be the worse, since their presence is often unobserved till too late.

We naturally, therefore, refer first to those tiny enemies of bulbs belonging to the mite tribe. 'Tis an old joke to say that they are mighty in doing damage to bulbs and other cultivated plants, though so diminutive. Their strength arises from their numbers, and their insidious habits; indeed, the gardeners of the old school seem to have had no idea of the mischief that was chargeable to them. More than one species may resort to bulbs, but *Rhizoglyphus echinopus* is pre-eminently the bulb mite, and a good deal about it was published in this Journal of 1887 and 1888.

[For particulars regarding this pest, we refer the reader to Mr. Abbey's article on another page of this issue.—ED.]

Of larger size, though apt to be overlooked from their artfulness, are those relatives of spiders and mites called the snake millipedes or Juli. One of the largest has the popular name of "Maggie Manyfeet;" but they cannot show a thousand, scarcely above sixty or seventy. These insects are general feeders upon decaying or living animal or vegetable substances, having an evil repute amongst horticulturists; still, the Juli have had their advocates, who assert they do more good than harm, but the case is strong against them. One of the commonest is *J. pulchellus*; though bearing this complimentary name, a gardener cannot like it, since it is very persistent in attacking plants, especially young ones. Its beauty, however, consists in a double row of crimson spots, best seen by magnifier. This insect has been taken seriously damaging specimens of *Eucharis*, and it is often found infesting both roots and bulbs of various species of the Lily tribe. Occasionally it damages young Pansies and Violas. Some Juli feed upon our root crops in fields; it is difficult to extirpate these insects, owing to their habits.

To the centipedes, closely allied to the millipedes, and often mistaken for them, though not so well equipped with legs, we are indebted, since they are notable insect-killers, and we may spare their lives when we can. Mostly, they are owners of mandibles, from which a poison is emitted into the bite they inflict, but they are harmless to human beings in our country. At certain seasons the centipedes are luminous, and leave a shining track upon the ground when crawling after dusk. No doubt they destroy many foes of bulbs, or of the crowns and roots of plants. I am not sure that they have been reported as damagers of bulbs, but the tiny insects called the *Collembola*, so common about frames and hotbeds, probably browse upon their surfaces at times. They are frequently numerous on tubers and succulent roots. Possibly some gardeners style them lice, and one group, the springtails, have a curious jumping apparatus; the crawling species are generally white and shining grubs or larvæ of beetles that live under the earth, sometimes come near its surface and feast upon a succulent bulb. That of the wingless black weevil (*Otiorhynchus sulcatus*), an insect which infests vinerias and Peach houses, often troublesome at roots of Vines and Strawberries; it feeds from September to the spring, a plump, legless, slightly hairy grub. Severe cold has little effect upon these insects. The mature beetles hide during the day, coming out at eventide in May to attack buds and young twigs. Two allied species of this genus, *O. picipes* and *tenebrioides*, pursue a similar course of life, and visit bulbs as well as roots; while larvæ, the first of these is a notable foe of the Raspberry.

Another beetle, strong and wiry, so well-named the wireworm in its larval state, also called the skipjack when winged, will wire into a juicy bulb if it has the chance. When bulbs are planted out upon lawns, they are occasionally visited by the cockchafer grub.

The irrepressible earwig, in its nocturnal wanderings, may arrive amongst bulbs of autumn growth, and enter any opening it may discover in a bulb, possibly make one if the bulb happens to be soft. Some folks doubt whether the common and larger earwig travels through the air; individuals apparently sometimes enter houses by the upper windows. Certainly, the lesser earwig, *Lebia minor*, likes to fly, and parties may be noticed on summer evenings taking excursions from one hotbed to another. We often see them amongst rows of bulbs, but they are not of great importance as enemies. To add one more, the cockroach, or *Blatta* of kitchens and cellars, makes occasional inroads upon plants in gardens and greenhouses; bulbs are attractive to it, and it frequently escapes observation owing to its habit of concealing itself during the daylight.—ENTOMOLOGIST.

[Should any reader have experienced loss from the attacks of other insects, and know of good preventive measures practised against them or any of the foregoing, they might be referred to.]

Grandeur a Merveille. (Referred to on page 272.)

## The English Tulip.

I willingly accede to the editor's request that I should write an article about this most unjustly neglected flower for this present Bulb Number, although I fear that few will read it with more than a languid and perfunctory interest. It is strange that this should be so, for there is no florists' flower more beautiful in form and colouring, and certainly none more refined and interesting in its markings. Its culture is easy, the standard varieties are readily and cheaply procured, and the National Tulip Society holds Northern and Southern shows where all who know more about the flower are received with open arms. There are, however, signs that the worst days for the English Tulip are over—may the signs grow speedily stronger, and strengthen into certainty!

The English Tulip must not be confounded with the Dutch Early, the so-called Darwin Tulips, or what the Dutch growers call Show Tulips or Old Dutch Amateur Tulips. I noticed the other day in a Dutch catalogue a statement that a "number of Old Dutch Amateur Tulips are often included in collections of English Tulips." This statement is scarcely correct, as we English growers only include one Dutch variety, *Comte de Vergennes*, and we only esteem it as a fourth rate flower. The English Tulip is certainly derived from the Old Dutch Amateur Tulip, but while the Dutchmen have done nothing to improve the flower for the last hundred years, raisers in this country have been working hard all the time, and have changed the degenerated, impure, dull coloured, confused old flower into the shapely, pure, brilliant blooms that may be seen at any show of the Tulip Society. I am expressing myself now as a florist or Tulip amateur only, and do not wish anything I write to be construed as a condemnation of the Dutch varieties as ordinary decorative flowers for the general garden, which would be most unjust and undeserved.

It is quite beyond the scope of an article of this kind to go deeply into the matter of culture, especially as I have pretty well exhausted myself in a series of articles written for the *Journal* some years ago. A few cultural notes are all that I can attempt. To begin with, the bulbs should be planted in November, 4in deep and 6in apart, in a bed about 4ft wide, and situate in an airy place, but sheltered from rough winds. The tallest growing kinds should be planted in the middle, and the dwarf ones on the edges of the bed, which should be well drained if situated in a wet or low-lying position. The best soil is the

top spit of a fat loamy pasture stacked for a year, and then roughly cut down, but any good garden soil that has been manured and grown a crop of Celery, Potatoes, &c., the year before will do very well. Fresh stable manure should not be used, as the bulbs do not like it; in fact, they often refuse to face it at all, and the plants die down without blooming.

After planting, the bulbs need no attention until the end of March, when, if the best results are desired, the bed should be covered by glass garden lights about 4ft 6in long by 3ft wide, raised on a temporary framework about 4ft from the ground. After the lights are on, the plants should be watered as often as needed, but care should be taken not to wet the foliage at all, and of course, watering must only be carried out on mild evenings.

Towards the middle of May, or whenever the plants begin to bloom, the surface of the covering lights should be shaded from the direct sunlight, which spoils the beauty of many varieties by causing the colours to flush or run. As the petals fall the shading and lights may be removed and the plants allowed to ripen off. By the end of June, or a little later, the bulbs should be lifted, dried in a cool airy place, cleaned and stored away for planting again in November.

Grown in this way, and in suitable soil, there will be no need to get fresh bulbs again; the same bulbs will serve indefinitely, and if the offsets are saved as they ought to be, and grown on in a separate bed, the collection will rapidly increase in numbers. Offsets should be grown much in the same way as the flowering bulbs. It is, however, better to plant them a month earlier, and no protection at all is needed for them.

It is advisable to change the soil of the Tulip bed every second year, but if this cannot be done a copious addition of decayed vegetable matter before replanting will, in most cases, be quite as effective. A simple plan is to sow the bed immediately after taking up the bulbs, thickly with mustard, and to dig it in about 6in deep, just as it begins to flower. This is rather rough on the mustard, but as the succulent stalks and leaves quickly decay they make an admirable vegetable manure at little expense; rotten garden weeds would do just as well, but if these are used the seeds begin to germinate and become a nuisance.

### Classification.

Tulips are divided into three classes, named *Roses*, *Byblœmens*, and *Bizarres*. The *Roses* have white grounds coloured with some shade of red, which is the more esteemed as it approaches to scarlet. The *Byblœmens* have white grounds

A Field of Keizerskroon at Rush. (See reference on page 261.)

coloured with some shade of purple, which is best liked approaching in colour to blue or black; and the Bizarres are yellow ground flowers, coloured with some shade of scarlet, brown or black. The combinations most esteemed are scarlet on gold ground; black on gold ground; and black on clear lemon ground.

Each of these three classes is subdivided into three sub-classes called breeders, feathered flowers, and flamed flowers. The breeders are the seedling form of the Tulip; they are self colours of some shade of pink, rose, or scarlet in the Roses; purple, lilac, or lavender, in the Byblœmens; and scarlet, orange, or brown in the Bizarres.

Many of the breeders are very beautiful flowers, and are deservedly grown for themselves alone; but their chief interest lies in a most remarkable capacity they possess for what is technically called "breaking," or changing from a self colour, into beautiful variegations. These changes take two principal forms known as feathered, and flamed.

A feathered flower has the petals delicately edged with colour, and a flamed flower has, in addition to the feather on the edge of the petal, a beam of colour up the centre with graceful and distinct branchings, uniting the beam to the feathering. It is in the beauty and perfection of these markings, combined with good shape and perfect purity of base, and filaments, that the merits of a good Tulip lie; but the full understanding of these matters cannot be got by reading about them, and is only attained by study of the flowers and intercourse with growers of experience.

Many excellent breeders never break well, that is, they do not change into either of the two desired forms. Others break into good feathered flowers, but are of no value when flamed. Others are only good when flamed, while a few are excellent in all three states. Breeders of all varieties often break badly, that is, in a nondescript fashion, and should be discarded, as it is but rarely the produce of a bad break ever blooms well, consequently good breaks and the offsets from them are known as good "strains."

It follows from this, that the name alone of a variety is no indication of its value as a show flower, and care should always be taken to obtain bulbs from growers who know the points of the flower as understood in this country.

And now, having given some idea of this beautiful and fascinating flower, let me assure any lover of flowers that he or she would be immensely delighted with a bed of well-grown English Tulips, for there is no sight more gorgeous and glorious in the mass, as there is no flower more dainty or refined when examined minutely. The planting season is rapidly approaching, and as a guide to anyone wishful to start growing, I append a list of the best varieties in commerce.

**ROSE BREEDERS:** Mrs. Barlow, Miss Burdett Coutts, Rose Hill, Annie McGregor, Mabel, Lady Grosvenor.

**BYBLÆMEN BREEDERS:** Talisman, Adonis, Glory of Stakehill, Elizabeth Pegg, Beauty of Litchurch.

**BIZARRE BREEDERS:** Sir Joseph Paxton, Dr. Hardy, Goldfinder, Alfred Lloyd, Sulphur, William Lee.

**ROSES, FEATHERED:** Modesty, Heroine, Mrs. Collier, Comte de Vergennes, Industry, Mrs. Atkin.

**BYBLÆMENS, FEATHERED:** Bessie, Elizabeth Pegg, Adonis, Universe, Stockport, W. Parkinson, Guido.

**BIZARRES, FEATHERED:** Sir Joseph Paxton, Masterpiece, Lord Stanley, William Annibal, Garibaldi, William Wilson, Lord F. Cavendish.

**ROSES, FLAMED:** Annie McGregor, Mabel, Mdme. St. Arnaud, Triomphe Royale, Aglaia.

**BYBLÆMENS, FLAMED:** Talisman, Adonis, Duchess of Sutherland, Queen of the May, Chancellor.

Double Tulip Murillo. (See page 273.)

**BIZARRES, FLAMED:** Sir Joseph Paxton, Dr. Hardy, Samuel Barlow, Lord Stanley, Prince of Wales.—J. W. BENTLEY, Hon. Sec., Royal National Tulip Society.

## Potting Bulbs.

During this month a number of bulbs ought to be potted for winter flowering; indeed, to have a portion in bloom at Christmas it is necessary to pot at once. The bulbs, which should be dealt with at once are Roman and Italian Hyacinths, Roman Narcissus and Paper White Polyantha Narcissus, also Duc Van Thol Tulips. These can readily be had in bloom at Christmas by potting them during this month. There is a large demand for these bulbs, hence it is desirable to obtain the supply early.

In potting Roman Hyacinths, Italian Hyacinths, and Narcissi, four or five bulbs will be required for a 5 or 6 in pot. See that the pots are clean and drained with a few potsherds at the bottom, covering with a little rough material. Mix up a compost with loam, leaf soil, and sand. Half fill the pots with soil, and then place in the bulbs closely together. Cover with soil, just leaving the tips level with the surface. Water the pots with a rosed watering can, and allow them to drain for a day.

After this stand the pots in a shady position under a wall, and cover with ashes a few inches above the surface. They may remain until top growth commences and has pushed an inch or more. The Narcissi will have made top growth and filled the pots with roots in less than a month, while the Hyacinths take longer and can generally remain six weeks. The object of covering the pots with fine ashes is to encourage root growth before top growth, and thus ensure the plants doing well, and coming rapidly into bloom.

After they are brought out of ashes inure them gradually to the light, and keep in a cool frame until necessary to encourage the flowering, which may be accelerated by gentle heat, but when the bulbs are started early they can be brought into flower without a temperature higher than the greenhouse. No water is required during the time the pots are plunged, but after they are exposed the soil must be kept uniformly moist. Treat Tulips the same.

Freesias ought to be potted now, and they will bloom in January or February. It is not necessary to pot these bulbs in too large pots. They are small, and a number can be placed in a 5 in pot, giving each an inch space. Place in a cool frame, and do not plunge the pots under ashes.—S.

# HUMBER BRAND Horticultural Specialties

MANUFACTURED BY THE

## HULL CHEMICAL WORKS, LTD.,

G. CARR ROBINSON, F.R.S.E., F.I.C., F.C.S., Managing Director.

### HUMBER BRAND. "BITTER OIL" INSECTICIDE. HUMBER BRAND.

For Destroying Caterpillars of Winter Moth; Apple Blossom Weevil; Woolly Aphis, or American Blight; Red Spider on Gooseberry bushes; Caterpillars on Gooseberry bushes [see *Special Testimonial from Messrs. E. P. DIXON & SONS on this matter*]; for Washing Hop Bines, for preventing and destroying Fly; and as a Wash for Rose Trees, Chrysanthemums, &c.

"BITTER OIL" has been found a most valuable dressing for Fruit and Forest-Tree Nurseries; also for thoroughly cleansing the inside of Vineries, and as a Winter Dressing for Outside Walls on which Fruit Trees are trained.

"BITTER OIL" mixes readily with cold water—rain-water is to be preferred—forming a soft, milky fluid; there is no separation of oily or soapy matter, and the wash so produced will not scald young and tender foliage, or growing shoots.

## "BITTER OIL."

"BITTER OIL" is a certain and rapid exterminator of all Insect Pests at the minimum of cost to the user, and without the least danger to the tenderest of plants, or injury to the most delicate foliage. It is practically inodorous, and does not leave the slightest stain on plants after spraying or dipping in the strongest solution, when the directions for use for different requirements are adhered to. "BITTER OIL" is not only a safe "killer," but the proprietors claim for it the property of rendering (as its title implies) those forms of plant life subject to insect and parasitic pests dressed with this preparation, absolutely intolerable to them, and consequently immured from their ravages.

### TESTIMONIALS selected from many received, and entirely unsolicited:—

From Mr. J. Allsop, Head Gardener to the Right Hon. Lord Hotham, Dalton Holme, Yorks.—"I am pleased to say that I find it most effectual in destroying Aphid, Thrip, Green Fly, &c. It mixes well with water, and is very convenient to use."

From Mr. J. H. Reynolds, Head Gardener to the Right Hon. the Earl of Yarborough, Brocklesby Park, Lincolnshire.—"After giving 'he Bitter Oil' a fair trial I have much pleasure in testifying to its thorough cleansing powers; more especially was this noticeable on a fine lot of wall Plum-trees, which were becoming badly infested with Green-Fly and other troublesome insect pests. After two applications of 'Bitter Oil' the trees and fruit were left in a clean and healthy state, and are now furnishing a most satisfactory crop."

A further letter from Mr. Reynolds reads—"Plums are showing well for fruit, 'Bitter Oil' keeps them beautifully clean, and is so simple to use, I swear by

it for all these sorts of pests, and mean to apply it this time before they get at all bad."

From Messrs. E. P. Dixon & Sons, the Yorkshire Seed Establishment, Hull; and Gardens and Nurseries, Burton Constable, E. Yorks.—"A few days since we sprayed several thousands of young Gooseberry trees [we are authorised to state that some 15,000 bushes were dressed] which were heavily attacked with caterpillars, with the most gratifying results. Myriads of these destructive pests were instantly destroyed, and after the third day not a single one could be found alive, and though the operation was performed under a burning sun, not the least damage was done to either fruit or foliage. We have used 'Bitter Oil' largely the past two years in our Fruit and Plant-Houses and Nurseries, and have found it thoroughly effectual in destroying Scale, Thrip, Red-spider, and Mealy-bug, without the slightest injury to the most tender foliage."

*Well shake the Oil before measuring off quantity required.*

**STRENGTH:** { For Green Fly . . . . . 1 part Bitter Oil to 100 parts water. | For American Blight and Red Spider.. 1 part Bitter Oil to 50 parts water.  
 { For Black Fly and Thrip 1 " " 80 " " | For Scale and Mealy Bug .. .. 1 " " 40 " "

APPLY WITH A FINE SYRINGE OR SPRAYER.

**PRICES:**—Bottles, Half-pints, 1s.; Pints, 2s.; Quarts, 3s. 6d.; Tins, Half-gallons, 6s.; Gallons, 10s.

## Humber Brand. PLANT CLEANSER and INSECTICIDE. Humber Brand.

*This Preparation, used according to printed instructions, will effectively eradicate all Insect Pests to which Plants are liable, and without in any way injuring the foliage, or leaving any unpleasant smell. From the peculiarly cleansing nature of this preparation, Plants—particularly in towns—have their leafage distinctly improved and invigorated by the use of it.*

### Opinion of a PRACTICAL GARDENER on the "HUMBER BRAND" Plant Cleanser.

From Mr. George Pieker, Head Gardener to Francis J. Pease, Esq., J.P., Haslewood, Yorks.—"I duly tested the 'Humber Brand' Plant Cleanser. I have been waiting to see results before I replied respecting Mildew on Rose bushes . . . I mixed 1 to 8 and syringed on to Stove Plants for Mealy Bug, which we are greatly troubled with. Results, instant death to Bug, without the least injury to roots or foliage—all

that Plant Growers can wish for; then I syringed Rose bushes for Mildew, where foliage was covered with the spores . . . waited to see if the spores covered the foliage again, up to the present they are quite free from the pest; also the Stove Plants remain free of the Bug. . . . The death of insects is assured without injury to tender foliage . . . I believe that it [H. B. Plant Cleanser] will do all that any reasonable person may desire."

### Further opinion of a Practical Gardener.

Mr. Pieker writes further—"The safety that it can be applied over tender foliage, and the certain death of all insect pests, places the Humber Brand Insecticide in the front rank of all insect eradicators. It is a capital insecticide for cleansing trees (Fruit trees) of the American Blight [1 to 8 of water] . . . For winter dressing Vines, Peaches, and Fig trees it will be invaluable. I find 1 part of insecticide to 12 parts of water to eradicate Mildew and Green-Fly; 1 part insecticide to 10 parts of water to kill Thrips,

Red Spider, White Fly, &c.; and 1 part insecticide to 8 parts of water will kill Mealy Bug. The foliage should be thoroughly wetted either by dipping or syringing under and over the foliage. The insecticide will take 4 parts more of water when the water is heated to 145deg. Fahrenheit, or even to 180deg., and at this temperature will not hurt leafless trees. If all cultivated Plants and Trees could be syringed over once a fortnight with Humber Brand, they would always be clean and pleasant to look upon."

**PRICES:**—1s. Bottles; Half-gallon Tins, 6s.; Gallon Tins, 10s.

## Border Bulbs: Some Suggestions.

While there are many plants which look more beautiful in grass than in the border, it is not every garden which has suitable places for this, save it may be, to a small extent. Everyone who has a garden may, however, grow bulbs in beds or borders, and may thus add greatly to the beauty of the garden and to their own enjoyment. The border, also, is the better place for some subjects, such as the Gladiolus, the Tulip, the Ixia, the Ixiolirion, and such other bulbs as require to be lifted and stored away, or to have some protection in winter. It may be taken for granted that almost any plant which can be cultivated in grass may, less naturally, perhaps, be grown in borders or beds, and that a considerable number of others may be used to beautify them. Unfortunately, in cultivated ground, where high cultivation and liberal manuring is followed for the sake of other plants, diseases are much more prevalent to injure the beauty or to destroy the bulbs.

We cannot, however, do without bulbous plants in either the mixed borders or where we have separate beds of flowers. The effects which can be and are produced in the spring garden by massed beds of bulbs are known to all, yet they are less beautiful and give less pleasure than do groups of the same flowers in the mixed borders, where they have as a setting the leaves of the plants which are to bloom later, and which tone down, just as does the grass, the brilliant colouring of some of these bulbous flowers. To secure satisfactory results it is necessary that the planter should study so as to have a proper balance between the different parts of the border at the various seasons at which the bulbs will be in bloom. How often we see the Snowdrop or the Crocus carefully planted at the front of the border, the result being that when these and other early spring flowers are in bloom there is brightness in the foreground and nought but dulness behind.

This is easily avoided by planting these early bulbs further back. By the exercise of some forethought it is easy, also, to have these things so placed that a later-blooming plant of another habit will almost or quite hide the withering leaves from view.

In the border, as well as elsewhere, it is bold planting which tells, and one had better plant a dozen bulbs of a kind than one of each of a dozen different species or varieties; that is, unless you have a liking for a collection of plants, rather than for the

Narcissus, Cecil Rhodes.

decorative effect of the border. It is also the place where those who have but little space can make the most of it by a cunning planting of early and late-blooming flowers together. A clump of spring Crocuses, Snowdrops, Scillas, or Muscaris may have below it a few bulbs of Lilies, which will spear up through the early bulbs and make the place bright again without injury to them. Or a mass of Spring Snowflakes may be followed in autumn by a group of any of the Meadow Saffrons or Colchicums.

A pleasing variant upon this, and one, too, which is beautiful in its effect, is that produced by carpeting a bulb with some dwarf, surface-rooting plant, either to flower with, or before or after the bulb. By judicious consideration many fine effects may be produced, either by the use of contrasts or harmonies. A favourite combination has been a bed of *Myosotis*, through which grow white Tulips. White *Arabis* makes a good groundwork for Tulips, and by its use one can either have a harmony in whites or the contrast of scarlet.

One drawback to the employment of permanently planted bulbs in borders is the trouble they cause by being invisible when they are at rest. If not properly labelled with a good, long, metal tally, they ought to have a stout hardwood wooden pin, renewed when necessary, firmly inserted in the ground in the centre of the clump. This will not only frequently save the bulbs from being injured by the spade, but will also be a good indication of where they are to be found if required for lifting. *SOREWAY.*

### NARCISSUS, CECIL RHODES.

This new variety has been fittingly described as "a giant pale-flowered Queen of Spain." What the parentage is we cannot state, but *N. triandrus* and *N. Emperor* have been suggested. Our illustration on this page, from a sketch by Mr. G. Shaylor, furnishes a good likeness of it. Miss Willmott, of Great Warley, had an Award of Merit for the variety when she staged blooms in the Drill Hall, Westminster, on May 6.

Darwin Tulip, Loveliness, rose.

## The Bulb Mite (*Rhizoglyphus echinopus*).

This pest, though commonly regarded as having a particular liking for the bulbs of *Eucharis*, and frequently referred to as the *Eucharis* bulb mite, attacks the roots of a great variety of plants both under glass and outdoors. As occurring on a bulb of

### The Bulb Mite (*Rhizoglyphus echinopus*).

- A, *Eucharis* bulb, natural size, showing mites.  
 B, Mite enlarged fifty diameters. Body colourless or nearly so, legs very pale rose, with two brown spots on the body.  
 C, Hypopial or harder-skinned form, enlarged fifty diameters.  
 D, Suckers from underneath hypopial form, enlarged 150 diameters.

*Eucharis*, it is faithfully represented in the accompanying illustration by Mr. W. G. Smith, with the mite in its two forms—the mite or *Rhizoglyphus*, and the hypopial or *Hypopus*. Into these extremely curious transformations I do not propose to enter, but content myself with the matter most interesting to cultivators.

In the case of bulbs the mite usually lives between the scales, and is protected by the outer or dead ones. The seat of the mite is well shown at A, though the mites are only just or scarcely visible to the unaided eye. The mites abstract the juices of the plant and set up decay, the foliage becoming sickly and the plants very unsatisfactory in all respects, at most continuing a sickly and lingering existence, rendering them worse than worthless. Perhaps the bulbs most liable to attack are *Eucharis* and *Vallota*. When such is the case the best plan is to allow the soil to become rather dry, then turn the plants out of the pots, remove all the soil, all injured roots, and scaly matter from both the base and neck of the bulbs; then wash them thoroughly in a solution made by dissolving 2oz of soft soap in 16oz of soft water by boiling, adding a lump of soda about the size of a nutmeg, and when dissolved remove from the fire and place in a wineglassful of paraffin oil, stirring briskly until amalgamated, then dilute to 1 gallon with boiling soft water. When the solution is cooled so as to bear the hand in it, dip the bulbs in it and rub the solution into every fissure with a soft brush. This treatment will destroy all mites reached, and in the course of a few days the bulbs may be potted in small, clean, well-drained pots of rather sandy turfy loam and peat, embedding them in and surrounding with crushed charcoal, plunging the pots in bottom heat if convenient. If the soil be kept moderately moist, but not wet, fresh roots will, in all probability, soon be emitted, and the plants grow well.

Other insecticides, such as Fir tree oil, may be used for cleansing the bulbs from the mites, cleansing them at once in clear water, preferably at a temperature of 110deg, and when drained dry potting. It is not always, however, convenient or even advisable to dissolve the bulbs, but treat them in the pots. For this purpose Clibran's *Eucharis* mite killer has attained considerable repute, and applied according to the instructions is efficacious. It, however, rather retards the growth of the plants to which it is applied for a time, but this is brief, the plants soon recovering and starting into vigorous growth, hence the insecticide acts both that way and as a fertiliser.

Similar remark applies to Little's soluble phenyle at a strength of one part in 1,000 parts of water, or one fluid ounce to 64gals of water. Soot water also appears, probably from the ammonia it contains, very objectionable to the mites. The soot, fresh, light and dry, should be made into a paste with water before pouring on the body of water, say 30gals to a peck of soot paste, then stir well with a broom and sprinkle on a couple of handfuls of powdered quicklime, and use the broom again. After standing twenty-four hours a scum will form on the surface, and this must be skimmed off. Underneath, with the exception of the sediment at the bottom, the water will be clear and bright, though a light brown colour. This soot water may be used for watering bulbs troubled with a mite as a cure, or as a preventive, diluted with an equal volume of water, and for general watering purposes at a quarter strength.

The bulb mite attacks the roots of many plants. I have found it on the roots of the *Gladioli*, especially the *Bride*, on the roots of *Cucumbers*, especially the root stems associated with such gentry as eelworms and whiteworms, on the corticated roots of *Vines*, and even adventitious roots, and not unfrequently on the knotty roots of stone fruits.

In one garden it has completely annihilated the *Snowdrop*, and in another rendered *Lily of the Valley* very patchy. What is the cause? Candidly I do not know. Where it is it does a lot of harm, and probably the best means of riddance outdoors is to soak the ground thoroughly with lime water made by placing a peck of quicklime, light lumps, in a tub, and pouring on 30gals of water, stirring well and letting stand forty-eight hours or twice as long, then using the clear lime water only. Probably, too, lime water does considerable good by acting on organic matter, at any rate the plants thrive afterwards.—G. ABBEY.

## Hyacinths and Tulips for Exhibition.\*

To obtain first-rate spikes of these showy spring flowers there are several cultural items of importance. In the first place, many think large spikes is a matter of selecting the bulbs. This I have proved is only in a small degree the case; for I would rely more upon good culture after having obtained *medium-sized solid bulbs*. I have found large bulbs have a tendency to throw more than one spike, and this is not at all desirable for exhibition purposes. The compost recommended is loam two parts and one part thoroughly rotted manure. To this is added half a part of road grit or coarse silver sand. The whole is well mixed and got into a state of even moisture—that is, neither wet nor dry—and placed under cover for use. Pots are cleaned and crocked ready, the 5in size being employed, and each has one bulb. The month of October is a good period for potting. If left later the bulbs may suffer. Another object of fairly early potting is to get an ample supply of roots before the tops grow to any extent.

This, to us, is the chief element of success in bulb culture in pots. I have seen *Hyacinths* potted and put into peat straight away, and the owner wondered why the bloom spikes refused to come out of the bulbs. The way to pot bulbs is to fill each pot with earth, press it in fairly firm, then scoop out a hole with the fingers to hold the bulb. Too often the soil is pressed in, then the bulb is pressed down on that. The consequence is the soil immediately under the bulb becomes very hard, and when the roots begin to grow, the bulb is pushed out of its place.

As the bulbs are potted, we stand the pots on a firm bottom of ashes in a cool frame, not that they require protection; as they are covered, but the glass may then be put on if necessary to guard off over-abundant rain. We do not water the earth after potting, but place an inverted flower-pot over each bulb. This protects the growth later. Then we cover the whole with cocoa-fibre or ashes, the former for preference, because ashes—at least fresh ashes—contain sulphur enough to do harm sometimes.

The *Hyacinths* are left in this covering for about three months, then examined. Ample roots will be found, and the tops will have advanced very little. The plants now need light. We shift them from the covering, but for a day or two leave the inverted flower-pots. Then they are removed to shelves near the glass in cool greenhouses to come on gradually. Most *Hyacinths* lose in size by being forced.\* Slow growth in a cool house is the thing to bring the spikes well up from the bulb, and large. Water through the winter months is not often required, but as the spring advances moisture at the roots is needed pretty often.

I would not give anything except clear water until the spikes begin to show colour; then they require something to push them out to their utmost extent. Nitrate of soda is a capital stimu-

\* The Royal Bulb Growing Society of Haarlem offer £24 in prizes for Tulips and *Hyacinths*, to be competed for at a meeting of the Royal Horticultural Society of England in March, 1903. Particulars of this competition may be received from the Secretary, R.H.S., 117, Victoria Street, Westminster, S.W.

lant. Use this at each watering at the rate of 1oz to 2 gallons of water. Hyacinths cannot be successfully flowered the second year; we therefore plant the bulbs in odd places in the garden. Here they produce useful bits of blossom for cutting. The varieties most adapted for exhibition are nearly all single kinds, the doubles not being so large or handsome generally.

Lord Macaulay, Charles Dickens, Fabiola, Gertrude, Moreno, Roi des Belges, Ven Schiller, and Mrs. Beecher Stowe belong to the crimson and rose shades.

In whites, La Grandesse, Mont Blanc, and Madame Van der Hoop are good; and Grandeur à Merveille is an excellent blush white, shown on page 267 from an illustration kindly lent by Messrs. E. P. Dixon and Sons, of Hull.

Czar Peter, Grand Maître, Lord Derby, and King of the Blues are fine in different shades of blue.

In General Havelock we get quite a black shade of colour. Ida is the best yellow; Koh-i-noor, salmon pink, is a semi-double Hyacinth that will be satisfactory for show purposes.

**TULIPS.**—When well grown, the Tulips are among the most showy of spring-flowering bulbs, the colours being so rich and varied. For Tulips we use a compost of sound loam and a fair sprinkling of grit. We do not like manure in the mixture, for anything that tends to draw the leaves spindly is a detriment to good culture. Six-inch pots are employed, and in each we place three bulbs. The former are prepared by being drained with potsherds, and a portion of the rough bits of soil is placed over them. The pot is filled and pressed in fairly firm, then holes are made to take the bulbs. In selecting these for each pot, try to get them as even in size as possible. Then we stand the pots on a bed of ashes in a cool frame, and cover the whole—pots and bulbs—to a depth of 6in with coëa fibre. The Tulips are left to themselves, except in the case of very heavy rains. They then require some protection, as it is not desirable to let the earth get soddened. If potted in October, which is a capital month for the work, by January they should be taken from the covering material. Place the pots in a cool greenhouse, and just keep away frost. In this position the growth is steady and firm. Tulips for exhibition may not be forced. It is only a few of the less fine sorts that are adapted for that mode of culture. Give the plants plenty of room, also abundance of air, that the leaves may grow in a sturdy manner. They will also require from this period plenty of moisture. Once let the roots get dry, the leaves will soon exhibit its effects.

As a stimulant for Tulips, I like manure water from the farmyard, and for a change soot water. This gives a deep green tint to the foliage. Tulips to be finely grown should throw the bloom well up from the bulb, with stiff leathery leaves that do not lop

all ways, and, of course, the blossom must be large. These bulbs will flower fairly well the second year, but not give fine flowers.

I do not grow many varieties, but rather select those which are distinct and possess other qualities.

There is no better white than White Joost van Vondel. This is a sport from Joost van Vondel, rosy crimson. Proserpine is a beautiful flower of a bright rose shade. Keizerskroon is scarlet edged yellow. This is a grand Tulip. Fabiola has blossoms of red and white; Ophir d'Or is the best yellow; Dresart is a dark crimson; Vermilion Brilliant, a dazzling red, is excellent. Van der Neer, purple, is very effective. Duchesse de Parma, orange and crimson, is good. Cottage Maid, white, edged pink, a well-known favourite. The three Pottebakkers, white, yellow, and scarlet, are first-rate, too, for pot culture. The above are single-flowered. These appeal to me, as they do to most people, as being the more handsome of Tulips. Alba Maxima, Imperator rubrum, deep scarlet, and Tournesol, red and yellow, are three of the best doubles.—H. G., Woking.

## DOUBLE TULIP, MURILLO.

This is one of the most pleasing double Tulips extant; indeed, for our own choice, we would probably accord it the first place. El Toreador is very brilliant; Imperator rubrorum is a glowing scarlet; rosea perfecta, and Rose d'Amour, and Salvator Rosa, with the Tournesols and Vuurbaak, are each meritorious and beautiful, but Murillo, of rose colour and flushed with white, ever remains a most charming and lovely flower. It grows 11in high, the stalks being stout, and the flowers very full. They expand widely under the sun's influence, furnishing an exceedingly cheerful reflection, for three weeks or a month, in good weather. It is a midseason bloomer, and to obtain the best effect from it, it is advisable to plant it in masses alone. For our illustration of this variety on page 269, we are indebted to Messrs. W. Clibran and Sons, of Altrincham.

## PARROT TULIPS.

The Parrot or Dragon Tulips bloom at the same time as the Cottage or Darwins, and no doubt receive their popular names from their gaudy and brilliant colours. Their large loose petals are lacinated at the edges, giving the flowers a wonderful character and charm. As an instance of how little known they are by the general public we need only cite a case which occurred with ourselves. Having a large assorted bunch of all kinds of Tulips, we were feign that others might see and admire them, and showing them to some non-gardening friends their astonishment was great at seeing the Parrot varieties, the like, for colour and weird elegance, they declared they had never before seen. The admiring throngs at Kew who gaze at the beds of Parrot Tulips there, would further prove that this flower is appreciated wherever it is grown or seen. The illustration on this page, and that of Darwin Tulip Loveliness, are from Messrs. J. Veitch and Sons, Ltd., Chelsea. To ensure a good display of this kind of Tulip, it is commendable to choose only sheltered beds or borders, and a sandy loam, plant in the bulbs 4in apart. They may also be grown in pots or hanging baskets, in the usual manner. For providing cut flowers, we are great in their praise. There are half a dozen good named varieties, including Large Yellow, Crimson Beauty, Perfecta, and Amiral de Constantinople.

## Gadding and Gathering.

"HERE AWA', THERE AWA'."

In a visit to Long Ditton during the Tulip's flowering season, it was part of my business to make note of some of the varieties, and it is to these that the present notes pertain. Each variety is grown in separate squares or parts of a lengthened bed, more numerous if it is popular, like the Cottage Tulip, Golden Queen, or less so if its merits are not so well known or appreciated. The short selection as under are all Darwin varieties—Tulips with handsome, though not as a rule large, and distinctly beautiful flowers, which are at perfection during the earlier weeks of May. They are confidently recommended to all for bed and border culture, or for planting in grass in the manner recommended by Mr. Dallimore in another page in this present number. As cut flowers they are stately and elegant, and for gentle forcing they are invaluable.

### Tulips at Ditton.

**DARWIN VARIETIES.**—*Antony Roozen*.—Very large and robust, pink edge, with deeper toned centre. Grows 2ft.

*Clara Butt*.—A charming flower, colour rosy-salmon. One of the finest, growing fully 1½ft.

Parrot Tulip, Crimson Beauty.

*Circe*.—One which my notes refer to as mahogany-coloured, with whitish edges to the segments. Others describe it as delicate heliotrope, which is a very different shade, surely; at any rate it is a lovely flower.

*Donders*.—Rich, dark vermilion, with dark violet centre, edged white, and a tall grower, over 2ft.

*Edouard André*.—One of the earliest. Deep rose-purple outside, mauve within, and blush white centre. Well spoken of.

*Fanny*.—A sweet variety, rose-lilac, and blooms with the earliest.

*Fra Angelica*.—Rich dark chestnut-red, segments strong and shine brightly. A fine Tulip.

*Grand Monarque*.—Very handsome, deep, rich purple flower.

*Hecla*.—Crimson, of great depth and richness.

*Loveliness*.—One of those delightful satiny rose-coloured flowers, of great refinement. Beautiful as a cut flower.

*Maiden's Blush*.—Later than many of the other sorts, this is a great favourite with nearly everyone. It is rose-blush, a colour always sweet.

*Peter Barr*. A very dark maroon, the globular flowers having a bluish "bloom" over them.

*Pride of Haarlem*.—Distinctly one of the finest of its class. "A brilliant, deep salmon-rose, shaded scarlet." The flowers are large, on very long stalks.

*Purple Perfection*.—The name is sufficient guide.

*Rev. H. H. D'Ombain*.—A rich crimson vermilion, not to be omitted by any chance.

*Scylla*.—Very lovely, deep rosy-cerise.

*Suzon*.—Rose-salmon, with bright blue centre, exquisite in all particulars.

*Tak Van Poortvliet*.—I find this Tulip has a special cross (X) against it in my note-book, which signifies special merit. The colour is a warm, glowing salmon rose—salmon-crimson, I might almost say.

*The Sultan*.—Well described as the Black Tulip. Contrasts grandly with a light variety. The flowers are strong and held erectly.

*White Queen*.—White, with a tinge of pink.

#### Cottage Tulips.

Under this head are placed these models of all that is loveliest and most admirable in Tulips, including such familiar kinds as Billietiana, Bouton d'Or, elegans, Golden Crown, Vivid, retroflexa, fulgens, and Picotee. They are the Tulips for bedding, and many of them succeed well placed under grass sward. As these seem to be much better known than the Darwins, it may suffice to give a list of those which receive, perhaps, the greater share of notice. This would include:—

|                       |                |
|-----------------------|----------------|
| Acuminata             | Goldflake      |
| Annie                 | Harlequin      |
| Billietiana           | Lac Doree      |
| Bouton d'Or           | Macropila      |
| Bridesmaid            | Maid of Honour |
| Bronze King           | Orange King    |
| Chameleon             | Picotee        |
| Corona lutea          | Retroflexa     |
| Didieri               | Royal White    |
| Didieri alba          | Strangulata    |
| Eastern Queen         | Snowdon        |
| Elegans               | Sweet Nancy    |
| Elegans lutea         | Sylvestris     |
| Empress of China      | The Fawn       |
| Faerie Queen          | The Moor       |
| Flava                 | Vitelina       |
| Fulgens               | Vivid          |
| Gesneriana spathulata | Yellow Crown   |
| Golden Crown          | Yellow Gem     |
| Golden Lion           | Yellow Queen.  |

Descriptions of these will be found in Messrs. Barrs' catalogue, as well as in those of some of our leading bulb merchants. I should, in conclusion, call attention to two newer varieties: Mrs. Moon, a beautiful brilliant yellow, and La Merveille, salmon-rose, suffused with orange-red—both of them good, but especially Mrs. Moon.

#### Tulips in Ireland.

I refer particularly to those from Messrs. Hogg and Robertson, of Rush, Co. Dublin. Mr. Richard Dean has something to say of bulb growing there in his article on page 261, and it will be remembered that a letter of Mr. Burbidge's on "Bulb Culture in Ireland" was printed in the Journal for December 19th, last year. Mr. Burbidge mentioned that at Rush "the wind is terrible at times, as it sweeps across the sandy plateau, either from the north-east, or when the spring gales tear furiously across the little fields or gardens from the sea." By glancing at the field of Keizerskroon Tulips on page 263, kindly lent to illustrate these notes, it will be seen that each little plot is fortified by sloping earth embankments or low mud walls; hedges of the oval-leaved Privet and other hardy shrubs are in places used in addition to, or in combination with, the earth-banks, so as to break or filter the wind. The land that has been under trial at Rush for seven or eight years consists of small irregular plots, and altogether comprises some twenty-one acres. Both Messrs. Hogg and Robertson, Baylor Hartland (of Cork), and Miss Currie (of Lismore) annually exhibit numbers of beautiful displays of Cottage, and Darwin, and species of Tulips in London, comprising such varieties as I have named in the foregoing lists. The Irish flowers seem even to excel in size and brilliance of colouring.—WANDERING WILLIE.

## Societies.

### London Dahlia Union, Sept. 13th, 17th, and 18th.

This three days' show was opened in the Royal Aquarium, Westminster, on Tuesday last. It was a good show. The trade firms were forward strongly, and competition in the open classes, and also those confined to amateurs, was fairly keen. There were seventeen certificates awarded to new seedling varieties, these including thirteen Cactus sorts and four Shows. The general arrangements of the exhibition were managed by Mr. John Green, chairman, and Mr. Richard Dean, the secretary.

#### Show and Fancy Varieties.

OPEN CLASSES.—for twenty-four blooms, distinct, there were six entries, and Mr. J. Walker, Thame, repeated his National success by carrying off the first prize. The stand was undoubtedly a strong one, though some of the flowers appeared a little coarse. The varieties were Muriel Hobbs, Harry Keith, Majestic, Jas. Cocker, Comedian, Mrs. Langtry, Chieftain, Wm. Powell, Florence Tranter, Jas. Hobbs, Mrs. Gladstone, Comte de la Sauv, John Hickling, Daniel Cornish, Mrs. Morgan, Perfection, Diadem, Matt. Campbell, Arthur Ocock, Sidney Humphreys, Maud Fellowes, Nubian, Ethel Brittan, and Victor. Mr. Chas. Turner was second with smaller though more refined flowers; a few of the best were Florence Tranter, Colonist, Merlin, Maud Fellowes, Arthur Rawlings, and Duchess of York. Mr. W. Treseder, Cardiff, was third with a good, clean exhibit, and Messrs. Keynes, Williams and Co., Salisbury were fourth.

In class 2 there were three contestants, and Mrs. M. V. Seale, Vine Nurseries, Sevenoaks, came out first with a very strong stand, the varieties being Perfection, Daniel Cornish, Gracchus, Miss Cannell, Wm. Rawlings, Mrs. Gladstone, Colonist, John Hickling, R. T. Rawlings, Hugh Austin, Florence Tranter, and J. T. West. Mr. J. R. Tranter, Henley-on-Thames, was second with good blooms of Colonist, Mrs. Gladstone, Harry Keith, and Marjorie; while Mr. H. Blundell was third.

#### Amateurs, Open.

The amateurs turned out well in the class for twelve blooms, Show and Fancy varieties, there being no less than nine competitors; Mr. Thos. Hobbs, Downend, near Bristol, being first with a good level exhibit. His varieties were Arthur Ocock, Mrs. Glasscock, Perfection, Eldorado, Emin Pasha, John Walker, George Hobbs, Mrs. Slack, R. T. Rawlings, Willie Garratt, Harrison Weir, and Arthur Rawlings. Mr. T. Anstiss, Brill, Thame, was second, having good flowers of Rev. J. B. M. Camm, Hero, Florence Tranter, and John Walker. Mr. S. Cooper, Chippenham, was a good third, and Mr. H. Blundell, gardener to Mrs. G. St. Pierre Harris, Orpington, fourth.

The class for six blooms brought out no less than ten entries, the general quality, however, was below the mark, Mr. S. Cooper, Chippenham, winning the premier award with a good board; his varieties were R. T. Rawlings, Emin Pasha, Perfection, Mrs. Gladstone, Ethel Brittan, and Mrs. Saunders. Mr. T. Anstiss was second with good typical blooms of Goldsmith, John Walker, and Chieftain. Mr. E. Jeffries made a fair third, and Mr. E. West, junr., Henley-on-Thames, brought up the rear.

#### Cactus Dahlias, Open.

Class 5, for twelve varieties of Cactus, six blooms in each bunch, brought out six competitors, who were all in strong form, and the judging must have given the adjudicators considerable trouble. Messrs. J. Burrell and Co., Howe House Nurseries, Cambridge, proved the victors. Their varieties were Hubert, Mrs. Ed. Mawley, J. W. Wilkinsen, Ella, Vesta, Ianthé, Albion, Pleasance, Lyric, Enchantment, Maurice, and Ida. Mr. Burrell is to be congratulated on the brevity of his names, and it is a pity the other Dahlia raisers do not follow his example, instead of multiplying names. Messrs. J. Stredwick and Son, St. Leonards, were second with beautiful bunches of Comet, Mary Farnsworth, H. J. Jones, Miss F. M. Stredwick, Etna, Vesuvius, and Eva. Mr. Chas. Turner, Slough, was third, having good bunches of Lord Roberts, Vesta, Mrs. H. J. Jones, and Slough Rival; and Mr. S. Mortimer brought up the rear.

Class 6 was for twenty-four varieties of Cactus blooms on boards, distinct. Here there were six entries, and a very strong class they made, too. Mr. W. Treseder scored here with a strong board. The varieties were Mrs. Ed. Mawley, Lucius, Mrs. H. J. Jones, Stella, Artus, Britannia, Wm. Jowett, Mrs. Carter Page, Clara G. Stredwick, Maurice Walsh, Wm. Clark, Vicountess Sherbrooke, Rosine, Genista, Arab, Mrs. J. J. Crowe, Up-to-Date, Lottie Dean, Mrs. Goddard, Vesta, Uncle Tom, Lyric, Ringdove, and J. H. Jackson. Messrs. J. Burrell and Co. were second with a board of very refined flowers, the best being Premier, Mrs. J. J. Crowe, Conrad, Ida, Albion; the best white to date, Mrs. Ed. Mawley, Pleasance, and Anabel. Messrs. Keynes, Williams and Co. were third, and Mrs. M. V. Seale fourth.

In the smaller class for twelve blooms, distinct, there were seven exhibitors. Mr. H. A. Needs, Horsell, Woking, was

deservedly awarded the premier position for an excellent stand; his varieties were Mrs. J. J. Crowe, Mrs. Carter Page, Mrs. Ed. Mawley, Galliard, Uncle Tom, Lord Roberts, Mrs. H. A. Needs, Mrs. H. J. Jones, Miss Winchester, J. W. Wilkinson, Eclipse, and J. Weir Fyfe. Messrs. Keynes, Williams and Co. were second to the amateur; their best varieties were Imperator, Ajax, Mrs. J. J. Crowe, and Princess. Mr. W. Baxter, Woking, was third, and Mrs. M. V. Seale fourth.

#### Amateurs.

In the classes confined to amateurs some excellent flowers were seen. Mr. P. W. Tulloch, of Hove, was a splendid leader for the nine, in bunches of three, having massive and beautiful blooms of Lucifer (well worthy of a certificate), a seedling of his own. Also Florence, P. W. Tulloch, R. Dean, Ajax, Mrs. Carter Page, Goldfinch, and Bessie Mitchell. Second came Mr. H. L. Bronsson, junr., from Sidcup, with well staged and showy blooms of Lord Roberts, Mrs. J. J. Crowe, Galliard, and others. A good stand, but lacking the size of Tulloch's, though more varied. Mr. W. Peters followed third, and staged very poorly.

For the six in bunches of three, winners were Mr. L. McKenna (gardener, Mr. Cretchley), Twyford, first, but who staged badly; second, Mr. Mawley, who has often shown better; third, W. Peters; and fourth, W. C. Pagram, out of seven entries. Mr. H. A. Needs was distinctly the victor for twelve blooms on boards, having a fine set, there being Floradora, Mrs. H. A. Needs (rich ruby crimson), Lottie Dean, Mrs. Mawley, J. F. Hudson, Mrs. C. Page, Lord Roberts, and others. Mr. E. West, junr., of The Laurels, Henley-on-Thames, was second with Rosine, Canary, J. Weir Fife, and J. F. Hudson. Mr. W. Peters and S. Cooper were placed so. For the six ditto, the order ran thus: Messrs. Needs, Mawley, and West, each staging beautiful flowers. Mr. Tulloch led in class 12 for a vase of twelve blooms; Mr. Needs second; and Mr. A. Taylor, East Finchley, third.

#### Cactus Dahlias, Open.

For three vases, each containing nine blooms, a number entered but two exhibitors—Walker and Treseder—were disqualified through not having the stipulated number of flowers. Mrs. M. V. Seale led, Mr. Needs following, and Keynes, Williams and Co. third. For Mr. F. W. Sharp and R. Dean's prizes in class 14, the winners were Messrs. Seale; Keynes, Williams and Co.; and J. Walker, placed so. Mr. S. Mertimer beat Keynes, Williams and Co. for six blooms of one variety on a board, he staging perfect Mrs. Mawley, and they, Clarence Webb. The third award fell to Messrs. Stredwick and Son with H. F. Robertson, a clear yellow. Six competed.

#### Pompons, Open.

For twelve varieties in bunches of ten, the results were: first, Mr. C. Turner with Thalia, Daisy, Montagu Wootton, Elsa, Cyril, Adelaide, Minnie, Bacchus, E. Hopper, Douglas, Jessica, and Nerissa; second, J. Burrell and Co.; third, Mrs. M. V. Seale; and fourth, Mr. J. Walker.

AMATEURS.—Six varieties in bunches of six. Here Mr. W. C. Pagram led off, followed by Mr. S. Cooper, Mr. W. Peters, and Mr. T. W. Playsted.

SINGLE DAHLIAS, OPEN.—For twelve, in bunches of six, Mrs. Seale, with Edie Oblein, Columbine, Trilby, Alice Seale, and Huntsman, was foremost; Messrs. J. Walker and C. Osman coming second and third. Mr. Mawley led for the six varieties, having strong and good blooms, including Naomi Tighe, Polly Eccles, Tommy, Demon, Victoria, and Aurora. They were substantial and refined. Rev. Spencer Pearce, of Woodstock, came second; and third, Mr. C. Osman, of Chertsey.

#### Miscellaneous Exhibits.

Amongst the firms contributing Dahlia collections were the following:—Messrs. Hobbies, Limited, Cannell and Sons, Dobbie and Co., J. T. West, M. V. Seale, Cutbush and Sons, T. S. Ware, Limited, E. F. Such, and J. Walker. Messrs. House and Son contributed hardy flowers, Blackmore and Langdon had tuberous Begonias, and Lawes, of 59, Mark Lane, London, staged samples of their fertilisers.

#### Awards.

Gold medals were awarded to Messrs. H. Cannell and Sons, J. Burrell and Co., and Hobbies, Limited.

Silver-gilt medals to Messrs. Dobbie and Co., J. T. West, I. House and Son, Blackmore and Langdon, M. V. Seale, and Hobbies, Limited (for Roses).

Silver medals to Messrs. J. Walker, W. Cutbush and Son, T. S. Ware, Limited, and E. F. Such.

#### Certificates of Merit.

The following Cactus varieties received Certificates of Merit:

*Eva*, pure white, a beauty, from Stredwick.

*Tesarius*, spoken of as an improvement on Alpha. It is a yellow-ground Cactus Fancy, speckled and striped crimson; good form; from Stredwick.

*H. J. Jones* must not be confused with Mrs. "H. J." It has a clear yellow centre, with rosy pink tips. (Stredwick.)

*Etna*, quite a new colour, a peculiar purplish lilac, not bright. (Stredwick.)

*Relcap*, one of Hobbies' novelties, bright crimson and "spidery."

Bulb Lifting on Bath's Floral Farms. (See page 261.)

*Winsome*, an ivory white of moderate size. (Hobbies, Ltd.)

*Mrs. T. Cherry*. Distinct; it is purplish red, overlaid with salmon. (Keynes, Williams, and Co.)

*Prince of Orange*, from the same source as the foregoing. A grand thing, with golden centre and reddish edge.

*Enchantment*, lilac mauve, with yellowish base.

*Albion*, ivory white. (Burrell and Co.)

*Maixman*, rich purplish crimson, a well-built, bold flower. (Mr. S. Mortimer.)

Messrs. Treseder had *Charm* and *Minnie West*, both of which we could not discover. They had also Show D. *Mrs. W. Treseder*.

The following Show varieties were certificated:

*Gold Mantle*, a beautiful bloom, rich golden, with saffron-gold suffusion. (Keynes, Williams, and Co.)

*Henry Clark*, purplish tipped flutes, creamy in the centre of each. (Keynes, Williams, and Co.)

*A. M. Burnie*, cinnamon-buff, from Mrs. St. Pierre Harris, Orpington.

### Derby Horticultural, Sept. 10th and 11th.

In unsettled weather this show was held on September 10 and 11. Groups of plants made a distinct feature, and there was a good competition. Grapes were finely shown, though they might have been more numerous in some of the classes. Vegetables in all the divisions provided, were excellent, and considering the trying season classes filled well.

Cut flowers were not set up in great numbers, but some fine Dahlias were noted as well as very fair boxes of Roses.

For groups of plants, prizes—six in number—ranging from £20 to £4 were provided. The plants were arranged in a circular tent, as segments of a circle on spaces of 200ft., and made a most effective display. Mr. J. Ward, gardener to J. H. Oakes, Esq., was placed first, his Crotons being examples of the highest culture. Mr. J. Thompson, gardener to G. H. Turner, Esq., proved a worthy second; Mr. J. S. Sharpe was third with a highly finished group, and Mr. Geo. Woodgate, gardener to Sir Oswald Morley, was a creditable fourth. In the cut flower classes for Dahlias, Roses, Marigolds, &c., Messrs. C. Carrington, S. Kerry, and J. Ward were the chief prizewinners. For a bouquet Mr. J. Norman was first, Mr. J. Wood second, and Miss Bayley third. Mr. Norman was again first with a vase of cut flowers, being followed by Mr. J. H. Goodacre, and Mr. H. Bond, gardener to — Malin, Esq.

There were only three entries in the class for a decorative dessert table. Here Mr. Goodacre's fine fruit easily carried him to the front. The arrangement of flowers on this table was also well carried out; the material used consisting chiefly of Montbretias and Francoas. Good Madresfield Court and Muscat Grapes, Clapp's Favourite Pears, Victoria Nectarines, Brown Turkey Figs, finely coloured Bellegarde Peaches and Washington Apples and well grown Melons were some of the dishes shown. Mr. J. Read was second, Mr. Ward third. For three bunches of Grapes, any white variety, Mr. Goodacre won with large bunches of Muscat of Alexandria; followed by Mr. H. D. Smith and Mr. S. Barker, gardener to the Duchess of Newcastle. The last-named was placed first in the class provided for three bunches of either Madresfield Court, Black Hamburgh, or Muscat Hamburgh, showing highly finished Madresfields. Mr. Goodacre second with the same variety, and Mr. Evans third with small berried but well coloured Black Hamburgh.

Mr. Goodacre came to the front again in the class for any other variety of black Grapes, showing huge bunches of Barbarossa, Mr. Dawson following with really fine Gros Colman, and Mr. Smith, who had good clusters of Alicante. Mr. Ward was first for a Melon, and Mr. Goodacre occupied the premier position for both Peaches and Nectarines.

There was a meritorious display of Apples here, Mr. Goodacre was placed first for six dishes of splendidly coloured examples of Gascoigne's Seedling, Faise d'Hoffinger, Lady Sudeley, Ribston Pippin, Washington, and Mother. Mr. G. Woodgate second, and Mr. H. D. Smith third. Mr. Goodacre was also first for a dish of dessert Pears, showing a good dish of Marguerite de Marillat.

Vegetables were well shown. For the three prizes offered for a collection by Messrs. Sutton and Son, Mr. J. Hudson was first, having fine Celery in his stand. Mr. Thos. Smith was second, and Mr. J. Read third. Messrs. Webb and Sons also offered prizes for collections grown from their seeds, which were won by Messrs. J. Read, Thos. Smith, and Geo. Woodgate in the order named. In the other numerous classes were some good exhibits, Potatoes, Onions, and French Beans being for the season of fair merit. Messrs. J. Hudson, Read, and Smith were the principal prize-winners in this section. Amateurs and cottagers, to whom special divisions were allotted, showed much high-class produce of vegetables, fruit, and flowers.

Special prizes were given by T. Woodward, Esq., and the committee for groups of Begonias staged with Ferns or foliage plants. Some nicely arranged groups of small plants were set up, the prizewinners, in their respective orders being Messrs. C. Adkinson, R. B. Tilley, and H. Bond.

Non-competitive exhibits made a bold display. R. W. Proctor and Sons, Chesterfield, showing Roses and Dahlias, and many

varieties of Carnations. J. Cheal and Sons, Crawley, had a stand of Dahlias of the Pompon, single and Cactus sections, the latter being particularly fine. Mr. H. Deveril, Banbury, exhibited Roses and herbaceous cut flowers, having some grand Phloxes, and Messrs. Vernon and Barnard, Willaston Nurseries, Nantwich, had a stand of Dahlias. Mention should also be made of the three boxes of Roses shown by Mr. Boyes, of Derby. These were very clean and fresh in condition.

### North Middlesex Dahlia and Horticultural.

North London has had its Dahlia Show as above. Time was when Holloway, Hornsey, Crouch End, Muswell Hill, and Wood Green were purely country districts, when there were many cultivators of the Show and Fancy Dahlias spread over the district, and occasional shows were held. Then came the transformation from country to town, the upspringing of formal streets where cattle grazed and corn grew. The change in the character of the neighbourhood brought changes in pursuits also, and the culture of the Dahlia declined. But since the Cactus and Pompon varieties became so popular the denizens of the streets are taking up the cultivation of the Dahlia in their gardens, and in order to afford an opportunity for them to pit their skill as producers, a small Dahlia society was formed at Hornsey, and an exhibition was held in 1901. The society has widened its sphere of operations, and adopted a broader designation, and it is now known by the above title. It has also exchanged a small hall as its place of exhibition for the noble central hall of the Alexandra Palace, and here its second exhibition was held on the 11th and 12th inst. The growth, both in the quantity and quality of the bloom, was seen to be most satisfactory, and if only the society be managed on sound business lines there is no reason why a strong society should not be built up in this district, as it appears to be well supported locally.

Some of the trade lent a helping hand, which was much appreciated. Mr. Amos Perry, Hardy Plant Nursery, Winchmore Hill, had a large and well-arranged bank of hardy cut flowers in season. Messrs. J. Cheal and Son, Lowfield Nurseries, Crawley, sent a very fine collection of Cactus, Pompon, and single Dahlias, set up in their usual excellent style, and to two single varieties, *Lerita*, maroon crimson shading to rosy crimson, and *Snowdrop*, white, both finely formed, certificates of merit were awarded. Mr. J. T. West, Dahlia specialist, Brentwood, had a thoroughly good collection of Cactus, Pompon and Show varieties in excellent character. Messrs. W. Cutbush and Son, nurserymen, Highgate, had bunches of Cactus and other Dahlias set up in elegant bamboo stands, and Mr. E. F. Such, nurseryman, Maidenhead, had Dahlias in variety and early Chrysanthemums. To each of the foregoing a medal of the society was awarded. Mr. A. Gower, garden artist, Floral Nursery, Muswell Hill, exhibited a model garden, worked out with flowers and foliage, having in the rear a representation of the ruins of a monastery.

A few of the classes were open to all members, and this enabled some of the leading trade and amateur growers to compete. One of the latter, Mr. H. A. Needs, Horsell, Woking, took the first prize with twenty-four blooms of Cactus Dahlias shown on boards; Mr. W. Baxter, nurseryman, Woking, was second; and Mr. S. Mortimer, Swiss Nursery, Farnham, third. With twelve Show and Fancy Dahlias Mr. Mortimer came in first with very good blooms; Mr. E. Hows, Finchley, a local grower, was second. In the class for six bunches of Cactus varieties Mr. H. A. Needs was again first, staging some excellent blooms of standard varieties; Mr. S. Mortimer was a close second. In another class for a similar number of bunches Mr. W. Baxter was first and Mr. E. Hows second, both showing good blooms. Mr. Mortimer was first with six good blooms of Fancy Dahlias, and good blooms of Pompoms and also of single varieties were staged. A good number of classes were reserved for local growers, and here the competition was generally good and the quality quite satisfactory.

There were classes for hardy flowers in bunches, also for Phloxes, specimen plants, &c., and for vases of Dahlias, bouquets, epergnes, and baskets of flowers, the last a really fine feature. There were also classes for vegetables grown in the cottage and allotment gardens.

In the centre of the hall Mr. G. Hemming, the superintendent of the Park, staged a very fine group of foliage and flowering plants, and in addition a collection of hardy flowers and fine fruit of several varieties of Tomatoes; all were highly commended.

### Wolverhampton Horticultural Club.

At a well attended meeting presided over by Mr. E. Simpson (the chairman of the club), Mr. W. Gardiner, Harborne, Birmingham, in response to a special invitation, delivered a lecture entitled "Conifers and Their Cones." Much interest was evoked by the descriptive remarks of the lecturer, as well as by the large collection of branchlet cones of the *Picea*, *Pinus*, *Abies*, *Cupressus*, *Juniper*; sections obtained from some of the largest *Picea* in the country. In addition to brief descriptive references of the various species exhibited, the lecturer also remarked upon the classification of the Coniferae.

**Wirrall and Birkenhead, Sept. 10th and 11th.**

This year is the Diamond Jubilee of the society, and at its two days' show the receipts were £500 better than at any previous one. Stove and greenhouse plants were a very feeble lot, but fruit, hardy flowers, and vegetables were grand. To the ever courteous secretary, Mr. A. H. Edwardson, much credit is due. For a group of plants, Mr. H. Ogden, West Derby, showed much taste; the second prize going to Mr. Haines, gardener to E. K. Laird, Esq. The latter had the best ten stove and greenhouse plants, and other minor classes. Handsome *Coleus* came from James Birch, Esq., and both Fern classes went to Mr. C. Jones, gardener to E. Evans, Esq.

Eleven competed for the stand of cut flowers for table decoration, the award going to Mr. J. Ennion with a blending of choice Orchids, Roses, Lilies, and the necessary greenery. Fourteen put up single hand bouquets, Mr. J. Williams leading. Choice Roses were staged by Mr. S. Bell, gardener to J. N. Hodgson, Esq. The entries for Cactus and Show Dahlias were quite bewildering, the superior Lathom grower, Mr. H. Banks, winning for twelve, and six Cateus, and twelve Shows; Mr. J. Clarke taking the six class. Mr. J. Lee had a splendid collection of hardy cut flowers, bold, fresh, and of fine quality; and Miss Gaskell superb annuals.

Mr. E. A. Young had a grand dessert table of Muscat and Hamburgh Grapes, Royal George Peaches, &c. Hardy fruits were good, Mr. A. J. Oakshott leading. The competition in the Grape classes was keen, Mr. Gaunt, Mr. E. Stokes, and Mr. O. Roberts each doing well. Other winners were Mr. T. Ferguson, Mr. H. May, and Mr. Richards. The vegetable classes, both for quantity and quality, were absolutely grand, but as the kinds were unnamed, the educational value is completely lost. Messrs. E. Alty and J. H. Jones won for the collections, Mr. Millington had the lead in twelve Tomatoes (thirteen entries), and Mr. J. P. Platt, jun., for six, out of eighteen entries.

Messrs. Dicksons, Limited, Chester, had a fine stand of herbaecous plants, grain, and roots. Mr. H. Middlehurst, Liverpool, a similar stand, whilst Messrs. Garton, of Warrington, had splendid samples of Black Tartarian Oats, New Era Wheat, and Maltster Barley, for which a gold medal was awarded.—R. P. R.

**Wakefield Paxton.**

Programme of meetings for the third quarter, session 1902, which are held at the Paxton Room, Woolpacks Hotel, Westgate, each Saturday evening, at eight o'clock prompt, is as follows:—September 6.—“The Begonia” (exhibition), Mr. W. H. Vere; September 13.—“The Tomato with Specimens,” Mr. G. Dunsmore; September 20.—Vegetable Exhibition, discussion opened by Mr. J. Eastwood, Lupset; September 27.—“The Dahlia” (exhibition), Mr. J. Twigge; October 4.—Exhibition of Autumn Leaves and Fruits. Lecture by Mr. T. W. Woodhead, Technical College, Huddersfield; October 11.—“The Michaelmas Daisy and Marguerite,” Mr. J. H. Wood, Kirkstall; October 18.—“The Apple” (exhibition), Mr. T. Wilson; October 25.—“Experiments with Chemical Manures in the Kitchen Garden,” illustrated by lantern slides, Mr. F. W. E. Shrivell, Tonbridge, Kent; November 1.—“The Scattering of Seeds,” illustrated by lantern slides, Mr. H. Crowther, F.R.M.S., Leeds Museum; November 8.—“The West Country,” illustrated by lantern slides, Captain H. S. Goodyear; November 15.—Lantern lecture, Mr. F. H. Wigham; November 22.—“The Chrysanthemum” (exhibition), Mr. A. Allison; November 29.—“The Wakefield Paxton Society—Its Origin, Objects, and Aims,” Mr. H. Hazell.—T. H. MOUNTAIN, A. S. NICHOLSON, Hon. Secs.

**Ipswich Gardeners.**

At the Ipswich and District Gardeners' Association's last meeting of the session, in the Co-operative Hall, Ipswich, on September 4, Mr. A. Sowman, horticultural lecturer to the East Suffolk County Council, delivered a lecture on “The Potato: its Origin and Character.” It had been proved by experiment on all kinds of soil that the first thing towards success in the cultivation was to see that the sets were whole, in good condition, thoroughly matured, well cared for in the full light, perfectly green and hardy, and kept as cool as possible. The worst possible flavoured Potato was that grown on animal manure, whilst as to chemical manure, used in a methodical manner, it was found that the plots were not so liable to disease, and the weight of the Potatoes was more. The Potato requires four important elements, viz., potash, to make it starchy; phosphoric acid, for the production of fruitfulness; nitrates for the production of healthy foliage, and for the manufacture of food and lime, without which all chemical fertilisers would be just as useful on the roads. If they wanted to battle against Potato disease, they must devote their attention to the food of the plant. Dealing briefly with the Potato disease, Mr. Sowman said this was more particularly noticeable where the soil had been injudiciously treated with nitrates. The disease should be treated with a mixture for ten rods of a pound of copper sulphate, a pound of lime, and a pound of treacle, mixed with ten gallons of water. The cost would work out at about 15s. per acre.

# THE BEE-KEEPER.

**Wintering Bees.**

Success the following season depends upon the correct autumn preparations for winter. There is a positiveness in this assertion which claims particular attention, the reasons for which are by no means obscure. Let a colony of bees be either stimulated to breed late in the season, allowed to go into winter quarters short of food, or with stores in an unnatural position, and the certainty that this is so will be manifest. It would be easy to accumulate examples where these errors in management have been the cause of restlessness in the stocks throughout the winter and reduction in the vitality of the bees, in addition to which late breeding itself will cause abdominal distension and spring dwindling. All these hindrances to successful bee-keeping should be avoided.

In the first place, the requisites for safety during the cold months are young, vigorous queens, abundance of young bees, sufficient stores suitably located, warmth and dryness. The time to prepare for winter varies with the surrounding conditions and seasons. It is much preferable, however, to be a little too previous than too late. When the old queens are to be deposed it will be found advisable to capture the old one before the supers are removed, otherwise when all the bees from the supers are in the brood chamber the difficulty in finding her will be increased.

When the young queen has been introduced, the stock should be stimulated by feeding in order to secure the desideratum of plenty of young bees; and if the food is given a little in excess of the wants of the colony, by the time it is discontinued the stock will have stored sufficient for winter. The young bees thus obtained will not only live through the winter, but will also work on the fruit blossoms the following spring. After the middle of September an examination should be made to ascertain the amount of food present. There should be at least 30lbs sealed, which is equivalent to six frames. If there is any doubt as to the quantity feed up rapidly. The preparation of the food for autumn feeding is important. Nothing but the finest cane sugar should be used, to 10lb of which five pints of water should be added. The syrup must be medicated with naphthol beta, and on reaching boiling point should have ½oz of tartaric acid added, which will convert it into invert sugar, preventing recrystallisation, which is essential. Vinegar is occasionally recommended, but the strength varies so much that it cannot be depended upon.

A powerful colony, with plenty of room for storage, will take 10lb in a few hours if given warm at dusk. When fed in this manner there is little or no disturbance, and by the following morning there is nothing unusual visible, with the exception of a larger number of bees fanning at the entrance. Another advantage of administering food in this way is that it is so rapid that it does not stimulate the queen to more egg laying, which at such an unseasonable time would be detrimental. There should be enough bees to cover at least seven combs on both sides. Stocks which are weaker should be united after deposing the oldest queen, and any bars not covered by bees removed, and the hive reduced by dummies. When reducing the number of frames, the fact that bees require empty combs to cluster upon must not be overlooked. Those which are half filled with honey should be placed next to the cluster, the natural position of stores when the hive is in a normal condition.

The bars should then be spaced 1½ of an inch apart, so that the bees may be able to form a more compact cluster, and instead of cutting holes through the combs for winter passages, which in most cases are occupied the following season by drone comb, it is better to use “Hill's” device, or place strips of wood about ½in thick on the top of the frames. The extra quilts should consist of bags, or the admirable protection suggested by Mr. Cheshire, consisting of a shallow box or super the same size as the brood chamber, with a loose cloth bottom filled with cork dust. The latter may be procured from any fruiterer who sells foreign Grapes. This forms a non-conducting quilt, which allows free ventilation without draught, while retaining the heat of the cluster. If the cork dust gets wet it will not rot like chaff or other vegetable matter.

Entrances should be opened 1in for each bar of bees, as in performing respiration bees consume a certain amount of oxygen, and to obtain this, expel the carbonic acid gas, and maintain the temperature of the cluster, entails a greater expenditure of energy when there is an insufficient entrance. This also serves to emphasise the wisdom of evaporative efficiency in quilts. The relative value of the different materials for this purpose has been a fruitful subject of discussion, and it appears that the superiority of felt is due to the fact that it entraps the air which it contains in a better manner than any other material commonly used, and it is the non-conducting properties of confined air upon which the efficiency of the quilt depends. The perfect quilt is sufficiently porous to permit slow upward ventilation without draught.

Inability to secure this while using linoleum constitutes one of its greatest disadvantages. The entrance being at the bottom makes

it impossible for the vitiated air to escape, and it has consequently to be driven out by the bees. With plenty of air underneath, suitable warm covering above, a waterproof roof, and the requisite conditions previously mentioned, stocks will require nothing more till March, except an occasional examination to ascertain if the quilts are dry.—E. E., Sandbach.

### Orchids—The Week's Cultural Notes.

Day after day of dull and wet weather is not at all to the liking of heat-loving Orchids, such as *Phalenopsis*, for no matter how good the heating arrangements, nothing takes the place of sun as a quickening buoyant agent to the atmosphere. We can only do our best, and that consists in keeping the glass scrupulously clean inside and out, and allowing sufficient heat on the pipes to enable the ventilators to be opened daily. The plants themselves, too, must be frequently sponged to remove accumulations of dust and enable the sensitive leaves to carry out their proper functions.

The roots must not be disturbed now further than to remove any of the surface moss that has grown too freely during the summer, and will hold too much moisture in suspension later on in the season. This is most safely accomplished by the hand. Some growers use scissors to clip it off, but in case of a root pushing upward, as often happens, this would be likely to be severed, and a check to the plant would ensue. In other cases the moss may be dead or decaying, and here it should be removed and its place filled with new.

The Mexican *Laelias* are many of them growing freely and throwing up their spikes. Every ray of sun possible should be allowed to reach them. In small collections where only a few plants of each species are grown these may be taken to the Cattleya house and suspended in the lightest part of it close to the glass, but when a house or compartment is set aside for their reception then the best must be done by elevating the specimens on pots inverted, and allowing all the room possible between them. *L. majalis* will by now have had a good turn in the open air, and should be brought in and hung up in the sunniest position and kept well on the dry side.

*L. autumnalis* and *L. anceps* are very similar plants in appearance and requirements; they are both needing moisture in medium supply, and considerable watchfulness must be practised, else slugs and small snails will make havoc of the spikes. A more difficult plant to manage is the refined and charming *L. albidula*. In treating this Orchid I have always found it best to let it have its head, and not attempt either to force it to grow or to rest when its inclinations seem to run in the opposite direction.—H. R. R.

### Hardy Fruit Garden.

**OUTDOOR VINES.**—Vines on outdoor walls and trellises that have a full crop of bunches should not be allowed to have such an amount of crowded growth as will exclude light and air from the interior, these conditions being necessary, not only for the complete ripening and finishing of the crop, but also for the ripening of the wood. Black Grapes need not be fully exposed to the sun, as the berries colour up better when partially shaded, but white Grapes require full exposure, and this should be secured to them. A little manipulation of the growths and the tying back of any obstructing leaves will afford the exposure necessary. Young canes necessary for next year's cropping should be laid in, and very little superfluous wood ought to be allowed. As a help towards finishing off the crop give a little extra sustenance to the roots, weak liquid manure, guano, scot water, or artificial manure providing suitable food. Should the border prove to be very dry, it is desirable to moisten it thoroughly with clear water. The sudden moistening, however, of a dry border may cause the berries to crack owing to the increased flow of the sap. This emphasises the importance of maintaining regular moisture throughout the growing season. A light mulching of manure is of great assistance in maintaining equable moist conditions.

**BLACKBERRIES.**—The new canes have grown vigorously, and of considerable length, but only the strongest should be retained, spacing them out on the trellis in order that they may become thoroughly ripened. When the crop of fruit has all been gathered, there is no further need of the bearing growths, and they may, therefore, be cut out, which will afford additional space. The extreme tips of the long growths can be removed. Further

shortening should be carried out in winter, when the canes may be pruned back to ripe parts.

**APPLES AND PEARS.**—The whole of the early, and many of the midseason varieties of Apples and Pears may be completed gathering now. Blustering winds of extra force often occur about this period, and the result is seen in the wholesale fall of varieties just commencing to ripen. Fruit which falls prematurely owing to grubs in them, or fallen fruit of any description, should be picked up, utilising the best, and destroying the rest. Fruit in store must be looked over frequently. Apparently good fruit is found commencing to decay, and requires removal before it contaminates other specimens. A few samples of bruised fruit may accidentally have been introduced, and should not remain.—EAST KENT.

### Fruit Forcing.

**VINES.—MIDSEASON HOUSES.**—Where the Grapes are still hanging careful attention must be given to the ventilation, a little air being admitted constantly, and in cold damp weather a gentle warmth in the hot-water pipes, so as to ensure a circulation, or prevent the atmosphere becoming stagnant and moisture being deposited on the berries. When the atmosphere is properly aerified Grapes will become raisins before they will decay, provided care be taken to promptly remove any berries that show indications of decomposition. A moderately moist condition at the roots is necessary to preserve the plumpness of the berries, and will not do any harm while the Vines have leaves in a more or less active state. Laterals should be kept well in hand, and even reduced when growth ceases.

Vines, from which the Grapes have been cut may now be divested of their laterals down to the principal buds, even shortening the bearing shoots to a joint or two above the pruning buds, which will tend to plump the basal ones, and the storing of matter of a nutrient nature in the adjacent wood. A free circulation of air is necessary, and in the case of young Vines, or where there is the least doubt about the thorough ripening of the growths, fire heat will be necessary. When indications of the maturing of the foliage is manifest, top-dressing is best effected, or even earlier when the Vines are weak and unsatisfactory. If the roots are active at the surface, in the old mulching or top-dressing, it will only be necessary to remove the loose material and give a top-dressing of turfy loam with a fifth of sweetened manure and a sprinkling of bonemeal two parts, and one of sulphate of potash, mixed, and about 4oz per square yard, or the advertised fertilisers will answer a similar purpose, that of supplying phosphatic and potassic matter to the soil. If the roots have not penetrated the mulching, remove the soil down to them and supply fresh compost, but not covering them deeply, 2 or 3in is sufficient, taking the opportunity to lift any that are deep and lay them in fresh material nearer the surface. A moderate watering will be needed in the case of inside borders, but outside ones will rarely need it at this season, and after they have had the benefit of the October rains a covering of leaves and a little litter over them will be all that is needed to exclude frost, which is important for Vines started while severe weather prevails. In the case of borders only partly made, a breadth of 2ft may be added to the front, choosing dry weather for the operation and putting the materials together firmly.

**YOUNG VINES.**—Those planted this spring or early in the summer will need every encouragement in keeping the foliage clean and healthy, also keep the laterals away from the principal leaves in order that they may have due exposure to the air and light, especially those at the base of the canes, so that the buds to which the Vines are to be pruned may be thoroughly matured, and the wood well ripened. In order to insure the ripening of the wood maintain a genial warmth in the hot-water pipes by day with moderate ventilation, and throw the house open at night, except when frost prevails.—ST. ALBANS.

### Trade Notes.

#### The Bulb Catalogues.

Messrs. Ware, Limited, of Hale Farm Nurseries, Feltham, have issued their autumn bulb and plant catalogue, which is found to be replete with good lists. Their tuberous *Begonias* at Bexley Heath are in full bloom, and well worthy of a visit.

Once again our pile of new bulb catalogues has risen to over a foot in height on the shelf assigned to them. First to hand came Ant. Roozen and Sons' (general agents for Great Britain, Messrs. Mertens and Co., 3, Cross Lane, St. Mary-at-Hill, London, E.C.), which we think is a useful catalogue for all gardeners, containing as it does important cultural notes, with good lists and descriptions, not only of Dutch, but also of Cape bulbs. Some hardy herbaceous plants are also included. Of home bulb lists, those of Messrs. Sutton, Veitch, Webb, Clibran, Dicksons, Limited, Barr and Sons, Pearsons, and R. H. Bath, Limited, are well arranged and thoroughly representative. Messrs. Hogg and Robertson's is very interesting, and E. P. Dixon and Sons, of Hull, include coloured illustrations in their list.

# TO CORRESPONDENTS

\* \* All correspondence relating to editorial matters should be directed to "THE EDITOR," 12, Mitre Court Chambers, Fleet Street, London, E.C. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense.

THE FRUIT MANUAL (T. M.).—Dr. Hogg's "Fruit Manual" has been for long out of print.

MONTHLY ROSES (F. P.).—The old Monthly Rose belongs to the China class, and is known as Old Blush or Common China. Of this class Cramoisie Supérieure, crimson; Duchess, white; Fabvier, scarlet; Mrs. Bosanquet, waxy flesh; and Old Crimson or Dark China are fine for massing or beds.

LEAF-SPOT ON TOMATOES (Idem).—The best remedy for Tomato leaf-rust fungus, *Clado-perium fulvum*, is to maintain a gentle warmth in the hot-water pipes, admit air freely, and run up in the afternoon to a temperature of 100deg to 110deg for an hour or two, repeating this occasionally. Badly infested leaves should be removed and burnt, and the plants dusted with a fungicide in powder, such as the advertised, or should be, anti-blight, fostite, and strawsonite. As a liquid for spraying, Messrs. Wood and Sons' Veltha emulsion may be mentioned as effective, spraying upwards as well as over the foliage.

PRESERVING FRENCH BEANS AND PEAS FOR WINTER USE (W. E.).—French Beans may be preserved by collecting them when quite dry and of size fit for use, placing in glazed earthenware jars in layers alternately with salt, first placing in a layer of pods, then sprinkling on salt enough to cover them, and so on until the jar is full, when place on the lid tightly. When required for use the pods should be steeped in water overnight to abstract some of the salt. Peas are bottled, and to give colour are treated with sulphate of copper. We do not know the exact process: perhaps some correspondent will oblige with particulars.

RED SPOTS ON ZONAL PELARGONIUM CUTTING (C. N.).—Though we examined the red spots very carefully we found no trace in the tissue of the mycelial hyphæ, or externally any outgrowths of a parasitic fungus. The work appears that of the leaf-rust mite, *Tarsonymus Gerani*, which by its bites and mode of life of larvæ, is very pernicious, crippling the growth, and rendering these stunted and, as you say, brittle. The best hindrance to the pest is spraying or dipping in tobacco water, 1oz of the strongest shag tobacco being placed in a vessel and to remain until cool, then straining and using for spraying or dipping.

ARTIFICIAL MANURE FOR ORCHARD IN GRASS (Twenty Years' Subscriber).—As you cannot continue the depasturing and well-feeding of sheep, or even that of keeping fowls and pigs in the orchard, you may prepare a mixture as follows:—Nitrate of soda, 1½ part; dissolved bones, 6 parts; high grade mineral superphosphate, 3½ parts; muriate of potash, 3 parts; kainit, 4 parts; wood ashes, 2 parts; mixed. This contains about 1.9 per cent. of nitrogen, 8 per cent. of phosphoric acid, and 11 per cent. of potash. It may be applied in the autumn at the rate of 5 cwt per acre, 3½lb per rod, or not later than February, as soon as the ground is drained. Autumn, however, is the preferable time. Another simple preparation is composed of equal parts dissolved bones and kainit, applying 3½lb of the mixture in the autumn, and in spring, when the buds commence swelling, supply 1½lb per rod of finely crushed nitrate of soda, or preferably, as the ground is a stiff yellow loam, sulphate of ammonia.

MALLOW STEM DISEASED (F. P.).—The Mallow stem is affected by the *Sclerotium* disease, a parasitic fungus named *Sclerotinia sclerotiorum*. The stem is the part most frequently attacked, the disease first showing itself just above the ground-line as a delicate white mould encircling the stem. The mycelium also penetrates into the interior, and gradually extends upwards. Finally, the stem becomes dry and brittle, and falls down. If such diseased stem is cut open, a considerable number of black sclerotia of very variable size and shape are met with in the pith, surrounded by mycelium, and they often form on the outside of the stem. These live in the ground until the following spring, when they give origin to several funnel-shaped ascophores, from which the spores produced in asci are ejected at maturity. Diseased stems should be collected and burned, and where the disease has existed before, the ground should be given a liberal dressing of quicklime, avoiding the use of fresh manure, especially on the surface of the soil.

ARE ALL LARGE ROUND GOURDS EDIBLE? (F. J.).—Most of the large Gourds or Pumpkins are edible, such as the Large Green, Large Yellow, Mammoth, and Ohio Squash. The other, or Ornamental Gourds, are not edible, being grown for decorative purposes from their peculiar and varied forms, also colouring of the ripe fruits.

VAPORISING WITH XL ALL COMPOUND FOR THE DESTRUCTION OF RED SPIDER (A. J.).—Your experiment is very interesting, the red spider being certainly still alive on the Croton leaf, hence vaporisation with nicotine compound evidently has no material prejudicial effect on this pest. The communication is also valuable as showing the effect of nicotine vapour on the fronds of Ferns, Pteris, and Adiantums.

DISEASED VIOLET LEAVES (H. S.).—The leaves are affected by the Violet leaf-spot fungus, *Cercospora violæ*, which causes dry pallid spots to form on the leaves of *Viola odorata* and the varieties of Sweet Violet, and often prove troublesome, if not wholly destructive, to the foliage in the late summer and autumn months, both outdoors and under glass. It begins as a very minute speck and rapidly increases in size, forming large blotches, and frequently the spots run into each other, involving a large portion, if not the whole, of a leaf. The disease spreads very rapidly, so that there is scarcely a healthy leaf left. It is most prevalent in cold and wet seasons. Removal and burning of the affected leaves check the disease somewhat, but as the spores are produced whilst there is the merest speck visible to the naked eye, this does not wholly arrest the disease. Spraying with ammoniacal solution of copper carbonate may protect the young leaves from attack, but fungicides have not given good results as regards prevention and suppression of this pest. Growing thinly and allowing the plants plenty of air and light is the best means of avoiding the disease. This will be accorded to some extent by removing infected leaves.

NAMES OF FRUIT.—Correspondents whose queries are unanswered in the present issue are respectfully requested to consult the following number. (A. W.).—The Apple is Yorkshire Beauty, syn. Red Hawthornden. (P. A. T.).—The Grapes are, 1. West's St. Peter's; 2. Buckland Sweetwater; 3. Golden Queen.

NAMES OF PLANTS.—Correspondents whose queries are unanswered in the present issue are respectfully requested to consult the following number. (Nemo).—1. *Celsia* sp.; 2. *Enonymus japonicus albo-marginatis*; 3. *E. j. aureo-marginatis*. (Water Weed).—Sorry to have held the names a week; 1. *Potamogeton densus*; 2. *Myriophyllum verticillatum*; 3. *Ranunculus heterophyllus*; 4. *Clara fragilis*. (Oxon Subscriber).—1. *Spiræa japonica*; 2. *Impatiens Roylei*; 3. *Polygonum cuspidatum*. (J. C. Subscriber).—No. 1, *Odontoglossum Andersonianum*; 2. *Veronica virginica*; 3. *Stachys grandiflora rosea*; 4. *Lythrum Salicaria*, a handsome native plant. (C. T. G.).—*Galega officinalis*. (F. W.).—*Miltonia Clowesi*. (P. A. T.).—Your Conifers next week. Please only to send one leaf at a time in any one week, else there may be confusion.

## Trade Catalogues Received.

Harrison and Sons, Seedgrowers and Merchants, Market Place Leicester.—*Bulbs and Roots*.  
Pope and Son, King's Norton, Birmingham.—*Bulbs*.  
Thomas S. Ware, Ltd., Hale Farm Nurseries, Feltham, Middlesex.—*Bulbs and Plants*.

## Meteorological Observations at Chiswick.

Taken in the Royal Horticultural Society's Gardens at Chiswick, height above sea level 24 feet.

The weather for the most part has been dull and cool. A thunder-storm occurred on the 10th, and a very heavy fall of rain on the 11th.

## To the North.

It is not very often we give ourselves the pleasure of an outing at harvest time, but business called us North (how the North does call us of northern breeding!), and the journey has been one of interest and profit. From the Midlands to canny Newcastle is rather like ascending high hills; the vegetation is in zones of progress; imperceptibly you pass from one to another. The signs are the backwardness or difference of the crops. The best crops we saw were to be found in the rich alluvial valley of the Trent, and, taking into consideration the heavy rainfall, we were astonished to see the Barley so bright and clean. Funny term to apply, "clean," but there is no other word to indicate the pleasing appearance of the straw. What we could not see, but what we heard of, was the sad damage the crops had sustained during the heavy gales of September 3, when the wind was quite equinoctial in its character. "Necked Barley" means serious loss, for the necked heads are among the best and most upright. There are certain classes of Barley that are liable to this danger, and unfortunately they also happen to be among those which are essentially maltsters' varieties.

Not only is there sad havoc among necked Barley, but Oats suffered to a great extent, the upper grains being completely knocked out, as though with a perfect threshing machine. But there's a silver lining to every cloud; there is no drying agency like wind, and the fields were very bad; the going for reapers must have been hard, and then, again, this year "seeds," i.e., young Clovers, are superabundant, and it has been a problem how to get those seeds dry and fit to lead by the time the corn was ready. It seemed such a risky business, and so provoking, that the Barley, the valuable part, stood risk of much weathering, while the butt end of the sheaf dried. We saw several good upstanding fields of Rivett's Wheat, grown, no doubt, not for the grain as much as for the valuable straw, which is of such excellent quality, and so in demand for thatching purposes and the covering down of the Potato pies. The fault of Rivett is this, it is always so backward in ripening; but, late as the season is, perhaps this time that is not altogether a drawback, as the wind, and now the brilliant sunshine, will cause all the other varieties to be ready at once, and as it is very certain the farmer and his forces cannot be in two places at once, it is well there is one crop, at least, that can wait without taking harm.

Never have we seen fuller Potato rows; but, as a travelling companion remarked, as we flew past the fields: "They've got it!" There was a note of satisfaction in his tone not understandable of the outsider. The outsider saw a brown, withered appearance, which did not look promising. The grower knew that meant disease, and in a disease year prices always rise. There is such a thing as having too good a crop; a crop which causes prices to fall to almost (or, indeed, to) vanishing point, a point where there are no returns for the poor grower. We have still to hear of that railway company which reduced its tariff on account of an overstocked market. We were not able to say whether any of the fields we saw had at an earlier period been sprayed, but we should very much like to know how those plots fared that had received a dressing, say, twice or three times.

We saw one unusual industry, and that was the British Peat Moss Company. We believe that this industry is responsible for the introduction of a foreign element. There are Dutch colonies to be found where this peat moss abounds, and land that so long has laid waste is now returning to its owners a very comfortable provision. Certainly peat moss litter is growing in favour, and only wants to be better known to be appreciated. It is funny stuff to look at, but is eminently adapted for bedding purposes, and especially under those conditions where much stock has to

be kept in limited areas. It is antiseptic, and therefore is a valuable agent in minimising nasty smells.

Taking the country throughout, the Turnip and Swede prices were excellent. We saw one field in Durham which was patchy, and we were near enough to see that in places the plants were dying out. Certainly it could not be from lack of moisture. Query: Wireworm? What struck us most was the vivid green of the grass fields and great quantity of "good meat" still remaining; but, and we could not account for it, we noticed great dearth of stock. Where is the stock? They certainly were not grazing, and the state of the pastures presented no solution. We fancy we can give a pretty good guess at the reason. What could possibly be spared have gone to pay harvest wages and midsummer bills. The haystacks are abundant, and, let us hope, good.

There is no doubt about it, that with the present delightful change in the weather the northern farmer will this year stand a better chance of a good harvest time. Then, again, sometimes it is a good thing to be backward. There can this season be no reason why the young seeds should be grazed, and that will be a distinct gain next spring.

With the end of the summer comes the dwindling record of shows, and to take their place we find plenty of ram sales and sales of store sheep, and it may possibly be that the fact of scarcity of money among farmers will affect these sales adversely. The same applies to the dispersal of various shorthorn herds and shire studs. Farmers are not backward, as a rule, in securing good sires, but they are blamed, and not without reason, for neglecting to look more closely after the qualities of the stock on the female side. They are adverse to the purchase, say, of promising young heifers of a good milking strain, whereas a little outlay in this direction might prove in the long run a veritable gold mine. Remember, in breeding good antecedents on both sides tell. There is now a distinct movement among dairy cattle; the milking herd is in process of being "graded up." That has to be done if we are to produce milk to meet the requirements of the new regulations.

As we write the auctioneer's hammer falls at Gravel Hill, Cambridge, and Mr. Fred Crisp's shires are under dispersal. There will be a unique chance for those who wish for some really good blood, and we shall mark with interest the ultimate fate of the two daughters of that champion mare, Starlight, that was purchased for over 900 guineas from the stud of R. N. Sutton-Nelthorpe, of Scawby, in the county of Lincs.

N.B.—We have just heard from a friend of a field of Barley near Dunbar where, to the naked eye, there is not a single head left; all fallen before the terrific gale of September 3.

## Work on the Home Farm.

Rain again to-day! But neither men nor horses will be averse to a rest, whatever the farmers' feelings may be. Great progress has been made with the reaping, and a stack or two here and there denote that we have some early birds amongst us. Barley being more forward than Wheat is nearly all in stook, and it is wonderful how well the machines have cut it. The old rake machines have done a good deal of the work, but where binders have been requisitioned they have worked well. They certainly clean all up better than the other machines, but the straw-bound sheaves are far more quickly in condition for leading. Stackyards will be very full: the crops are bulking up heavier even than we expected. Farmers will be wise to stack a portion in the fields. The stacks are quicker in attaining thrashing condition and in less danger from fire than when packed closely together.

We wonder that insurance companies do not make stipulations against the close concentration of large quantities of corn stacks. They object to taking risks on stackyards which are near lines of railway, but we have many times seen thrashing engines set between high unthatched stacks in hot, dry weather, when a spark would set fire to them, and there have been a score or more by stacks closely adjoining. Farmers insure their corn in stack, and forget that the insurance can only be partial. However well the insurance company treats him he is sure to be a loser, and often a considerable one, and it is noticeable that a farmer who has had one serious fire never afterwards is found to put many (corn rick) eggs into one (yard) basket.

The dry week did much to dry up the dead Potato haulm and retard the spread of disease, and we hope the rain will not give it new life. The blight on the leaf is very general, especially so with regard to Up-to-Dates. Professor Maercker is the variety which keeps the greenest.

*Journal of Horticulture.*  
THURSDAY, SEPTEMBER 25, 1902.

**Some Shattered Idols.**

NOT only from a horticultural standpoint, but an agricultural, commercial, and domestic one, there has been many, and, in some instances, grievous shattering of the idols set up in the minds of thousands, nay, millions of British minds this year, that to which particular and special thoughts are turned being the Coronation collapse on the great and memorable day of June last. Though in the great commercial world every unit suffered a proportionate loss, that affecting horticulture was an immeasurable one, for vast preparations were made by the forced advance on the one hand, and the retarded effort on the other, all culminating in wholesale loss, because so much of the gardeners' produce is of perishable nature, and so entirely opposed to other wares that may be stored for future contingencies. The great flower and fruit emporiums around London, and many hundreds scattered over the whole kingdom, were all bent on providing for the great Coronation festival, and all had hopes of reaping a reward for labour proportionate to the investment indulged in; but to what extent was the shattering of the idols and the hopes of individuals is known, probably, best only to the unit severally of the great mass of providers.

These thoughts, though of the now remote past, still run concurrent with those of the present time, for if the Coronation collapse was the only failing of the season it might sooner have been forgotten. Such, however, is not the case, for as the weeks and months have come and gone, dating from the early days of the year, there has been a much greater preponderance of ills than triumphs. The market and flower show speak eloquently in this language of disappointment. In every

READERS are requested to send notices of Gardening Appointments or Notes of Horticultural Interest, intimations of Meetings, Queries, and all Articles for Publication, officially to "THE EDITOR," at 12, Mitre Court Chambers, Fleet Street, London, E.C., and to no other person and to no other address.

conference between gardeners, which the annual flower show bring together, it may be at the Drill Hall, at Shrewsbury, or the remotest village in the country, there are sure to be the same topics raised when a quorum of gardeners, amateur or professional, meet, and individual troubles met and surmounted in their many forms are related as an appeasement and solace offered and accepted from one to another. There is a great and mutual sympathy existing among horticulturists as a body throughout the many sections in which it is divided, and this mutuality has been a great power in dealing with the troubles of the year.

Though the winter was cheerless and cold, and the rainfall much below the average, fruit trees of all kinds made a wonderful effort to do their best, and, indeed, the gardener's hopes were raised to a high concert pitch by the wealth and vigour of almost every kind of tree and plant. When one considers the droughty state of the soil last year, it was not less than marvellous that the universal tree life should have responded so well to the trying exigencies of weather. But so it was, and but for ill winds which, contrary to proverb, have blown no one good, there were splendid prospects held out from the garden and field almost everywhere. The great staple fruit of the British orchard made country drives and railway journeys intensely pleasant by their bounteous blossom; Pears, Cherries, and Plums were not less remarkable in the outburst of their floral spring dress. King Frost, and the not less powerful factor, "blight," have both asserted their prowess in a most determined manner. One advanced gardener was overheard to say that instances were not wanting where the air of fruit plantations was simply made odorous with quassia and its allies, and while he yet diligently applied it himself, his trees were not able to make any headway, nor did his effort combat the virulent enemy. He then turned his thoughts to an antidote of another kind, one applied to the roots instead of the heads of his trees—nitrate of soda. This had a marked effect in producing growth, and whether the growth advanced by this stimulant was too fast for the depredators to hold in hand, or the sap promoted by the action of the soda was too strong in flavour, is an item of theory on which thoughts may vary. Whatever its basis may be, certainly results were assuring, not so much for the present as the future crops in prospect. No doubt there are thousands of instances where trees, garden and orchard, are in a sorry plight, due to the persistent attacks of insect life, and Apples in particular have been hard punished. Plums, another great market commodity, were full of promise as regards flower, the trees healthy, and the blossom strong. The cold winds prevailing at the time, however, contributed more to their collapse than actual frost. One instance of the shortness of the crop in a remote country district occurs to me as I write: A grower accustomed to the gathering and sale of scores of sacks of Plums this year bewails a crop of 15lb.

In regard to Strawberries, who among the hosts of private and market growers can record an absolute triumph without at some period of the season a disturbed state of mind consequent on frost, cold winds and late season? The great bulk of the nation's crop was matured almost within the space of a fortnight's duration, early and late districts being brought into conflict, and a great depression of price was created by the fact of foreign fruit being ripe and sold at the same time. Truly there was a great and very severe shattering of the nerves of the grower, when comparisons were made with the wealth of his crop and the income derived therefrom.

Another great industry in the market world, the growth of Tomatoes and Cucumbers, finds records which are distinctly unfavourable. There were extremely bad times for setting of the fruits of these under glass, and outdoors they are late, and threatened with wholesale destruction by disease attack. Cucumbers have been erratic, mysterious diseases and collapse have been very rife. The cold and sunless season has contributed to much of this, and one almost wonders, when reflection is made on the absent sunshine, that vegetation has responded so well as it has done.

There may or there may not, be a shred of consolation in the fact that these alternate elevations and depressions of spirit have prevailed universally. In some seasons one hears of bounteous crops in one county or district, while in others a frost visitation, or some other local terror, annihilated both hope and prospect, which up to a certain period had been so favourable. This season the whole community have occasion for mutual sympathy, as it is not a common experience to find instances of the exemption of trouble in

some form or other. Thus the man of commerce, the professional, and the cottage gardener find themselves on the same platform, and are in mutual agreement as to the results of his season's labour and corresponding returns. It might be possible to fill a great space by the recounting of endless troubles and losses consequent on the trying season; one of which it is very difficult to match the record, for, from its early inception, it has dealt in reverse rather than favourable traits, and who can say what are the winter's prospects in regard to Potatoes and the corn harvests? At the time of writing, certainly, idols of the past are not advancing towards that desirable, rosy-hued ideal. Hope has always been, and still remains, a great factor in the horticultural mind, though often so hopelessly shattered.—W. STRUGNELL.

## Town Trees.

(Continued from page 236.)

### Species of Ash.

Common Ash (*Fraxinus excelsior*) often springs up from seeds in town backyards, and even obtains a footing on old walls, often giving rise to the thought, How do the seeds get there? The seedlings grow with astonishing vigour, and battle bravely and successfully with the impurities of the atmosphere and stifling heat of the confined spaces. The saplings are very healthy, and do splendidly until they reach the height of the first floor windows, or even higher. For some reason—perhaps they think their work is done—they then begin to go back, "smaller by degrees and beautifully less," age fast, lose leaves early in late summer, and are now, as the ladies say, not nice to look at on the trees nor tread upon on blue bricks. An aged town Ash tree, with its stem swollen yet not large in size, holed by black fungus, and tops dying back, with excrescences on the twigs and limbs, even holes in the trunks, of which billybiters and high-up starlings take advantage for nesting, is about one of the wierdest things in Nature.

The weeping Ash (*F. e. pendula*) never plays such like pranks, and is nowhere as regards affording delight to lovers of the grotesque. The variegated Ashes appear all too tender for windy places, though this certainly does not arise from dislike of smoke and fumes, as the disguised chlorophyll appears to confer resistant power on the possessors.

The Manna, or flowering Ash (*F. ornatus*) has borne the drought and heat more satisfactorily than the common Ash, excepting young trees of the latter, and as a low tree has claims on the town planter, especially the country, far too little requisitioned. Its greenish-white catkin-like clustered flowers are very beautiful, and the whole tree handsome. The drought and heat has been too much for it this season in densely packed places, the foliage being the reverse of handsome at the beginning of September.

Of the other Ashes, the green Ash (*F. viridis*) has still bright green leafage, not only in country towns, but in very smoky districts. It and the black Ash (*F. sambueifolia*) form fine heads, half balls, as standards, but with broad tops, and are more leafy than the common Ash. These species appear not to suffer from the vegetable and animal parasites which beset our native one.

### The Stately Beech.

Coming to the hard-leaved trees, the Beech (*Fagus sylvatica*) has contracted less Beech suckers (*Chermes fagi*) than usual, which often causes the leaves to have a very unsightly appearance and fall in showers during September. The purple-leaved Beech (*F. s. purpurea*), though liable, is less subject to fly attack than the common, but both are losing the leafage rapidly. The common Beech makes a good screen or high hedge in smoky towns, and thrives according to the winter, not summer, cutting in. But of all the Beeches for smoky towns, and even exposed situations, the copper Beech (*F. s. cuprea*) is the cleanest, and stands heat-reflected influences the best, the foliage not giving way until autumn is well advanced, especially on chalky soils. Still, not any of the Beeches are commendable for street planting as their roots run on the surface, thus rendering the ground very uneven.

The Spanish Chestnut (*Castanea sativa* or *vesea* or *vulgaris*) grows slowly at start, and surely, particularly on cold, heavy soils, and its foliage resists reflected heat influences remarkably well. The prickly involucre which enclose the fruits or nuts, and the rootstock swelling out are fatal objections to the Sweet Chestnut as a town street tree.—G. A.

(To be concluded.)

**Cattleya Luddemanniana alba.**

This chastely beautiful variety of the handsome *Cattleya Luddemanniana* was first exhibited at a meeting of the Royal Horticultural Society on September 12, 1899, from E. Duckworth, Esq. (gardener, Mr. W. H. Tindale), Shaw Hall, Flixton, when the First Class Certificate of the Orchid Committee was accorded. It is a true albino, inasmuch as it is wholly glistening white, save for a touch of soft yellow on the side lobes of the throat. Our illustration shows a flower of the natural size. The variety does not seem to be yet in commerce.

**Dendrobiums: Their Growth and Culture.**

(Continued from page 193.)

The Australian section contains some truly grand species. What would our Orchid houses be in autumn without the many gorgeous varieties of *D. Phalaenopsis*? So indispensable has this become that we wonder how we got along without it some few years ago before its reintroduction. And there are many others almost equally beautiful. All like a hot, moist, and light house, with hardly any shading, and they must be allowed to take their own way with regard to rest. If a plant commences to grow, even if it is in the depth of winter, it will be useless to try and prevent it, for such a proceeding will only weaken the plant. But when they start away in bright summer weather and rapidly swell up they are sure to be more satisfactory. Endeavour, then, by all reasonable means to keep them dormant until the conditions are suitable, and then let them grow as rapidly as possible. In the following list many fine species are included, but others are left out for reasons that are obvious. These will make an extremely interesting collection.

*D. aggregatum* is a close growing little evergreen species, bearing loose racemes of pretty primrose yellow flowers that change with age to a deeper tint. I have had nice specimens of this on rough blocks of Apple or Pear wood, where they have a pretty and natural effect, while the roughness of the bark suits the roots better than any description of made-up compost. It is an old inhabitant of our houses, having flowered in this country as far back as 1834. It is a native of India and China. *D. albo-sanguineum* is a larger and far more showy plant, introduced in 1851 from Moulmein. It has short erect leafy pseudo-bulbs, from near the tops of which the two or three-flowered peduncles issue. The flowers are very pale yellow, with two large crimson purple blotches in the centre of each, and nearly 3 in across, so that a well flowered specimen makes a very fine display. Basket treatment should be given it in the warmest house.

*D. aureum* is a well known and very beautiful species, sometimes met with under the name of *D. heterocarpum*. It has erect shortish stems and bears pretty creamy yellow flowers, with a few streaks of purple about the lip. Although this species is

not especially showy, it is one of the parents of many fine hybrids. Being widely distributed, naturally the flowers vary a good deal in colour, and several varieties are described. One of the best of these is *aurantiacum*, having flowers of a rich orange yellow. The treatment advised for the deciduous species will suit this well. *D. barbatulum* is not a showy plant, but bears pretty white flowers in crowded racemes; it is a native of southern Hindostan. *D. Bensoniae* is a very beautiful member of the deciduous group, having tallish erect stems, that in their season are wreathed with the pretty white flowers, spotted with maroon and orange. It is a native of British Burmah, where it was discovered by Colouel Benson, and sent home to Messrs. Veitch, of Chelsea, in 1866.

*D. bigibbum*, a member of the Australian section, is one of the finest species in the genus. It has tall, cylindrical stems, from the upper portions of which proceed the beautiful racemes of bright magenta purple flowers. It was discovered in the early part of the nineteenth century, having flowered at Kew in 1824, but it did not come into general cultivation until many years afterwards. It flowers in autumn. *D. Boxalli* is a very beautiful species sent home by the energetic collector whose name it bears in 1873, when he was collecting for Messrs. Hugh Low and Co. It has slender pendulous pseudo-bulbs or stems, along which the flowers occur in racemes of two or three, making a delighted show when in full flower. It must be treated as advised for the deciduous section, and is a native of Burmah.

A very striking species, quite distinct from all others, is *D. Brymerianum*, the flowers of which are deep golden yellow, the front of the lip being cut up into a deep hairy fringe. This remarkable species is a native of Burmah, and although of almost evergreen character, requires a thorough rest in winter, with only sufficient moisture to keep the stems from shrivelling. *D. capillipes* is a small growing plant, bearing short racemes of bright yellow blossom, something after the manner of *D. aggregatum*, and it thrives under the same conditions—H. R. R.

(To be continued.)

**Week's Cultural Notes**

The cool house is a very interesting structure just now, not on account of the number of flowers, but the growth that the plants are making. As I noted recently, the autumn is the time for giving new material to many of the *Odontoglossums*, *Oncidiums*, and some of the *Masdevallias*, all denizens

of the cool house, and where much of this repotting has been done it will be wise to allow a slightly closer atmosphere to enable the plants to take a fresh hold on the compost without difficulty. It must not be overdone, for no Orchid, and especially no *Odontoglossum*, can live for long in a close structure. The air they are so bountifully supplied with in their mountain homes must always be allowed in their confinement to the glass structures in which we grow them, but moister and closer conditions for a week or two after disturbance can do no harm.

On occasion the fact of disturbing the roots will cause a flower spike to appear in the centre of the new growth, and allowing this to develop and carry its flowers till they fade has been the ruin of many semi-established specimens. If the roots are running freely, and the plant shows no sign of distress, then by all means let it flower; but if, on the other hand, as often happens, the plant already shows signs of shrivelling when the tip of the flower spike appears, then nip that spike before it reaches the bud, or probably you will have to bemoan the loss of your plant.

Other plants come away with very large healthy growths, the roots revelling in the new compost, greedily sucking up frequently

**Cattleya Luddemanniana alba.**

supplied moisture, and growing like Leeks, to use a common phrase. These are they that delight the true practical grower. He knows that, although he may have longer to wait for his flowers, yet when they do appear the plants will have the requisite stamina to bring these to perfection without weakening themselves for the present or any future occasion. When the leaves are hard and rustling to the touch, when they spring back to their position on being brushed by the hand, they are all right; it is the flabby looking soft foliage that drops off wholesale in a dark dull winter, and is the sure forerunner of spot and other evils that attack cool Orchids. Sweet compost, healthy roots, and abundant air supplies conduce to the former results, and now is the time, by judicious ventilation and treatment, to strengthen and invigorate the plants against the coming winter.—H. R. R.

## APPLE AND PEAR ILLUSTRATIONS.

On page 285 are figures of (1) Apple Allington Pippin, one of Messrs. Bunyard's novelties, first introduced in 1896. It is a really excellent Apple for the table, and is in use from November to February. Fine specimens were seen at the Crystal Palace Fruit Show last week. (2) Borsdörfer is a Continental Apple, very highly esteemed in Germany, though hardly grown at all in this country. It is a free grower and very hardy, the fruit being yellow, and bright red next the sun, the skin also strewn with yellowish or brown dots. It was first grown in England in 1785. Apple Newton Wonder (page 287) was raised by Messrs. J. R. Pearson and Sons. It does not succeed in Kent, we believe, but is one of the best all-round Apples in other parts of the country. The Apple is now much appreciated, but we draw attention to it, believing that a good thing cannot be too well known. Pear President Barabé (page 286) is an excellent melting Pear of medium size. It is hardy and a good cropper. At Sawbridge-worth it is in favour.

## British Grown Fruit.

CRYSTAL PALACE, SEPT. 18TH, 19TH, AND 20TH.

It is said that the season's products are three weeks late this year owing to inclement weather. This, with the date of the show brought forward a fortnight, makes a difference to growers of five weeks as against a warm and favourable year. It is a wonder that so good an exhibition was possible following these sunless seasons, with their coldness, their storms, and rain.

Grapes were good on the whole: Apples and Pears had not the colour, though they may have been as heavy, as in a good year. A number of trade exhibitors, who on former years staged remarkably fine collections of fruit, or groups of trees, were not represented. The great storm which swept over Kent a day or two previous to the show may also have ruined the fruits of some intending exhibitors. Mr. Geo. Woodward, of Barnham Court, who generally stages some of the most superior samples on view at this show, was able to contribute a unique assortment of fruits, or, rather, parts of fruits—the remains of what had been handsome specimens previous to the devastating onslaught of hail which destroyed the whole of his fruit crops, and even riddled and tore to pieces his Strawberry plants, vegetables, and Chrysanthemums. The damaged fruits at the Palace were an object lesson in the risks and uncertainties of gardening, and it is the knowledge and probability of risks and losses which gives the greater satisfaction when labours are well rewarded and successfully crowned.

Messrs. Bunyard's display of fruit and pot trees deserved all the appreciation which the public accorded to it. Probably no finer effort has been made by this firm for some years. Messrs. Cannell and Sons had a new form of stand, or fruit-supporter, on their table. This was formed of a four-sided, erect central wooden rod, surmounted by a small wire basin for fruit. Fixed to the sides of this rod were horizontal brass wires, half an inch in thickness, with a circular basin for holding a plate at the end. These brass rods could be separated from the central support by simply lifting them out of the socket in which they are placed. Messrs. Peed and Sons used a neat little spring holder for their name cards, these being attached to the plates as a gentleman's tie-fastener might be, and the card was neatly held forward to the view.

A new feature of this exhibition were the collections of bottled fruits and jams. Never before has so large a display been seen. Practical demonstrations in the art of fruit bottling were given each day at 3 p.m. by Mr. Fowler to Fellows of the Society, but we were unable to attend to any of these. The Surrey Bee-keepers Society held an exhibition adjoining that of the Royal Horticultural Society.

In the way of novelties for another year, might it not be desirable to offer a prize for the best assorted collection of fruits of neglected native fruiting plants, or of plants with edible fruits, hardy in this country, and which are little known?

The Council of the Society, under the chairmanship of the President, Sir Trevor Lawrence, Bart., sat down to luncheon with the judges and others at 1.30 p.m. on the Thursday. In his remarks following the luncheon, Sir Trevor alluded to the bottled fruit, and remarked that, in his opinion, British bottlers had still something to learn if they are to compete with foreigners. He also briefly referred to the Horticultural Hall, and said that Baron Schröder taking the interest in it which he did, there was no need to fear that the scheme would not reach a satisfactory and successful issue. He proposed, after the loyal toasts, that of The Judges. This was ably and sensibly replied to by Mr. J. McIndoe, of Hutton Hall.

The Thursday, or first day of the exhibition, brought hosts of visitors, there being over sixty thousand people in the Palace and grounds during the evening. The arrangements in connection with the fruit exhibition were managed with the usual smoothness, the responsible persons being the Rev. W. Wilks, the Secretary; Mr. S. T. Wright and Mr. T. Humphreys, Superintendent and Assistant Superintendent of the Society's gardens; Mr. Reader, the Cashier, and Mr. Castleton, gardener to the Crystal Palace Company.

### Division I.—Gardeners and Amateurs.

*Collections of Indoor Fruit.*—The premier class for a collection of nine dishes, in six kinds, always makes a great show, and the exhibitors are particularly anxious to score in this class. On this occasion there were three competitors, but the quality of the produce, taken as a whole, appeared rather below par. Most of the Grapes were poorly coloured. The Peaches and Nectarines were, however, of exceptional character. Mr. J. H. Goodacre, gardener to the Earl of Harrington, Elvaston Castle, Derby, was placed first, staging good bunches of Muscat of Alexandria, fine in berry; Gros Maroc, clean, well-finished clusters. The Peaches Sea Eagle and Exquisite were grand in size and colour. A good dish of Victoria Nectarines, which possessed far more colour than is usual in this variety; a splendid dish of Figs, the variety being Brown Turkey; well coloured Washington Apples; a splendid dish of Marguerite Marillat Pears; Peaches Barrington and Gladstone, Clapp's Favourite Pear, and Dryden Nectarines being in excellent form; and a good Countess Melon completed the exhibit. Mr. J. Lock, gardener to Sir C. Swinfen Eady, K.C., Weybridge, Surrey, made a splendid second, and must have only just lost first place. The Grapes were grand, especially the Muscat of Alexandria, which were perfect in colour. Mr. J. Barson, gardener to the Earl of Sandwich, Hinchingsbrooke, Huntingdon, came third. The chief features of this exhibit were the Grapes Muscat of Alexandria and Gros Maroc, an enormous Countess Melon, and a good dish of Barrington Peaches.

The second collection of six dishes of ripe fruit, four kinds at least, Pines excluded, brought out four exhibits. Mr. W. Mitchell, gardener to J. W. Fleming, Esq., Chilworth Manor, Romsey, proved the victor. The varieties employed were Muscat of Alexandria, rather poor in colour, and Madresfield Court Grapes; a grand dish of Princess of Wales Peaches, Nectarines Pineapple and Pitmaston Orange, with Williams' Bon Chrétien Pears, forming a clean, well-finished exhibit. Mr. W. Harrison, gardener to Colonel Archer Houlton, Hallingbury Place, Bishops Stortford, was a capital second, having good dishes of Gros Maroc Grapes, Gladstone Peaches, and Clapp's Pear. Mr. W. Howe, gardener to Amy Lady Tate, Streatham Common, was third.

*Grapes.*—The classes for Grapes were well represented throughout, and although the colouring of the white varieties was not up to the mark, the blacks were good. Class 3 represented six distinct varieties of Grapes, three black and three white, and it is to be regretted there were only two entries. The first prize was awarded to Mr. W. Shingler, gardener to Lord Hastings, Melton Constable, and was in every way worthy of that exhibitor's reputation. The varieties were Gros Maroc, represented by good bunches of well coloured berries; Mrs. Pearson, good, shapely bunches, of fair colour, with moderate sized berries; Alwick Seedling, large in bunch, of excellent colour, but the berries would have been much better with a more severe thinning; Black Alicante, was large in bunch, but rather deficient in colour, the berries also showed signs of overcrowding. The Muscat of Alexandria were well coloured and large, though some of the berries were shrivelling; Gros Colman finished the exhibit. This variety was rather weak in colouring, otherwise good. The exhibit, taken as a whole, was undoubtedly a good one, and worthy of the show. Mr. J. H. Goodacre, gardener to the Earl of Harrington, Elvaston Castle, Derby, followed with a nice clean exhibit, but lacking in size when compared with the first prize exhibit. The best varieties were Muscat of Alexandria, rather small in berry, but well coloured; Barbarossa, enormous bunches of good colour, though rather small in berry; Gros Maroc, neat in bunch and berry; and Madresfield Court, which was small in bunch but otherwise good.

Black Hamburgh, three bunches, was represented by six entrants, and the general quality exhibited throughout was satisfactory, but there was nothing of a startling character in the exhibits. The first prize was awarded to Mr. W. Mitchell, gardener to J. W. Fleming, Esq., Chilworth Manor, Romsey, for three well coloured bunches of medium size, but decidedly small in berry. Mr. J. H. Goodacre was second with similar bunches, somewhat lacking in colour; while Mr. G. Lane, gardener to Miss Ridge, Highfield, Englefield Green, Surrey, was third, with slightly smaller bunches.

Mrs. Pince was represented by one exhibitor, Mr. W. Taylor, gardener to C. Bayer, Esq., Tewkesbury Lodge, Forest Hill, who staged quite moderate clusters.

The three bunches of Black Alicante brought four entries, all of good quality. The first prize was awarded to Mr. H. H. Brown, gardener to G. C. Raphael, Esq., Castle Hill, Englefield Green, for splendid bunches of well coloured berries. Mr. W. Shingler followed with three bunches of perhaps double the weight, of good colour, but very unshapely. Mr. W. Taylor followed with pretty clusters, which were rather underthinned.

Class 8 was for three bunches of Madresfield Court, and the variety was represented by five entries, but none of them could be described as of first-rate quality, there being a lack of finish. Mr. W. Mitchell was placed first with good bunches, but the berries, though large, were rather green at the base. Mr. J. H. Goodacre was second with small clusters of better colour; and Mr. W. Taylor brought up the rear in satisfactory style.

The class for "any other black Grape," three bunches, is always an interesting one, and brought out eight entries. Mr. W. Shingler was placed first with immense bunches of Gros Colman, of excellent finish and colour. Mr. George Lane followed with three good bunches of Appley Towers, which were of excellent colour and well finished. Mr. W. Mitchell came third with Gros Maroc; these were fine and well finished.

For three bunches of Muscat of Alexandria, eleven competitors faced the judges. Mr. W. Lane, gardener to Sir E. D. Lawrence, Bart., King's Ride, Ascot, was placed first with three grandly coloured bunches, some of the best seen this season, perfectly golden. Mr. J. Lock, gardener to Sir C. Swinfen Eady, K.C., Oatlands Lodge, Weybridge, followed with large, well coloured bunches, showing signs of shrivelling; and Mr. C. Sutton, gardener to Earl Stanhope, Chevening Park, Sevenoaks, made a good third.

All the other white Grapes were lumped into one class, which did not do them justice. There were six exhibitors, but the class did not produce anything striking. Mr. George Lane was first with three large bunches of Chasselas Napoleon. Mr. W. Taylor was placed second with the same variety, though they lacked the regularity of the first prizewinner's; and Mr. J. H. Goodacre came third with the same variety.

The collections of thirty dishes of hardy fruit, distinct, grown entirely in the open, not to include more than twelve varieties of Apples or eight of Pears, brought out three collections. Mr. W. Lewis, gardener to R. B. H. Marsham, Esq., East Sutton Park, Maidstone, proved the victor. The varieties were The Queen,

Apple, Allington Pippin.

(See page 231.)

Lane's Prince Albert, Ecklinville, Lord Suffield, Warner's King, Peasgood's Nonsuch, Alfriston, New Hawthornden, Annie Elizabeth, Emperor Alexander, Lady Sudeley, and Cox's Orange Pippin, in Apples, all of which were of moderate quality. The Pears were about the same in quality, and were represented by Beurré Baltet père, Williams' Bon Chrétien, Souvenir du Congrès, Clapp's Favourite, Triomphe de Vienne, Marguerite Marillat, Pitmaston Duchess, and Fondante de Thirriot. The remaining dishes consisted of Morello Cherries, Plums Pond's Seedling (good), Monarch, President, and Golden Drop; a capital dish of Red Dutch Currants, Walburton Peaches, Pineapple Nectarines, and Brown Turkey Figs completed the display. Mr. E. Coleman, gardener to T. L. Boyd, Esq., North Frith, Tonbridge, made a capital bid for second place. The Pears were the chief feature, some of the most notable being Doyenné Boussoch, Marguerite Marillat, Pitmaston Duchess, Clapp's Favourite, and Beurré d'Amanlis. The best Apples were Ecklinville, Stirling Castle, Peasgood's Nonsuch, and Lord Derby. Pond's Seedling Plums and Peaches Bellegarde and Stirling Castle were also good. Mr. Berryman, gardener to T. Barnett, Esq., Knighton Grange, Chichester, made a good show for third place. The features of this exhibit were Uvedale St. Germain Pears, which were extra large, Peasgood's Nonsuch Apples, and the Plums Magnum Bonum, Grand Duke, and Kirke's Blue Gage.

The collection of orchard house fruit, consisting of twelve dishes, grown partly or entirely under glass, Grapes excluded, brought out but a poor entry, there being only two contestants. Mr. J. H. Goodacre, however, staged a fine exhibit, and won the first prize, hands down. The exhibit was remarkable for size and colour in every dish; this was clearly in evidence. The kinds employed were: Apples, Washington and Ribston Pippin; Pears, Souvenir du Congrès, Marguerite Marillat, and Souvenir du Conice. The Peaches were unusually fine and of excellent colour, good dishes of Princess of Wales, Exquisite, Royal George, and Barrington being in evidence. A good dish of Victoria Nectarine and a dish of Strawberries, the name of which was unreadable, completed the show. Mr. R. Edwards, gardener to C. A. Morris-Field, Esq., Beechy Lees, Sevenoaks, an old exhibitor in this class, was second, his best dishes being King of Tomkins County and Washington Apples, Pears Triomphe de Vienne and Clapp's Favourite. In Plums he had Coe's Golden Drop and Monarch, each conspicuous.

#### Division II.—Nurserymen's Classes.

*Hardy Fruit.*—The premier class in this division is one that always creates great interest. The schedule reads: "For fruit grown entirely in the open air, a space of 48ft run of 6ft tabling." Mr. H. Berwick, Sidmouth, Devon, came out at the top of the tree with a capital display for the season. The Apples and Pears were considerably below par, though they were clean and fresh. The Plums were, however, good. The best dishes of Apples were Bismarck, Potts' Seedling, Tyler's Kernel, Gloria Mundi, Sandringham, Wealthy, Warner's King, Peasgood's Nonsuch, Ecklinville Seedling, and Emperor Alexander. The most prominent Pears were King Edward, Gratioli de Jersey, Grosse Calebasse, Williams' Bon Chrétien (extra good), and Beurré Clairgeau; while the best Plums were Kirke's, Pond's Seedling, Victorias, and Orleans. Sea Eagle and Royal George Peaches were also staged. The exhibit was as good as could be expected as far as quality was concerned, and the arrangement was quite satisfactory. Messrs. H. Cannell and Sons, Swanley, were second

Apple, Borsdorfer.

(See page 284.)

with a well displayed exhibit, the foliage employed being most effective, and the flatness of the exhibit was relieved by pyramids of well coloured Apples arranged with appropriate foliage. The most noteworthy examples in Apples were Stirling Castle, Cellini, Lord Suffield, Peasgood's Nonsuch, Lord Derby, Bismarek, and Duchess of Oldenburg. Some good Plums were staged, with Nuts, "Crabs," Damsons, and examples of the Strawberry-Raspberry.

The class for 32ft run of 6ft tabling encouraged two exhibitors to take the field. Here Messrs. J. Cheal and Sons, Crawley, came out first with a creditable display of Apples, Pears, Plums, Peaches, and Nectarines, the whole exhibit being well arranged. The best Apples were Castle Major, Walthamstow Beauty, Warner's King, Jubilee, Gold Medal, and Bismarek; while in Pears Glou Moreau, Pitmaston Duchess, Flemish Beauty, Catillac, and Doyenné du Comice were most conspicuous. Of the Plums Pond's Seedling and White Magnum Bonum were of grand size. Peaches and Nectarines were also of good size. Messrs. J. Peed and Son, West Norwood, came in a good second, evidently relying on their Apples and Pears for their position. This exhibit was chiefly displayed in baskets and dishes, while a centrepiece was formed of a pyramid of Apples and Pears, with Palms at the corners. Some of the best dishes were Peasgood's Nonsuch, Lane's Prince Albert, Hawthornden, Gloria Mundi, Forge, Ribston Pippin, and Byford Wonder. The Pears were large and clean, a few of the most prominent being Pitmaston Duchess, Durondeau, Clapp's Favourite, Tardive de Solesnes, and General Todleben constituting the best feature of the exhibit. Plums were also represented by several varieties.

The class for 16ft run of tabling by 6ft wide seemed to suit the exhibitors this season, for four entered in this class. However, Mr. Geo. Mount, The Nurseries, Canterbury, so noted for his Roses, proved that the Kentish firm can also turn out good fruit on occasions like this, by winning the first prize. The exhibit was tastefully arranged, and the produce undoubtedly good, the colour in the Apples being noteworthy. Mention should be made of excellent baskets of Apples Peasgood's Nonsuch, Bismarek, Cox's Pomona, Royal Jubilee, Lord Suffield, Lady Sudeley, Worcester Pearmain, and Mère de Ménage. The finest baskets of Pears were Beurré Hardy, Williams' Bon Chrétien, Conference, Souvenir du Congrès, Margaret Marillat, Clapp's Favourite, Beurré Diel, and Beurré d'Amanlis; while good baskets of Pond's Seedling, White Magnum Bonum, Grand Duke, and Cox's Emperor were the best Plums, and a few dishes of "Crabs" completed the exhibit. Messrs. S. Spooner and Sons, Hounslow, made a good second, though they lacked the colour so prominent in the previous exhibit. Good examples of Royal Jubilee, Frogmore Prolific, Duchess of Gloucester, Sandringham, Gascoyne's Scarlet, Williams' Favourite, and Worcester Pearmain were good in Apples. A few dishes of Pears and some excellent Monarch Plums completed the chief points of this exhibit. Messrs. J. Laing and Sons, Forest Hill, made a tasteful exhibit for third place. The pieces of Cratægus Lelandi and Asparagus gave a pretty effect. The most noteworthy dishes and baskets in Apples were Pott's Seedling, Bismarek, Bellamy's Fillbasket, Royal Jubilee, Lord Suffield, Tyler's Kernel, Peasgood's Nonsuch, and Lord Derby; while good examples of Grosse Calebasse, Pitmaston Duchess, Marie Louise, Louise Bonne of Jersey, Clapp's Favourite, and Souvenir du Congrès were the most prominent Pears, and a few dishes of Plums and "Crabs" completed an effective display.

#### Division III.—Market Growers.

This division of the schedule started with class 19, for four varieties of cooking Apples in baskets or boxes of about 42lb net, the prizes being 30s. and 20s. respectively for first and second. With admirable samples of The Queen, Lord Suffield, and Bismarek, all of which were large, well-modelled samples, of good colour, without a blemish, the first award fell to Mr. H. T. Masson, of the Rectory Farm, Hampton Hill. Mr. Poupart, of Marsh Farm, Twickenham, was second with large green fruits of Warner's King, Lane's Prince Albert, and Peasgood's Nonsuch, but otherwise these were useful samples. There were only three entries.

For four varieties of the dessert Apples, weighing about 20lb, three bright lots from Mr. Geo. Chambers, of Mereworth, Maidstone, brought him the leading award. He staged Quarrenden, Cox's Orange Pippin, and King of the Pippins. Second out of four came Mr. Poupart with King Pippin, Worcester Pearmain, and Wealthy. Only two entrants showed for the two varieties of cooking Apples, the first place going to Mr. G. Chambers, of Maidstone. In the succeeding class for two dessert varieties, Mr. Mason, with King of the Pippins and Cox's Orange, beat his only opponent, who did not receive a prize. There was no entry at all in class 23, but four competed in the next, for two packages in two kinds of Pears, the premier award here falling to Mr. A. Wyatt, of Hatton, Middlesex, with a large flat boxful of Durondeau and Souvenir du Congrès. The samples were large and good, much better displayed, too, than those of Mr. Geo. Chambers, who came second. Three lots of Pears, of from twenty-four to forty-eight fruits, according to size, of any one choice dessert

**Pear, President Barabé**

(See page 284.)

Pear, were shown in class 25, and Mr. Poupart led, having Pitmaston Duchess, even and clean. These were packed in a flat, oblong box, with paper around each. Second came Mr. Wyatt, with a similar box, containing Souvenir du Congrès.

In class 26, for a collection of twelve varieties of Apples and six of Pears, distinct, eighteen fruits of each, to be laid flat on the table without dishes or baskets, only Vine or similar leaves allowed for decoration, and the space occupied must not exceed 16ft by 3ft, four creditable lots were displayed, the first and second being very nearly equal, as it seemed. Mr. Poupart, who led, had the larger fruits, and they were well spaced out, giving them an imposing effect. The succeeding award fell to Messrs. W. J. Lobjoit and Son, Heston Farm, Hounslow, with somewhat brighter samples, but less in size, as we remark. Poupart's Pears, in the varieties Clapp's Favourite, Marguerite Marillat, and Durondeau were very fine samples, as were his rosy-cheeked Worcester Pearmain Apples and very handsome Peasgood's. The Mère de Ménage were very irregular.

For a basket of about 28lb of cooking Plums, there were superb fruits of that grand sort Monarch on view from Mr. Poupart, giving him an easy lead. Lighter coloured, but also very good fruits of the same variety came from Messrs. Lobjoit, who were second, out of four. They were quite alone, however, in the next class, for a package of one dessert variety, staging a poor lot of Coe's Golden Drop.

Peaches were not numerous, though the two dozen fruits of Sea Eagle, packed in a box for market, with paper and cotton wool round each, and embedded in wood wool, from Mr. J. Gove, Albion Nursery, Polegate, Sussex, were really of very great merit, and a credit to him. After his, out of four, came Mr. W. J. Noy (gardener, Mr. W. Buckingham, The Homestead, Brentford, with Exquisite, highly coloured and large.

#### Division IV.—Open Air Fruits.

*Open to gardeners and amateurs only.*—The two classes leading off here, namely, 30 and 31, were unsupported. J. R. Brougham, Esq. (Mr. W. Jones), Wallington Bridge, Carshalton, and R. Marsham, Esq. (gardener, Mr. W. Lewis), East Sutton Park, near Maidstone, Kent, were equal first for twelve distinct dishes of Apples, eight of cooking and four of dessert. The finest samples here were Bismarek and Emperor, both for cooking, in Mr. Brougham's, with the dessert sorts Okera and Worcester Pearmain, in Mr. Marsham's. Okera is an oblong, brick-red coloured Apple, of distinction. In class 33, for six dishes of cooking Apples, only one exhibitor—Rev. O. L. Powell, Woburn Park, Weybridge—was forward. The samples were large and clean, but very green. Peasgood's and The Queen were well shown.

*Coming to Pears*, we found no entry for the half-dozen dessert sorts, and only one exhibit was contributed, this being certainly very creditable, from Sir M. Samuel's gardener (Mr. W. H. Bacon) of Mote Park, Maidstone. Evidently these had been well seen to, or had been out of range of the recent storm in that district. Beurré Mortillet was absolutely superb, and there were beautiful dishes of Directeur Hardy, Conference, Fondante de Thirriott, Doyenné Boussoch, Triomphe de Vienne, and Zephirin Gregoire (?). These were admirably staged, and it is unfortunate that there should have been nothing against such a collection,

that the honour of being foremost might have been experienced. Rev. O. L. Powell contributed the solitary collection of twelve dishes of dessert Pears, and had plump fruits of Doyenné Boussoch, Beurré de Mortillet, and Glou Morceau.

Again there was but one entry in class 37, for the nine dishes, Mr. W. Jones, of Wallington Bridge, being the exhibitor. His samples were very green, but unblemished in any respect. For the six, two were forward. C. Morris-Field, Esq. (gardener, Mr. R. Edwards), Beechy Lees, Sevenoaks, beat Alfred Benson, Esq. (gardener, Mr. W. Maney), Upper Gatton Park, Merstham, though the difference must really have been exceedingly slight. The former contributed lovely fruits of the useful Gansel's Bergamot and Triomphe de Vienne, and had a good dish of Clapp's Favourite.

Peaches furnished a wonderfully bright display of colour, and charming fruits were shown by Mr. C. Earl, gardener at Summerhill, Tonbridge, and Mr. C. Page, of Dropmore, Maidenhead, who led in classes 39 and 40 respectively. The seconds here were Mr. J. H. Goodacre and Mr. Joseph Sparks, of Grove Park, Roehampton Lane, W. The first of these classes was for six dishes, and the second was for three. The finer varieties (and all were from the open) were Sea Eagle, Exquisite, Thames Bank, Dymond, Royal George, Gladstone, Dr. Hogg, Princess, Bellegarde, Gros Mignonne, and Violette Hâtive. A dish of Walburton Admirable was shown, but these were poorly coloured, though large. In class 41, for a dish of one variety, a keen competition was shown, there being eight dishes. Mr. W. Humphries, gardener to the Earl of Chesterfield, of Home Lacey, Hereford, was a very good leader, having six fine fruits of Barrington, of large size and bright colour. Following him came Mr. J. Lock, gardener to Sir Swinfin Eady, K.C., Otlands Bridge, Weybridge, with Royal George, and Mr. W. Mitchell, gardener to J. W. Fleming, Esq., of Chilwell Manor, Romsey, with Sea Eagle, both equal seconds.

Nectarines did not make such a large display, but their colours were quite distinct and deep. For the three dishes, fruits to be grown out of doors, Mr. Earl, of Weybridge, beat Mr. T. Turton, of Sherborne Castle, Dorset—a good second. The former staged Darwin, Spencer, and Prince of Wales; the latter Stanwick Elruge, Rivers' Orange, and Spencer. Only three entered. For the one dish there were five contestants, but Mr. J. Lock, of Weybridge, led, with six of the handsomest Drydens at the show. Second came Mr. Goodacre, with a dish of unnamed fruits.

Plums were beautiful, and certainly of very high quality after such a season. Three lots of Plums were set up in class 44, comprising each three of dessert and six of cooking. The leading place was ably won by Mr. G. Grigg, gardener to the Earl of Ashburnham, from Battle. His contribution is well worth naming, and the varieties were White Magnum Bonum, Black Dymond, Transparent Gage, Rivers' Late Gage, Jefferson, Pond's Seedling, Belle de Louvaine, Cox's Emperor, and Grand Duke. These were carefully displayed, the fruits themselves being large, plump, deeply coloured, and covered with a fine bloom. With noticeably smaller fruits, but otherwise of equal merit, Mr. W. Pope, gardener to the Earl of Carnarvon, Highclere Castle, Newbury, formed a good second. He staged Bryanston Gage,

Kirke's, and Magnum Bonum. A poor dish of Victorias was included.

Mr. C. H. Colegate, of Catsfield Place, near Battle, led for the six (four cooking and two dessert), his best being Pond's Seedling. Second came Mr. T. Turton, out of four. Mr. Goodacre was second for three dishes of Gages, with translucent little sugary globes of Transparent Gage, Guthrie's, and the Bryanston's Late. In this class Mr. Colegate was disqualified from having Kirke's Plum, which is not a "Gage." Seven staged dishes of one variety, the leading place being accorded to Mr. Turton with dark amber and red coloured Jefferson's. Second place was occupied by Mr. James Vert, of Audley End, Saffron Walden, also with Jefferson. A perfect dish of Coe's Golden Drop received no award. For one dish of a cooking variety we find Mr. Grigg a good first with White Magnum Bonum; he was closely followed by Mr. Turton, with large specimens of Pond's Seedling, out of twelve contestants.

#### Division V.—District County Prizes.

This section of the schedule was devoted to special district county classes, and was open to gardeners and amateurs only. Class 49 led off, and this was open to Kent growers. For the six dishes of Apples the leading place was captured by Mr. E. Coleman, North Frith, Tonbridge, with large fruits of the usual exhibition favourite varieties; and second, Mr. R. Edwards, Beechy Lees, Sevenoaks, with a slightly less even lot, but good. For Pears in the same class, the first was again accorded to Mr. Coleman, with Mr. R. Edwards second.

Class 50, open only to growers in Surrey, Sussex, Hants, Dorset, Somerset, Devon, and Cornwall. Apples: Mr. C. H. Colegate, Catsfield Place, near Battle, formed an excellent first, with fine samples of Ecklinville, Warner's, Ribston, Peasgood's, and Bramley's Seedling. Second place was filled by Mr. Turton with brightly coloured dishes of Worcester Pearmain and good Peasgood's. There were four entries. In the Pear classes Turton was leader, and Coleman a favourable second. Their best dishes were Beurré Mortillet, Clapp's Favourite, Triomphe de Vienne, and Beurré Superfin. The colour was good in each of these.

The succeeding class was for growers in Wilts, Gloucester, Oxford, Bucks, Berks, Beds, Herts, and Middlesex. Three lots of Apples represented the western men, and here we found Mr. Strugnell, the able gardener to Colonel Vivian, at Rood Ashton, Trowbridge, in the van, with Mr. C. Page, of Dropmore, as second. Mr. Strugnell had moderately sized fruits, but unblemished and rather bright. His best were Peasgood's, Annie Elizabeth, and Mabbott's Pearmain. The Dutch Codlin, too, was exemplary. For Pears the first award was accorded to Mr. W. H. Bannister, of Cote House, Westbury-on-Trym, and a charming display they made. Few fine samples were on the boards. Beurré Hardy and Doyenné Boussoch were typical. Second came Mr. C. Page.

In class 52, open only to growers in Essex, Suffolk, Norfolk, Cambridge, Hunts, and Rutland, there was only one exhibit of Pears (no Apples), and that came from Mr. W. Harrison, gardener to Colonel Archer Houbton, Hallingbury Place, Bishops Stortford.

The next class was open only to growers in Lincoln, Northampton, Warwick, Leicester, Notts, Derby, Staffs, Shropshire, and Cheshire. For Pears the first prize fell to Mr. W. H. Divers, gardener to the Duke of Rutland, Grantham, with rather moderate sized fruits and very green. He also led for Apples. Second for Pears came Henry Knott, Esq., J.P., of Stamford, who also was so placed for the Apples, showing a pretty dish of Queen Caroline variety among others.

Class 54, open only to growers in Worcester, Hereford, Monmouth, Glamorgan, Carmarthen, and Pembroke. Mr. J. Rick, gardener to G. H. Hadfield, Esq., Moraston House, near Ross, led for Apples, and included here a splendid six of Lord Derby, Bramley's Seedling. Following him came Mr. J. E. Jones, of Kynaston, Ross, with fine fruits. Mr. Rick, was foremost for Pears, having beautiful fruit of good size, colour, and general finish for the season. Second came Mr. W. Humphries, gardener to the Earl of Chesterfield, with large but greener samples. There were two lots of Apples and three of Pears.

The Welsh growers did not contribute anything that was at all noteworthy here. For six dishes of Apples the leading award went to Mr. H. Forder, of Ruthin Castle, N. Wales, with undersized, irregular, and green fruits. Mr. Fox, of Highmead, Llanybyther, S. Wales, came a close second, out of three. Mr. Forder led also for Pears, but these, too, showed the effects of a bad season. Mr. Fox had ruddy samples.

Number 56 of the schedule was open to growers in the six northern counties of England, and in the Isle of Man. Three collections were forward, with Mr. Geo. Picker, gardener to J. R. Pease, Esq., Hesslewood, Hull, at the head. No second. Mr. McIndoe, gardener to Sir Joseph Pease, Bart., of Hutton Hall, beat Mr. Picker for Pears.

Scotland was represented only by one entry of Apples and another of Pears, both from Mr. Day, gardener to the Earl of Galloway, at Garliestown.

From Ireland there came a bright six dishes of Apples, in-

Apple, Newton Wonder.

(See page 284.)

cluding a choice set of The Queen, and also of Colonel Vaughan, shown by Mr. J. G. Weston, gardener to Viscount Duncannon, Bessborough, Piltown. The Channel Islands did not contribute this year.

#### Division VI.—Single Dishes.

Single dishes of fruit grown in the open air. Open to gardeners and amateurs only. The prizes in each case are 7s. for the first, and 5s. for the second.

#### CHOICE DESSERT APPLES.

*Class 60.—Adam's Pearmain.*—Of this three dishes were shown, and the first award fell to F. W. Thomas, Esq., of Wainock, Polegate, Sussex: the second to Jeremiah Coleman, Esq. (gardener, Mr. W. P. Bound), Gatton Park, Reigate, the former with excellent samples.

*Allington Pippin* brought only two dishes. Mr. W. Harrison, gardener to Col. Houlton, at Hallingbury, beat Mr. John McKenzie, of Linton Park, Maidstone, both with rather undersized and green samples.

*American Mother* had three dishes to its credit, the best lot being from Mr. McKenzie, of Maidstone, and the second from Mr. Turton.

*Benoni.*—Only two entries; the premier from Mr. F. W. Thomas, of Wainock, and the second from Mr. McKenzie.

*Blenheim Orange* and *Cardinal* had none to their credit, but

*Claygate Pearmain* had four entrants to support it, though they were poor and very green. Mr. D. G. Melvor, of Ossett Gray, Grays, Essex, first, and Mr. A. J. Carter, of Billingshurst, Sussex, second.

*Cox's Orange Pippin.*—Alas! for Cox's, that this famous Apple should only be shown in four lots. Mr. Bound, of Gatton Park, led, followed for second by Mr. T. W. Herbert, of Nutfield Court, Redhill, who must have been very close indeed.

*Devonshire Quarrenden.*—This fine showy Apple was six times shown, the best coming from Mr. Bound, and the second from Mr. G. Crabb, Park House Gardens, Addlestone. All the samples were creditable and well coloured.

*Duchess' Favourite* had but three dishes representing it. Mr. Crabb, with beauties, was a good first, and Mr. Melvor second.

*Egremont Russet* is generally seen in force at the Crystal Palace, but two dozen fruits were all here shown on this occasion. Mr. J. McKenzie beat Mr. C. Earl, the first with very creditable Apples.

*Fearn's Pippin* was not at all seen, and

*Gascoyne's Scarlet*, with three dishes of fruit, made a poor show. Mr. Earl had first with bright samples, and second, Mr. T. Clinch, of Sittingbourne.

The beautiful *Golden Reinette* was minus a single entry, nor was the old *Irish Peach* on view.

*James Grieve.*—Two here entered, and though somewhat close, yet Mr. F. W. Thomas, of Polegate, had the advantage, and beat Mr. W. Harrison.

*King of the Pippins* is another popular dessert variety, but only five came forward now. Mr. J. Lock, of Weybridge, was a moderate first, and Mr. Earl second.

*King of Tomkin's County* was four times on view, the best coming from Mr. Alex. Smith, the Convent Gardens, Roehampton Lane, and second, Mr. G. Grigg.

*Lady Sudeley.*—Wonderfully rich and showy fruits were forward, and those from Mr. W. Mitchell, of Chilwell Manor, Romsay, could not have staged finer samples, even in a sunny year; following him came Mr. Melvor.

*Lord Burghley.*—There were three lots here, each very poor indeed. Mr. A. J. Carter, of Billingshurst,

*Mannington Pearmain.* with four dishes, was well content. Mr. E. Colman had better samples than Mr. Chas. Ross, of Welford Park.

*Margil.*—Poor Margil! A winsome tot, with only the first and second prize lots representing it. Mr. McKenzie was first, and Mr. C. Ross second.

*Red Astrachan.* a good Apple, did not appear here; and what's the reason?

*Ribston Pippin* proved to be braver than most of its associates, seven lots having faced the judges. Mr. Grigg, with large, green samples, was in the lead, the next to him being Mr. C. Page. One lot, from under glass, was disqualified, of course.

*Worcester Pearmain* brought ten lots, and rosy they were—or, rather, crimson. Mr. W. H. Bannister admirably led, with Mr. J. Rick second, both showing very fine fruits.

*Any other variety, not named above,* brought forward seven entries. With *Golden Russet*, Mr. John McKenzie was placed foremost; Mr. Alex. Smith, of Roehampton, second, with Beaumont's Winter Reinette; and Mr. T. H. Slade, gardener to Lord Poltimore, of Poltimore Park, Exeter, third with *Wealthy*, which surprises us that there should not have been a class for this good variety.

#### Choice Cooking Apples.

*Class 86.—Beauty of Kent,* a handsome fruit; had none on this occasion by which to refresh the memory of it.

*Bismarck.*—Four entrants staged, but Mr. Alex. Smith won with very good fruits, and second, Mr. John McKenzie.

*Blenheim Orange* (large fruits).—Mr. E. Coleman, of Tonbridge, led out of three with green samples, Mr. J. E. Jones being second.

*Bramley's Seedling* had but two contributors of it, the awards falling to: First, Mr. A. Bassile, of Woburn Park, Weybridge, and second Mr. Wm. Lewis, East Sutton Park, near Maidstone.

*Cox's Pomona*, with but two, made no display. Mr. McKenzie led, against Mr. T. W. Herbert, of Redhill.

*Ecklinville* was well shown seven times, the best set coming from Mr. F. W. Thomas, of Polegate, with clear, smooth, large fruits; second came Mr. Alex. Smith.

*Emperor Alexander.*—Mr. J. McKenzie had the only dish, and these were really good.

*Frogmore Prolific.*—Of two, Mr. D. McAinster, Leeds Castle, Maidstone, was first, with fairly coloured, good Apples; Mr. McKenzie second.

*Gascoyne's Scarlet* (large fruits).—Three displays, and one lot from under glass was ignored from having been grown under glass, bright though it was. Mr. D. G. Melvor led, and Mr. Turton followed.

*Golden Noble* was anything but golden; indeed, as green as the newest grass, and only one entry was staged, that from Mr. McKenzie.

*Grenadier* had three dishes in its support, though only moderate in quality. Mr. D. McAinster beat Mr. McKenzie.

*Hawthornden, New.*—For this, Mr. E. Coleman won against Mr. T. W. Herbert, his only opponent.

*Lane's Prince Albert.*—Eight samples were seen. The first set, from Mr. A. Smith, were good, clean fruits, and well before those from Mr. C. Ross.

*Lord Derby* was twice shown, and very coarse and green. Mr. Alex. Smith beat Mr. Melvor.

*Lord Grosvenor.*—Six dishes of this were on view. Mr. A. J. Carter was first, and Mr. McKenzie second.

*Lord Suffield.*—Only three of these seen, and the monotonous repetition of a prizewinner's name—Mr. A. Smith—appeared on the first card.

*Mère de Ménage.*—Mr. McKenzie was here alone with fair samples.

*Newton Wonder.*—For eight fruits in class 104, Messrs. J. R. Pearson and Sons, Lowdham, presented the money prizes, as they also did in the succeeding class for the same variety. Class 104 was opened only to exhibitors living in Cardigan, Radnor, Shropshire, Stafford, Warwick, Northampton, Bedford, Cambridge, Essex, or counties further north. Mr. W. H. Divers, of Belvoir Castle, Grantham, was the only exhibitor from the north.

*Newton Wonder*, open only to exhibitors being south of the fore-mentioned counties.—Seven contested, and Mr. F. W. Thomas of Polegate, with good fruits, was accorded the lead. In the second place came Mr. W. Lintott of Marden Park, Surrey, also with good samples, but smaller.

*Peasgood's Nonsuch* had but three dishes in its favour, the premier lot from Mr. J. McKenzie being really models of high culture. Mr. W. Lewis of East Sutton Park followed a fair second.

*Pott's Seedling.*—Only two lots of these were on view, Mr. McAinsh leading with very creditable fruits.

*Royal Jubilee.*—Mr. Chas. Ross was foremost for six, he staging showy and large Apples. Out of seven, Mr. C. Sutton, Clevening Park, Sevenoaks, was second.

*Sandringham.*—Three lots were here, the best being from Mr. Ross.

*Stirling Castle* had six dishes, which is far below what this fine Apple usually brings forward. Mr. W. P. Bound was leader, and Mr. Ross followed.

*The Queen.*—Again Mr. Bound was in the van with a dish of the most showy samples in the show. Mr. A. Smith was a fair second, but his fruits were far behind in point of colour.

*Warner's King.*—Five dishes of this large sized variety were before the visitors, the judges awarding first to Mr. J. McKenzie with huge specimens, though very green; second, Mr. A. Smith, also with good samples.

*Any other variety not named above.*—Again the redoubtable Mr. Alex. Smith was leader with handsome and really fine fruits of Tyler's Kernel. Mr. McKenzie, with Queen Caroline, made an excellent second, his fruits being clear, smooth, of good size and colour.

#### Single Dishes—Pears.

In this division the Pears made even a poorer show than did the Apples. Taking the dessert Pears foremost, for *Beurré d'Amanlis* there were six, which, of course, was good. Mr. A. Bassile beat Mr. W. Lintott. The best dish of *Beurré Diel* was from Mr. A. J. Carter. *Beurré Dumont* was only once shown, and the second prize was awarded, Mr. E. Coleman being the recipient. Fair specimens of *Beurré Fouqueray* came from Mr. E. Coleman, and out of six entrants for *Beurré Hardy*, Mr. J. Rick led off, Mr. Bannister following.

Four lots of *Beurré Superfine* came up, Mr. Turton here leading, and Mr. Bannister being second. *Clapp's Favourite* was better shown than almost any other, there being six dishes of it. First was Mr. Lintall and second Mr. Grigg. The first lot were lovely coloured and very large as well. For *Comte de Lamy* Mr. T. W. Herbert staged nice little samples. Three sets of *Conference*—a fine Pear—were on view. Mr. J. W. Barks, Castle Hill, Bletchingley, out of three, was first.

*Doyenné du Comice*, which, according to Mr. Bunyard, is "The Best Pear," had but one dish as representing it, and this came from Mr. Barks. *Doyenné Boussoch* brought five sets, the finer examples being staged by Mr. J. Rick, and the next best by Mr. Bassile. The russet-brown and characteristically shaped

Durendeau, a good pot Pear, had three dishes, Mr. Turton heading fairly, and Mr. Bannister following for second. Emile d'Heyst, with five, was seen to advantage, the foremost samples being from Mr. T. H. Slade, of Poltimore Gardens, Exeter, and Mr. E. Colman second. For Fondante d'Automne there were three contestants, the premier card being accorded to Mr. W. Hawe, of Streatham, with nice smooth fruits, second Mr. Coleman.

Dr. Jules Guyot had no representative. Ten dishes were forward at the call of Louise Bonne of Jersey, the first place being filled by Mr. F. W. Thomas with fair samples; second came Mr. McAinsh. Marguerite Marillat is a handsome variety, and three lots were entered, Mr. Slade beating Mr. Thomas, having very good samples of this early Pear. Marie Louise brought eight competitors, but Mr. Rick again proved the winner, Mr. Turton following. The fruits were very green. For Pitmaston Duchess, Mr. T. Horsey, of Charlton House, Sudwell, Salisbury, led, with large but green samples. Mr. J. W. Barks was second, out of eight. The pretty and quaint little Seckle had four purple sets in its favour, Mr. Chas. Ross coming to the front, and was followed by Mr. Coleman.

Souvenir du Congrès with four found Mr. Rick leading, Mr. Bassile being second. The fruits were large but not very shapely, and they were green. Thompson's had little size or colour. Out of two Mr. C. Page was first. The delicious Triomphe de Vienne had but three dishes, Mr. Turton, with really good fruits (large and well coloured), beating Mr. F. W. Thomas. Williams' Bon Chrétien brought three entrants, Messrs. J. Rick and T. W. H. having the awards, the former with well coloured Pears. The last class here, that for "any other variety," was supported by only three competitors, the leading place falling to Mr. E. Coleman with Aspasia Ancourt; second, Mr. P. W. Bound, with splendid Gansel's Bergamotte; and third, Mr. Bassile, with Summer Fraunce.

#### Division VII.—Miscellaneous.

Class 139.—Home preserved or home bottled British grown fruits. Open. This exhibit must not occupy a space greater than 8ft by 6ft, and must not be built up more than 2ft high in the centre. Jams in clear glass jars or bottles; bottled fruits in clear glass bottles; small quantities of fruits, preserved, dried, or evaporated, in any other way may be included, but all alike must be British grown and British prepared. First prize, Gold Medal; other prizes at the discretion of the Council. Messrs. Austin and Co., Kingston-on-Thames, who are the possessors of a patent and secret bottling process, were placed first, their exhibit displaying well preserved and finely coloured fruit samples. The second award we were unable to find; and third the Swanley Horticultural College. There were five displays.

Class 140 was for home preserved or home bottled British fruits. Wholesale firms excluded. This exhibit had to include both jams and bottled fruits—from twelve to eighteen 1lb or 2lb clear glass pots or bottles of jam, including at least four different kinds, and from twelve to eighteen bottles of fruit, including at least four different kinds. Small quantities from ½lb to 1lb of any British grown fruit preserved at home in any other way may also be added. Any of the pots or bottles in each exhibit will be opened by the judges at their own selection. Everything exhibited must have been preserved by the exhibitor. First prize, a Silver Cup presented by the Countess of Warwick; second, £3. The Horticultural College, Swanley, were first; Mrs. A. Bassnet, Shirley, Croydon, second; and third, the Lady Warwick Hostel, Reading.

Class 141 was for exhibits of a dozen bottles of bottled fruits (including four different kinds at least), bottled and shown by exhibitors who do not sell their produce or in any way work for the trade (wholesale or retail), but only and entirely for their own household consumption. First prize, £3; second, £2. Allanson Bailey, Esq. (gardener, Mr. W. Elliott), Mount Pleasant, Farningham, was first; Mr. J. Bushnell, Sandling, Maidstone, second; and third, Mrs. Banks, Hasland Hall, Chesterfield.

For an entry in class 142 (miscellaneous), Mrs. W. H. Plowman, Heath Cottage, Beddington Corner, Mitcham, received an award.

#### Non-competitive Exhibits.

Undoubtedly the largest and finest collection of fruit on view from one firm was that of Messrs. Geo. Bunyard and Co., Maidstone. The tabling occupied the whole length of the show area. Pot trees were staged at the back, these including nicely trained specimens of Apples, Pears, Plums, and the Cherry Guigne de Winckler, an October fruiting variety, bearing heavy clusters. Cox's Emperor Plum and Peasgood's Apple showed up well. Among the dishes of fruit on the table were Cox's Pomona, Ben's Red, James Grieve, Bismarck, Lady Henniker, Royal Jubilee, Allington, Ribston Pippin, Queen Caroline, Lady Sudeley, Duchess of Gloucester, Preston Hall, Washington, Colonel Vaughan, Evagil, Lord Derby, Lord Grosvenor, The Queen, and Beauty of Kent Apples; Doyenné Boussoch, Uvedale's St. Germain, Fondante d'Automne, Dr. Joubert, and other Pears; Melon Little Heath, Peaches, Nuts, Damsons, Plums, and Crabs. The group was the object of the greatest interest during the run of the show.

A large number of trade exhibits, apart from fruit, were contributed. Messrs. Cutbush and Son had a collection of cut Dahlia blooms, and so also had Messrs. Cheal and Sons. Messrs. D. S. Thomson and Son, of Wimbledon, set up a group of the new double flowering Gypsophila paniculata. Mr. Will Taylor, of Hampton, had Roses, and a group of these also came from Paul and Son. Messrs. Cannell and Sons had a conical mass of their gorgeous Cannas, while hardy flowers came from Messrs. Pritchard, T. S. Ware, Limited, and Geo. Bunyard and Co. Barr and Sons had Montbretias, Roses, Amaryllis Belladonna, Phloxes, Delphiniums, Asters, and Physalis Alkekengi, &c. Messrs. J. Peed and Sons had double tuberous Begonias and hardy flowers. From Messrs. B. S. Davis, of Yeovil, there also came superb tuberous Begonias. Amongst the doubles there were the following, which are very fine: Mrs. Shortland, yellow; W. Sparshott, rich crimson; Ernest J. Davis, Marchioness of Bath, white; Captain Henderson, scarlet-crimson; Mr. J. Chamberlain, white, edged with lilac; General Baden-Powell, rich orange-scarlet; and Mrs. Lyons, lilac-blush.

Messrs. Wells and Co., Earlswood, had a group of early flowering Chrysanthemums, including Horace Martin, golden; Rosie, red; Orange Masse; Goacher's Crimson; and Victor Mew, white. Mr. J. Russell, Richmond, had a group of Euonymus and Ivies; Messrs. Laing had hardy flowers, and so, too, had Ladhams, of Shirley Nurseries, Southampton; Mr. C. Turner had Dahlias.

A collection of Apples and other fruits came from Messrs. Hugh Low and Co. Duchess of Oldenburg, Lord Suffield, Loddington, and Allington Pippin were large and handsome. They had also superb Peaches and Plums. Nuts were also included. Messrs. J. Veitch and Sons, Limited, Chelsea, staged a group of pot Pears.

#### THE DOUBLE WHITE POET'S NARCISS.

This, the Gardenia-flowered Narcissus, is variously catalogued. It is the double white poeticus, and is also called Narcissus alba plena odorata—the odorous double white, under which name the Messrs. Webb and Sons include the variety, and through them we are enabled to reproduce the illustration on this page. The lovely sweet-scented, Gardenia-like flowers are much prized for cutting, and growing 15in in height, they have stalks of a useful length. Experts recommend that this Narcissus be planted early in a good, deep, cool soil, not too dry.

Double White Poet's Narciss.

## Currants.

To establish a plantation of Currants, red and white, or black, the bushes should be planted in autumn, just as soon as the leaves have fallen or are falling. Black Currants do well, as a rule, on stiff and moist ground, which ought also to be moderately rich, while red and white succeed on drier ground, which must be well drained, deeply dug, and freely enriched. The distance apart in planting may be the same, namely, 5ft or 6ft apart.

Red and white Currants can be grown as cordons on walls or fences; but black Currants are only profitable grown as bushes. Red and white Currants are pruned the same, but black Currants

distances on the wall or trellis. If grown on a north or east wall the fruit will ripen and hang late, thus prolonging the supply. Currants make abundance of fibrous roots near the surface, hence mulchings of manure are beneficial, and constitute the best method of affording nutriment.

Black Currant bushes will succeed in situations where it may not be advisable to grow other berries, yet they should not have an ill-drained, waterlogged position, but a rich, holding, moist soil. The bushes may be grown with and without short main stems. In the latter case they will throw up strong sucker-like growths from below ground, while in the former all growths have to be secured from the various parts of the permanent branches originating from the central main stem. Both systems may be adopted, but the former is the most general.

The system of pruning differs from that of red and white Currants. It consists in simply cutting out the oldest growths and retaining the young, on which the best crops are produced the following year. There must not be any crowding, and the bushes should be kept well balanced. Retain the growths always at full length. The pruning may be carried out after the crop has been gathered, or it may be deferred until the winter. Do not dig about the bushes, but maintain vigour by liberal annual mulchings. Some of the best varieties of Currants are:—

| Red.            | White.         | Black.              |
|-----------------|----------------|---------------------|
| Fay's Prolific. | White Dutch.   | Baldwin's Champion. |
| Red Dutch.      | Transparent or | Carter's Champion.  |
| Raby Castle.    | Versailles.    | Lee's Prolific.     |
| Comet Red.      |                | Boskoop Giant.      |

—MAN OF KENT.

Japanese Wineberry.

are treated differently. Red and white varieties should be encouraged after planting for the bushes to produce an equal number of stems, which must be considered as permanent. Five or six main stems make a good bush.

The first season they grow vigorously. At the winter pruning shorten one-third, and during the next season side shoots will form, which in July may be summer pruned. At the following winter pruning shorten these to within an inch of main stem, and the leading shoots to 9in or 10in, the annual shortening of the latter being necessary to induce side shoots to push, but after the full extension of the main stems is secured, closely prune back the leaders each season.

The culture of red and white Currants on walls is practically the same as the system adopted for Gooseberries, or as that just detailed for bush Currants, the main stems being secured at equal

## THE WINEBERRY.

This Japanese novelty (*Rubus Phoenicolasius*) can be grown successfully in this country, although some growers do not speak highly of it. The berries, as our illustration shows, are Mulberry-shaped, juicy, and produced in profusion. They make a delicious preserve. As a rule, we find the growth to be robust, and the plants fruit in a very satisfactory manner, the foliage and ruddy stems being strikingly ornamental. Planted like Raspberries, or by a wall, the Wineberry grows well. It is a fine climber for large spaces.

## Raspberries.

Raspberries are delicious fruits, and on good ground are profitable, as if the canes are well ripened there is seldom complaints of a failure of the crop. Good, rich ground is indispensable, and before planting it ought to be deeply trenched and freely manured.

In selecting planting canes it is desirable not to be guided by the strength of the canes, but by the quantity of roots of a fibrous character. Small, thin canes will, therefore, be found to possess the best roots. Plant such as these at the end of October or in November, and in spring cut them down closely to the ground. Nothing is gained by planting stronger canes and expecting them to fruit the first season. They will not do so to any extent, while at the same time vigorous growth of young canes is checked.

Raspberries, if grown in lines, may be planted 1ft apart in rows 5ft asunder. Wires must be stretched along the lines for training the growths upon. Attach them to stout posts fixed at each end of rows. They may be 5ft high. Three lines of wire will be sufficient. Another system of training Raspberries is in clumps of three plants, each clump 3ft apart. Drive a stout stake down in the centre. Each season train in about six of the strongest canes and cut out all weakly. Prune to the height of the wires or stakes. Immediately the crop is gathered each season it is a good plan to cut out at once the whole of the canes which have borne the crop, thus leaving more room for the new canes to become well ripened.

Never dig between Raspberries, for by doing so a vast number of fibrous roots may be destroyed. Strong weeds, if becoming established, may be forked out, and, of course, suckers between the rows ought to be removed. Heavy mulchings of rich manure may, every season, be given to Raspberries during the winter season, and frequent applications of liquid manure, when available, afforded in summer. The liquid will also be beneficial in winter to well established rows.

Like other small fruits Raspberries are subject to the depreda-

**Fuchsia, Western Beauty, over 8ft. high**

(See page 293.)

tions of birds when the fruit is ripe, hence give protection by fish netting, arranging a temporary light framework to support it. Autumn fruiting Raspberries produce fruit on the young wood of the current year, and should be cut down close to the ground in February. Thin out the shoots which result.

*Varieties of Summer Raspberries.*

*Varieties of Autumn Raspberries.*

October Red and October Yellow.

E. D. S.

## Notes on Gooseberries.

Gooseberries are usually profitable to grow, as it is seldom they will fail to fruit, and also to give abundant crops if managed well. Perhaps the largest and heaviest crops may be obtained from bushes grown in a free manner, but cordon trees also bear freely. They are admirable for growing on a wall or fence.

The cultivation of Gooseberries is simple, requiring, in the first place, good ground deeply worked and freely manured. The young trees should be planted in autumn, giving 6ft space every way between the bushes. In planting spread out the roots as far as they will extend, working some good soil among them. They should start strongly into growth in spring, previously to which a little regulation of the branches may be carried out. Shorten them well back the first year if enough branches have not been secured to form a good bush. Thin out weakly growth. When fair-sized bushes have been obtained, further severe shortening should not be practised, but adopt the method of thinning out, leaving plenty of young wood. Some of the best crops are to be grown in this way.

It frequently happens that the trees during the winter are denuded of their buds by bullfinches and other birds, hence it is desirable to protect them from these onslaughts. An effective method is to wind cotton over the bushes, black cotton being the best. Dusting the bushes with lime and soot tends to repel many. Some growers gather the branches together and tie in

a bundle for the winter, while others leave the winter pruning until the last possible moment. The best method of all, but rather expensive in the first place, is to surround the plantation with lin mesh wire netting on iron supports.

*Cordon Gooseberries* are grown against walls or fences. U shaped trees are best for this purpose, and may be obtained ready shaped at nurseries, for the purpose. These should have a short main stem, be furnished with abundant roots, and a main stem must be encouraged from each side. The side shoots they produce in summer must be pruned back in July to five or six leaves, and further shortened in winter. This pruning is practically all that is required, and may be continued annually. Afford liberal mulchings of manure each winter.

The varieties of Gooseberries are numerous, especially the show Gooseberries. They comprise, green, red, white, and yellow. The trees are mostly of spreading growth, and to produce large fruit must be kept thin. The best among the show varieties are:—

| <i>Green.</i> | <i>Red.</i>    | <i>White.</i> | <i>Yellow.</i> |
|---------------|----------------|---------------|----------------|
| Admiration.   | Bobby.         | Antagonist.   | Catherina.     |
| Greenock.     | Clayton.       | Careless.     | Drill.         |
| Matchless.    | Companion.     | Freedom.      | Highlander.    |
| Ocean.        | Dan's Mistake. | Lancer.       | Leader.        |
| Shiner.       | London.        | Nonpareil.    | Leveller.      |
| Telegraph.    | Rifleman.      | Postman.      | Ringer.        |
| Thumper.      | Speedwell.     | Transparent.  | Stella.        |

For general purposes, including culinary and as dessert when ripe, the following are admirable varieties:—

| <i>Green.</i>       | <i>Red.</i>         | <i>White.</i> | <i>Yellow.</i> |
|---------------------|---------------------|---------------|----------------|
| Berry's Early Kent. | Crown Bob.          | Shiner.       | Golden Drop.   |
| Pitmaston Green.    | Ironmonger.         | Whitesmith.   | Early Sulphur. |
| Gage.               | Red Champagne.      | Velvet White. | Rumbullion.    |
| Green Gascoigne.    | Keen's Seedling.    | Hedgehog.     | Yellow Ball.   |
| Roseberry.          | Warrington.         | Early White.  |                |
| Langley Green.      | Whinham's Industry. |               |                |

— E. DENNIS.

## SEA EAGLE PEACH.

Eight model fruits, though shown in a greatly reduced size, are presented on page 291. These were from Mr. W. Strugnell, gardener to Colonel Vivian, Rood Ashton, Trowbridge, Wilts, the first prize in class 45 at the recent show held by the Bath Horticultural Society. The photographer, Mr. E. Rye, of Bristol, added a note when sending the photograph from which we worked saying, "They" (the Peaches) "were of grand colour, as may be judged by their 'coming out' so dark on a bromide print." We should like to note that Mr. Strugnell is a regular contributor to the Journal, and a thoroughly successful, all-round gardener. Sea Eagle was well staged at the Crystal Palace fruit show last week. "It is a handsome late variety, ripening in the end of September and beginning of October, in the open air. It is one of the best for the open air."

**Fruits of Sea Eagle Peach.**

### Clematis Jackmanni.

In the *Journal* for August 21 you try to explain the cause of Clematis Jackmanni growths dying off in answer to "Wyvern, Twickenham." I was much interested, and should like to give my experience. My next door neighbour planted out, from a pot, Clematis Jackmanni against the wall of his house, facing south, in autumn, 1900. It kept what foliage it had when planted, but eventually died down. The owner thought it dead, was impatient, and ordered another to be put in, in autumn 1901. I advised his man not to disturb the one put in the previous year, but to plant at a little distance. He did so. The result is, the one planted in the autumn of 1900 threw up a shoot from the ground this spring, and is now 7ft high, and a pretty sight of bloom on it, while the one planted in 1901 has died down out of sight, similar to the first. It will interest me to note next spring if the second plant throws up from the ground, the same as the one planted in 1900. I have known other varieties of Clematis behave in the same way.—A. B., Hants.

### An Object Lesson.

I recently saw a croquet-lawn made out of a field at the end of last winter, which presented a fine object lesson as to the value of the "top spit" and the infertility of raw soil. The turf was weedy, so it was determined to pare this off and take it away, level the ground, and sow it with grass seed. The ground to be levelled had a fall of about 1ft or more from west to east; and, as, on digging, the soil at the depth of 1ft—a fair light loam—looked (to perhaps rather inexperienced eyes) "just the same" as the top-spit, the whole was levelled by simply spreading it from west to east. It "looked" all right when levelled, rolled and raked, and in good order for the seed, which came up well and evenly in the spring; but really, of course, all the fertile earth had gone from the west side, and there was but little left till half way across. A change of appearance, despite the admirable growing weather, soon came on the young grass, and at August there was not to be seen a really good and healthy plant of grass on the east side, getting gradually worse and worse till on the extreme west it was very poor and yellow, and hardly a plant at all. Of course, this was because it was absolutely "raw" soil on the extreme west, with more and more of the top spit all across the eastern boundary. It would have formed quite an instructive picture for a horticultural class.—W. R. RAILLUM.

### Red Spider on Vines.

Since the discussion between "H. D." and myself a few weeks ago, I have made the following experiment. A small pit containing Crotons on which were some red spider has been vapourised with XL All nicotine compound. The dimensions of the pit are 11ft 6in long, and 6ft wide, and lean to in shape. The height of the back wall is 4ft, and the front, 2ft 6in. By measuring the length by the breadth and the total by the average height—which would be about 3ft—there are roughly 200 cubic feet of space. One of the largest sized vapourisers was used, and sufficient nicotine compound put in the cup to vapourise a house with 5,000 cubic feet of space. The operation was done on a still night, and the plants in it were examined next morning, and most of the spider found alive and active. A plant each of Adiantum cuneatum and Pteris were put in the pit to see if the fumes would destroy the fronds. The Pteris and Crotons were found to be uninjured, but the Maidenhair Fern fronds were blackened. Now, "H. D." will you kindly tell me how you managed to destroy this pest on your Vines by vapourising the vineries with XL All nicotine compound? It would also interest me to know the size of the vineries, and the quantity of nicotine compound used, for I must admit I quite fail to see how you accomplished the feat so easily, unless it is, as you suggest, that we have a class of very "hardened criminals" in this part of Essex. I am sending to the Editor a leaf for his inspection, which I hope he will examine and give his opinion on. But I should like to say I hope "H. D." will not infer that I am attempting to disparage the merits of XL All; far from it, for personally, I think no other preparation equals this for the purpose it was sent out for, viz., the destruction of green and black fly and thrips. Perhaps other readers of the *Journal* will give "H. D." and myself, through these columns, a few words relating to their experiments in dealing with this

pest.—A. JEFFERIES, Moor Hall Gardens, Harlow, Essex. [The red spiders were found to be active on the Codium (Croton) leaf sent to us.]

### Gardeners' Education.

In the course of a letter on this subject the undersigned says:—"In the fulness of my ignorance I had supposed that industry and uprightness, coupled with a thorough knowledge of practical gardening, would fit me for a post as head gardener, but, thanks to your recent correspondents, I now perceive I am quite unfit for the task, and the most I hope for is to obtain a post under one of the learned and superior gentlemen gardeners.—YOUNG GARDENER."

### Indian Pronunciation.

The matter is somewhat trivial, but a wrong impression may have been created which I beg the favour of correcting. In the *Journal of Horticulture* for August 14, page 151, in a note of mine on the Sequoias of California, the word Tuolumne, was incorrectly syllabled. It should be read as if Tu-ol'um-e, the accent being on the second syllable, and the n mute. It is an Indian name, one of the counties of the state being so named, and a grove of Sequoias being so designated. Se-quoy-ah is also an Indian name, and the proper generic name of this tree and of the sempervirens, although often known in England as Wellingtonia. There are but two species, gigantea and sempervirens, both aptly so called, the former from its unrivalled size, and the latter from its tenaciousness, even the woodman's axe and the sheep-herder's fire being unable to destroy it. Cut down a Redwood (S. sempervirens) tree of 15ft to 25ft diameter, and a whole grove of saplings will spring from the stump. Not so with S. gigantea. Let the puny hand of man apply the axe to him, and it is finished! his life's work is done. And what a life! For thousands of years he has weathered the storms of the world, and one may well imagine that the Fallen Monarch, with a whole troop of United States cavalry riding on his trunk would rather be so than to live, like his mate, and see daily, during the summer months, a coach-full of giddy tourists passing through a hole cut for the purpose! Sequoia gigantea is found only in the Sierra Nevada mountains, and then in isolated groups. Sequoia sempervirens abounds in the Coast Range, some fifty or sixty miles west, but running parallel to the Sierras. This range averages about 3,000ft, while the other is more than double, many mountain peaks reaching above 12,000ft, and some above 15,000ft. About seventy-five miles north of San Francisco, in Mendocino County, and on up through Humboldt County, near the coast, are still great forests of sempervirens. Will it "live for ever," or will the greed, the short-sighted greed of man, destroy it also?—LEONARD COATES, Napa, California.

### Staging Dahlias and Other Flowers.

Not once, or twice, but very often, have we expostulated with exhibitors both in print and by speech, in regard to the very slovenly method which many adopt in their staging of blooms for competition at shows. What incongruity they display to have taken serious trouble to cultivate their products for a whole year, it may be, and be at so much attendant trouble and expense in exhibiting, and yet to neglect the final effort. Perhaps it is that some exhibitors cannot stage well even when they try their best. For our own part, however, we think there could be shown ability, were exhibitors on the whole to exert their judgment and their observation more than they do. On this subject we quote from a correspondent, himself a leading Dahlia grower and prizewinner, who writes, saying:—"It seems to me that after all the labour and care required to produce good flowers, it is well worth while to devote the additional time required in setting them up to the best possible advantage. The extraordinary carelessness displayed by some amateurs in this respect spoils the effect of the entire class, to my mind, and I wish you could induce them to take more pains. Apart from this subject, I may add that I have seventy-three plants this year, of twenty-three varieties, which I grow in my back garden, which runs N.-N.W. and S.-S.E., and measures 130ft by 50ft, surrounded by a wall 6ft high. I grow them at the north end with a row of Scarlet Runners across the middle of the garden, and south of the plants for protection against wind. No one touches my ground or plants from beginning to end of the year but myself, and I have no help of any kind, and I may add that I grow these lovely flowers purely for the love of them, and not specially for exhibition, my object being to obtain a constant supply of the finest possible blooms for the table, from mid-July till end of October. I cut them before breakfast every day during the season, and place them in heavy stone vases, in a large, dark airy cellar, where they remain till 7 p.m., when I set them up for the table, carrying them down on trays to the cellar again at bed time, where they remain till the next evening. In this way they keep fresh for from three to five days, according to the temperature."

# NOTES & NOTICES

## A Specimen Fuchsia.

The variety figured on page 291 is Western Beauty, and which was the best specimen plant at the Bath horticultural exhibition this year. The plant figured was shown by Mr. G. Tucker, of Hilpertton Marsh, who is a noted grower there. This plant was over 8ft high. Trowbridge is the centre at which to see these gigantic Fuchsias—living testimonials of patient cultural care.

## The King's Gardens at Windsor.

The alterations at the King's gardens at Windsor, says a daily paper, are now nearly complete. New and commodious apartments have been built for the employés, including bath rooms, bed-rooms, and a recreation room. New glass houses have been added, and up-to-date methods adopted. The magnificent Grape Vine near Cumberland Lodge will yield from 1,800 to 2,000 bunches this year.

## Attar of Roses.

In Eastern Roumelia, the yield of attar of Roses this year is from twenty to twenty-five per cent. less than in 1900. Prices have fallen to an extraordinary degree in the foreign markets. The main cause for regret is that the Rose fields belong to peasant proprietors who are also distillers of the essence, and the ruin of the industry means their undoing. But no attempt to revive it is promising of success, owing principally to the indifference of consumers abroad. Some Frenchmen have started a large distillery at Karlovo, but there does not appear to be much chance of it doing well. The Rose is itself more cultivated than ever, the commoner kinds for massing, the rarer for individual blooms, but the commercial purposes of the queen of flowers have fallen into the background.

## Plants on an Irish Bog.

To "Knowledge" for September, Mr. R. Lloyd Praeger contributes an article which deals with bog vegetation, in the course of which he writes: "The oozy sinuous pools are filled with Sphagnum, and here and there with the Bog Bean, *Menyanthes trifoliata*; the edges of the pools are luxuriously cushioned with a variegated growth of Sphagnum, and these edges are the favourite haunt of two of those wonderful fly-devouring Sundews, *Drosera rotundifolia* and *D. anglica*. In the shallower pools, or on bare mud, the White Beak-rush, *Rhynchospora alba*, grows in tufts, and its farther-creeping relative, *R. fusca*, fills portions of the pools with an erect growth of bright green stems and brown inflorescence. . . . The conditions under which this plant-group lives are remarkable. The spongy crust is perennially saturated with water, which circulates very slowly. In consequence the soil is badly aerated, and the plant-remains which form the crust do not become thoroughly oxidised, and soluble humus compounds remain in solution in water. The plants can with difficulty absorb by their roots water charged with these substances, and thus it comes to pass that while the bog is physically very wet, physiologically it is very dry. In the midst of plenty the plants are actually starving. . . . Exactly the same difficulty, it may be remarked, occurs in salt marshes, where the water is charged with sodium chloride. In both cases the plants meet it in the same way, by checking transpiration, and thus saving up the water which they absorb. Thus they assume characters similar to those displayed by plants of deserts and dry places—xerophytic characters, to return to a term which we have had occasion to use before. These are seen in the smallness of the leaves of the Heath, for example, as well as in the curious backward-rolled character of their leaves, as well as of those of the Cranberry, Crowberry, &c. In other cases the leaves are protected by a thick impervious cuticle or skin, or by a close growth of hairs. Another peculiarity in the conditions under which the bog flora grows is that in the water-logged soil there are no bacteria present, which are so useful in breaking up the complicated nitrogenous compounds contained in the dead plant matter; hence nitrogen as a plant food is scarce. This may help to explain why the Sundews, which are essentially bog plants, have hit upon the extraordinary manner of obtaining nitrogenous food—the capturing, killing and digesting of small animals."

## The Favourite Carnations.

In our paragraph on this subject last week, Germania was referred to as the popular buff variety. Germania, of course, is one of the best yellows, but Benbow should have been mentioned in its place.

## Appointments.

Mr. A. W. Culloch, as head gardener at Heythrop Gardens, Chipping Norton, Oxon. in succession to Mr. Downing, who has resigned owing to ill-health. Mr. Culloch has been for the last ten years head gardener at Newstead Abbey, Nottingham. \* \* Mr. John Williams, for the past five years foreman at Baron Hill Gardens, Beaumaris, has been appointed head gardener to J. Marshall Dugdale, Esq., Llwyn, Llanfyllin Montgomery.

## Proposed European Flower Trust.

Trusts are springing up like mushrooms. The latest proposal of the kind is for the formation of a "floral" trust, the "Société Florale de Cannes." According to the Paris correspondent of the "Financial Times," this company proposes to control the flower market of Europe, and is now soliciting £160,000 from the public to carry the scheme into operation. "Our object," says the prospectus, "is an ambitious one; we desire to form a European natural flower trust." The combine, we are told, already makes an annual turnover of £560,000, on which the profits are said to be enormous.

## Hailstorm in Kent.

Not for many years has a more severe and disastrous storm than that which passed along the valley of the Medway from Tonbridge to Maidstone on Wednesday, the 10th inst., been experienced in England within recent times, except the tornado which devastated Essex five years ago. At East Farleigh there were hailstones 5in in circumference, and in places they lay 18in in depth. In the two villages of Teston and Watlington alone it is estimated that nearly £4,000 damage was done. Colonel Warde, Member for the Medway division, who resides at Barham Court, Teston, had 1,650 panes of glass in his greenhouse smashed; another property owner lost 6,000 Peaches. Hard Pears were cut to pieces by the hailstones, and all trees were stripped of their foliage. It is feared that many of those who suffered loss were uninsured.

## The Canadian Wheat Belt.

Might not English agricultural newspapers do more than they are now doing to keep that magnificent area of Wheat land in Western Canada thoroughly British, by encouraging the emigration of English people to their own territories? Millions of acres of the finest agricultural land in the world are now being offered by the Canadian Government (160 acres ahead, free) to all bona fide settlers, and yet English people are looking on while Americans—who generally know a good thing when they see it—are rushing over the border by thousands to seize the opportunity and, of course, the future reward. It grieves me to see what is now a fine British province being settled so largely by Americans and foreigners. I am not a capitalist, or I would soon take out a few thousand of good British blood to settle upon these fine farming lands—I mean take some of those who are now treading on each other's heels in the Old Country, scrambling for a living? But why don't they go on their own account? Are they afraid they should be going from civilisation to barbarism in a wild, unknown land? Twenty-two years ago I left England, and made, what to me was largely, a plunge in the dark. I have never regretted the step I then took, for I have learned to love Canada and her people, and hope to return again before very long. In the meantime, if my twenty years of experience in Canadian life can throw any light upon the step other people may now be contemplating, I will gladly do what I can to help them by answering any questions, to the best of my ability, provided those who ask them will enclose stamped and addressed envelope to my private address, Alexandra Park Road, Wood Green, N. To-day there is plenty of the choicest land to be had for next to nothing. Five years hence it may be in the hands of aliens. Now is the time if English people are going at all. Why not make up parties of say 100 each and go out and settle by townships in company together? Why not a large party for next March? I am willing to do all I can to help.—(Rev.) GEORGE E. LLOYD, Deputation Secretary (for Canada), Colonial and Continental Church Society, Wood Green, N.

## Peaches and Nectarines.

### Their Classification and Selection of Varieties.

The different varieties of the Peach, distinguished by a downy skin, and Nectarine, known by a smooth skin, are not readily defined from the appearance of the fruit alone. The following classification is that adopted by the late Dr. Hogg, LL.D., in his standard work on the fruits and fruit trees of Great Britain—the well known and popular "Fruit Manual," and is founded on

I.—The flowers being either large or small.

II.—The leaves being serrated without glands, or having either globose or reniform glands at their base.

III.—The fruit having either flesh which parts readily from the stone, or flesh clinging to the stone.

The flowers distinguished as large or small, in some cases nearly approach each other in respect to size, but the small flowers have the petals more of an oval shape than the large, and their colour is different. The large flowers are deeply coloured at the base, whilst their disc becomes nearly white towards the margin. The small flowers, on the contrary, have their petals more deeply coloured at the margin than they are in the middle.

The glands, if any, are situated at the base of the blade of the leaf or on the petiole, but the distinctions between globose and reniform are not always obvious, yet the globose glands are somewhat pedicellate, and raised above the margin of the leaf, whilst in the reniform or kidney-shaped glands they are usually indented in the margin.

The term *freestone* is applied to fruit with a melting flesh or that parting readily from the stone when the fruit is halved; whilst the term *clingstone* is applied to a fruit that may not be so halved, from the flesh adhering or clinging to the stone.

## Societies.

### Royal Horticultural—Drill Hall, Sept. 23rd.

A more interesting or a fuller meeting than that of Tuesday last has not been recorded for a long while. Messrs. J. Veitch and Sons, Limited, filled one side of the hall with a collection of lesser known Japanese shrubs, with dried specimens and photographs of the growing trees to illustrate the lecture on these lesser known shrubs, given by Mr. James Veitch at three o'clock. It may be remembered that Mr. Veitch travelled in the East, and also Australia, &c., some twenty odd years ago. Roses, Dahlias, and early Chrysanthemums, with Gladioli, Orchids, and Ferns composed a bright and varied meeting. The fruit from Mrs. Nix was also seasonable. A committee of the National Dahlia Society met at a quarter to one, and recommended a number of awards to Dahlia novelties, apart from the certificates given by the Floral Committee of the Royal Horticultural Society.

#### Fruit and Vegetable Committee.

Present: Geo. Bunyard, Esq. (in the chair); with Messrs. H. Esling, J. Bates, S. Mortimer, A. Dean, G. Kelf, W. Pope, E. Beckett, G. Reynolds, G. Norman, G. Wythes, W. Poupert, O. Thomas, and Jos. Cheal.

A magnificent collection of fruit came from Mrs. Nix (gardener, Mr. E. Neal), Tilgate House, Crawley, Sussex, about which estate we had some notes in the Journal on September 4th last. The space of tabling occupied was 25ft by 3½ft, and the display was indeed "a highly creditable one," to use the words of the Chairman of the Fruit Committee. Amongst the dishes shown were superb Nectarine Peaches, a handsome dish of Princess of Wales variety, and also Walburton Admirable. Of Plums we noted the newer Reine Claude de Bavay, a greenish Gage, and Prince Englebert. The ordinary Transparent and the Golden were on view, and other Plums as well. Among Apples there were large samples of Mère de Ménage, Lane's Prince Albert,

e, stone to which flesh adheres by stringy matter; f, flesh.

The Queen, Peasgood's, Royal Jubilee, and of brightly coloured samples there were Duchess' Favourite, Manks Codlin, Cellini Pippin, Worcester Pearmain, and Hereford Beefing. Pears and Melons were included. Grapes Appley Towers, Lady Downe's, and Black Alicante were finely finished and large in bunch and berry, each finely thinned. A Silver Knightian Medal was awarded.

Lord Llangattock (gardener, Mr. Coomber), The Hendre, Monmouth, sent two Queen Pines of immense size, weight, and finish, and so superior that a Silver Knightian Medal was awarded.

#### Orchid Committee.

Present: Harry J. Veitch, Esq. (in the chair); with Messrs. J. O'Brien, H. M. Pollett, H. Ballantine, R. Broom-White, Jas. Douglas, E. Hill, W. Cobb, J. Charlesworth, J. Cypher, G. F. Moore, F. G. Thorne, J. W. Odell, W. Boxall, W. H. Young, H. A. Traey, and F. W. Ashton.

A large number of small exhibits were shown by the usual contributors. Messrs. Hugh Low and Co. had some beautiful hybrids, including the charming L. c. x Mrs. J. W. Whiteley, a lovely mauve, with a striking purple lip; also Cattleya x mollis (C. Gaskelliana x superba), of beautiful delicate form, pale mauve

Leaf of Peach with Reniform or Kidney-shaped Glands.

i, indented edge; j, glands.

in colour, with a purple lip. Their C. Martini nobilior is a showy thing, deep ruddy purple, with a handsome violet-purple lip.

Messrs. Veitch contributed L. c. x Bella Langleyensis, a large and noble flower; L. c. x Ophir, L. c. x Bletchylensis var. Lælia Pacuria, with tea-coloured sepals and petals.

Messrs. Charlesworth and Co., Sander and Sons, Sir F. Wigan, Bart., Jeremiah Colman, Esq., H. T. Pitt, Esq., F. W. Wellesley, Esq., and others also brought up specimen plants. Messrs. Stanley, Ashton and Co., Southgate, exhibited one of the most beautiful groups of Cattleya aurea it has been our good fortune to see.

#### Floral Committee.

Present: W. Marshall, Esq. (in the chair); with Messrs. H. B. May, R. Dean, Chas. T. Druery, Edwin Molyneux, G. Renthe, Wm. Howe, Chas. Dixon, Geo. Gordon, Chas. E. Pearson, H. J. Cutbush, J. W. Barr, W. P. Thomson, J. Fraser, H. J. Jones, E. H. Jenkins, Wm. J. James, J. H. Fitt, Geo. Paul, E. Molyneux, E. Mawley, and Jas. Hudson.

We can hardly do justice to the many choice collections

brought forward on this occasion. Roses were exquisitely shown from Messrs. Wm. Paul and Son, The Nurseries, Waltham Cross, Herts. They had a hundred sorts, many of them in great armfuls. Two of these were certificated, namely, *Sulphurea* and *Madame Antoine*. Besides these we may name *Corallina*, *White Lady*, *Enchantress*, *Salmonea*, *Princesse de Sagan*, *Goldquelle*, *Madame Ravary*, and *Chamdeleon*. A fuller note of these may be useful in a succeeding issue.

From L. de Rothschild, Esq. (gardener, Mr. J. Hudson), came another beautiful collection, shown in a new fashion, in vases on a flat open table, and having long shoots scrambling through and among them. Messrs. Paul and Son, of Cheshunt, contributed hardy flowers and Roses; Cutbush and Son had Carnations and hardy border flowers; Hobbies, Limited, sent Dahlias; and other collections of this flower of the moment came from Messrs. Cheal and Sons, J. T. West, Stredwick, Keynes, Williams and Co., and Chas. Turner. From Braiswick Roses were sent, while hybrid *Lobelias* (crosses with *L. syphilitica* and *cardinalis*) were staged by Messrs. Ladhams, of Southampton. These they promised to let us have some notes of, so that more need not be said now.

Mr. Leonard Ching, of The Crescent Nurseries, Edmonton, put up a very creditably grown group of exotic Ferns. In the group were fine plants of the Bird's Nest Fern, also *Gymnogramma chrysophylla grandiceps superba*, *Adiantum speciosum*, and *Lomaria ciliata princeps*.

Messrs. Bull and Sons, of King's Road, Chelsea, were forward again with an exhibit of choice and rare stove foliage plants. Amongst these were typical plants of *Dracæna Victoria*, *Begonia President de Boureuilles*, *Nephtytis picturata*, and *Tradescantia regina*. A F.C.C. was given to *Polypodium conjugatum* from the same source.

Messrs. Veitch, as we mention in the opening lines, contributed fifty or more cut branches of shrubs, representing lesser known kinds of ornamental value, and which have been proved to be hardy in this country. These shrubs were not mere twigs set in vases, but whole limbs and sections, some of them 12ft high, and in the case of some of the climbing plants, they were 20ft in length, attached to poles. Specimens were shown in a mounted state; on papers in front, and between them, and the actual live branches at the back, were large photographs of the trees as growing in the Veitchian shrub nurseries at Coombe Wood. We may name a few of the most striking, which were: *Cornus brachypoda variegata*, a very fine white and green leaved novelty; *Cæsalpina japonica*, a free grower and handsome flowerer; *Polygonum multiflorum*, a beautiful climber; *Clerodendron trichotomum*, becoming well-known, it has large Catalpa-like leaves; *Quercus dentata*, a huge leaved species, which colours well; *Q. serrata* and *Q. acuta*, both invaluable evergreen species with fair-sized glossy, serrated foliage; *Enkianthus campanulatus*, with white, pendant bell-shaped flowers, very lovely; *Styrax Obasia*, already popular. It is a robust shrub, making 3ft of growth in a season. It throws blooms profusely every alternate year. There were also *Betula Maximowiczii*, with broader leaves than any other kind in commerce; *Magnolia Watsoni*; *Stuartia pseudo-Camellia*, with flowers resembling a single white *Camellia*; *Meliosma myriantha*, with long leaves and fine twiggy growth; and lastly, *Acer Miyabei*, named after a Japanese botanist, a very graceful lawn shrub.

Messrs. Wells and Co. sent *Chrysanthemums*, as did Mr. R. Foster, of Nunhead Cemetery, S.E. Mr. Baxter, of Woking, had Dahlias, and Mr. George Prince had Roses. *Populus ontariensis*, mentioned on page 204 of this Journal, is a handsome new variety with huge yellow variegated leaves. Specimens were sent by Mr. J. Carter, Willow Bank Nurseries, Keighley, Yorks. Messrs. Burrell, of Cambridge, contributed a beautiful display of *Gladioli*, in which we noted a large number of unnamed, superior seedlings. Mr. William Pfitzer, Stuttgart, Germany, sent *Montbretia Germania*, a large belled crimson, and *Gladioli*.

#### Medals.

**FLORAL COMMITTEE.**—Gold for group of *Gladioli* to Messrs. Burrell and Co., Cambridge. Silver-gilt Flora for Roses to Messrs. G. Prince, Kingston. Silver-gilt Banksian for Dahlias and shrubs to Messrs. Cheal, Crawley; for garden Roses to Messrs. F. Cant and Co., Colchester. Silver Flora for cut *Begonias* to Messrs. Blackmore and Langdon, Bath; for autumn Roses to Messrs. Paul, Waltham Cross; for Dahlias to Messrs. J. Green and Co., Dereham; for garden Roses to L. de Rothschild, Esq., Acton. Silver Banksian for Ferns to Mr. Leonard Ching, Enfield; for herbaceous plants to Messrs. Paul and Son, Cheshunt; for *Chrysanthemums* to Messrs. Wells and Co., Redhill; for *Chrysanthemums* to Mr. R. Foster, Nunhead. Bronze Banksian for Dahlias to Messrs. West, Brentford.

**ORCHID COMMITTEE.**—Silver Flora for group of hybrid Orchids to Messrs. Jas. Veitch and Sons, Chelsea; for group of Orchids to Messrs. Hugh Low and Co., Enfield; for group of Orchids to Hon. W. Rothschild, M.P., Tring Park, Surrey. Silver Banksian for group of Orchids to Messrs. Stanley, Ashton and Co., Southgate; for group of Orchids to Jeremiah Colman, Esq., Gatton Park, Surrey.

#### Certificates and Awards of Merit.

The following Cactus Dahlias were certificated:—

*Etna*.—Pale purplish-mauve, beautifully fluted and twisted petals; good size. (Award of Merit, R.H.S.) Stredwick.

*Eva*.—A lovely white, of good form, strong in build. (Award of Merit from R.H.S.) Stredwick.

*Coronation*.—The most brilliant scarlet crimson there is. Flowers neat and small. (F.C.C. from N.D.S.) Keynes, Williams, and Co.

*F. H. Chapman*.—One of the finest; petals incurving, orange-red; good centre; large. (Award of Merit, R.H.S., and F.C.C. from N.D.S.) Stredwick.

*H. F. Robertson*.—A brilliant canary yellow, rather slack in build. (F.C.C. from N.D.S.) Stredwick.

*H. J. Jones*.—Clear yellow, with pink. (Award of Merit, R.H.S.) Stredwick.

*Lucifer* (P. W. Tullock, Esq.).—One of the largest and finest Cactus Dahlias of the year, orange-red. (Award of Merit from the R.H.S.)

*Mabel Tulloch*.—A sweet rose-pink with yellowish centre. Flowers moderate in size, incurving, and neat. (F.C.C. from N.D.S., and Award of Merit, R.H.S.) Stredwick.

*Minnie West* (J. T. West).—Not found.

*Miss T. Cherry*.—A.M., R.H.S.

*Raymond Parks*.—Bright scarlet-crimson; good size and fair form of petal. (Award of Merit, R.H.S.) Stredwick.

*Tesuvius*.—A yellow ground Fancy Cactus, striped bright crimson. (Award of Merit, R.H.S.) Stredwick.

*W. F. Balding*.—A richly-coloured bloom, deep yellow, with ruddy basal petals; large, the petals inclined to broaden. (Award of Merit, R.H.S.) Stredwick.

*Winson*.—A.M., R.H.S.

Two single Dahlias:—

*Dahlia Serita* (Cheal and Sons).—A rich amaranth single, with lighter tips. (Award of Merit from R.H.S., and F.C.C. from N.D.S.)

*Dahlia Snodrop* (Cheal and Sons).—A pure white single with a showy orange disc. (Award of Merit, R.H.S.)

Also the two following Show varieties:—

*Show Dahlia A. M. Burnie*.—A good flower of a cinnamon shade. (Award of Merit, R.H.S.) Mrs. St. Pierre Harris, Orpington.

*Show Dahlia Mr. W. Treseder*.—A handsome Show bloom, already described. (Award of Merit, R.H.S.)

*Cattleya Grossi*.—Of the Acklandi type. The lip is bright purple, the sepals and petals dark brown. (Award of Merit.) Hugh Low and Co.

*Cattleya* × *Iris*.—The parentage is *C. bicolor* and *C. aurea*. A remarkable flower, large and bold. The lip bends downwards and expands broadly in front, being coloured bright amaranth. The wavy petals are ruddy brown, and the narrower strap shaped sepals are the same colour. (F.C.C.) Charlesworth & Co.

*Gaillardia ceculata Sulphur Gem* (B. Ladhams).—A pretty soft buff yellow with dark disc. (Award of Merit.)

*Liatris graminifolia*, var. *dubia* (Wallace & Co.).—Grows 6ft to 7ft high, and proportionately large and showy. Broad spikes of bright, purplish mauve flowers. (Award of Merit.)

*Lilium Browni*, var. *chloraster* (J. Veitch & Sons, Ltd.).—This variety is not so long in the tube as the type, nor fragrant. It is almost white with a yellowish throat. A stately late-flowering Lily and quite hardy. Grows 4ft.

*Lobelia* × *Andrew Barlow* (B. Ladhams).—A rich deep reddish-purple. (Award of Merit.)

*Lobelia* × *Purple King* (B. Ladhams).—A hybrid between *L. syphilitica* and *L. cardinalis*. It is hardy and robust. The flowers are violet purple. (Award of Merit.)

*Miltonia Regnelli*, *Gatton Park variety* (J. Colman, Esq.).—The firm little flowers are very showy, with deep buff segments and purplish lip. The leafage is very much like that of an *Oncidium*. (Award of Merit.) Jeremiah Colman, Esq., Gatton Park, Surrey.

*Polypodium conjugatum* (Bull & Sons).—This certainly is one of the most distinctive species that have appeared for a long while. The fronds are 5ft to 6ft long, bright decided green, with long, slender pinnules divided right to the black midrib. An elegant and invaluable novelty. (First-class Certificate.)

*Rose, sulphurea* (William Paul & Son).—A beautiful sulphur yellow decorative bedding Rose, a free bloomer and good autumnal, with glossy dark leaves and crimson shoots, not liable to mildew, and a good doer. (Award of Merit.)

*Rose, Madame Antoine Man* (William Paul & Son).—Strong and handsome in the bud, a beautifully rounded, full flower. The centre is creamy, the lower or guard petals being rosy-lilac. Very strong; a promising new variety. (Award of Merit.)

#### Royal Caledonian Horticultural.

On Thursday, September 11, we were enabled to give a brief telegraphic summary of this fine exhibition, held in the Waverley Market, Edinburgh. We have now the pleasure to refer more in detail to some of its leading features. The exhibition, as formerly stated, was highly successful, inasmuch as the great area of the hall was filled with exhibits that, on the whole, were

of very high quality, notwithstanding the many difficulties with wind and weather that Scottish gardeners have this season had to contend with. Seldom, perhaps, has the proverb been more amply justified that Scottish weather consists of "nine months of winter and three months of damned bad summer," than in the present year, yet that perseverance which overcomes so many difficulties did not materially detract from the quality or attractiveness of the autumn show.

The fruit and Grape classes are always a very prominent feature at Edinburgh, and gardeners gather from all parts of the country to see the high-water mark of attainable perfection. The centre of attraction was undoubtedly the dessert table, 10ft by 4½ft, for not more than sixteen dishes chosen from a collection laid down in the prize list, and decorated with plants or flowers at the discretion of the competitor (Orchids excluded). There were in all four very meritorious tables shown, and as the fruit and floral portions had to be treated as separate prizes, the judges had a difficult task set them. After long and careful scrutiny, Mr. Dawes received the coveted first award for the fruit portion by only half a point in advance of his Scottish rival, Mr. Kidd, of Carberry Tower, the respective points being: for Mr. Dawes, 93½ points out of a possible 121, and 93 for Mr. Kidd out of a possible 112. Curiously enough, this showed the second-prize man to have gained 84 per cent. of his points, against 77 per cent. for his successful rival. Many onlookers thought that, with such a very close contest, an equal first would have best met the case. Mr. Dawes was strongest with Peaches, Nectarines, Melons, Figs, &c., while his Grapes, though fine, were not quite up to those of Mr. Kidd. Mr. Cairns, of Balruddery, was a very good third, and the unplaced table of Mr. Smith, Oxenford Castle, was also very meritorious.

In the decorative division of the prize, Mr. Kidd left no doubt, his exhibit being in this respect much the finer, gaining 24 out of the 28 points, though, in our opinion, the decorating in this and some of the other tables was overdone. Mr. Kidd's centre épergne was beautifully and lightly done with *Gloriosa superba*, Sunrise Tea Roses, Lily of the Valley, Francoa, &c. Mr. Smith, of Oxenford, was awarded second for decoration, while Mr. Dawes had to be content with third place, the flowers being of a commoner description and the effect slightly heavy.

In the competition for ten dishes of fruit, Mr. Dawes and Mr. D. Murray, Culzean Castle (who, by the way, was appearing for the first time, carrying his newly awarded honours as Neil medallist with characteristic modesty), had a very hard tussle, but the premier position was finally awarded to Mr. Dawes. Mr. Smith, Oxenford, was a good third. Mr. Dawes' Grapes in this competition outweighed, in the eyes of the judges, the very handsome Smooth Cayenne Pine in Mr. Murray's collection.

For collections of hardy fruit grown in Scotland, Mr. Day, Galloway House, was an easy first, his Pears, Plums, and Apples being very fine. Mr. Binnie, North Berwick, and Mr. Harper, Bankfoot, Perth, were second and third respectively with good assortments.

For the twelve dishes of orchard house fruit (Grapes excluded) there were five entries, the victor being Mr. James Beisant, Castle Huntly, with very handsome dishes of Pears *Béurre Diel* and *Doyenné du Comice*, wonderful Peasgood's Nonesuch and Alexandra Apples, and good Nectarines, Peaches, and Plums. Mr. Dawes had to be content with second place, but showed excellent material.

The Grape classes were, indeed, a great feature of the show, and, though Edinburgh people have sometimes seen, perhaps, a fully larger display, they have seldom, if ever, seen a better. The chief class for six bunches was very keenly contested, and it was gratifying that finish and quality carried the day. Mr. Lunt, Keir Gardens, maintained his well-earned reputation as one of the very foremost Grape culturists of the day, with splendidly grown and beautifully finished bunches of Muscat of Alexandria, Black Hamburgh, and Madresfield Court. Messrs. Buchanan, Kippen, in this competition had to give place to Mr. Lunt, but their exhibit was well worthy of their reputation as champion market growers. They staged Muscats, Alicantes, and Black Hamburgh. In the class for four bunches, Messrs. Buchanan were first amongst the eight competitors, with beautiful samples of Alicante, Cooper's Black, Alnwick Seedling, and Diamond Jubilee. Mr. Day, Galloway House, followed very closely with Muscat of Alexandria, Mrs. Pince, Muscat Hamburgh, and Mrs. Pearson. Many would not have been surprised if the premier ticket had been on Mr. Day's stand. Mr. Beisant was an excellent third.

For two bunches of Muscat of Alexandria Mr. Day was awarded first, but followed very closely by Mr. Kidd, whose Muscats are always well to the front, showing that, as a high-class Grape culturist, he is no "kid." Mr. Green, Grinkle Park, Yorks, was third with large but rather poorly coloured bunches. For one bunch Muscats, Mr. Wann, gardener to Lord Balfour, the popular Scottish Secretary, was first with a very pretty bunch, with Mr. Green and Mr. Cairns second and third.

The Council of the Royal Caledonian give special encouragement for the cultivation of Black Hamburghs, and on this occasion their efforts were well rewarded, there being sixteen com-

petitors for two bunches, and twenty for a single bunch. In both classes, Mr. Lunt proved victorious with large, well finished, and beautifully coloured bunches. Mr. Fairholm, Alloa, being second in both classes—a highly creditable feat. Messrs. Buchanan were first for Alicantes, as also for Alnwick Seedling, Mr. Day and Mr. Leslie, Piteullen, being second in the respective classes. Mr. Leslie, who is well known as a high-class cultivator, was on this occasion not so much in evidence as usual. Mr. David Murray was first for Lady Downe's, and Mr. Glen carried the premier prize for Madresfield Court, leaving Mr. Lunt in second position. For a new Grape, Messrs. Buchanan were first with Diamond Jubilee, and Mr. Lunt second with Prince of Wales, labelled a "Sport from Mrs. Pince." In the "Any other Class," Mr. Nicol, Forgandenny, was first with a beautiful bunch of Gros Maroc; second, Mr. Waldie, of Dollar. For one bunch any other white, Mr. Mathieson, North Berwick, gained the first award with a most attractive bunch of Buckland Sweetwater. For the finest flavoured black, Mr. Lunt was first with Muscat Hamburgh; Mr. Beisant second with Black Hamburgh. Finest flavoured white: Mr. Galloway was first with a small bunch of Muscat of Alexandria. For the finest bloomed bunch of Grapes, Mr. Sutherland, Polmont, was first with Cooper's Black.

Passing from Grapes to hardy fruits, the various classes showed that, while there were many good samples, the season had been against growers, size and colour being conspicuously absent, and some growers could not exhibit at all. For twelve varieties of Pears, Mr. Findlay, Uckfield, Sussex, was first with creditable specimens of popular sorts, Mr. Gibson, Marlow, second, and Mr. Dawes third. For six varieties, grown in Scotland, Mr. Galloway, gardener to the Earl of Wemyss, at Gosford, was first, Mr. Greenlaw, Kilmun, second, and Mr. D. Murray third. A great number of single dishes were shown in competition for twenty separate classes, but our space is too limited, and life is too short, to enter into details.

There were also a great array of dishes of Apples, of which the same may be said, there being no fewer than fifty classes of Apples. Surely many of these classes could be profitably omitted, anything of special value being sure to come to the front in the collections of dessert and cooking varieties. For twelve varieties (open), Mr. Whiting, Hereford, was first, Mr. Tolhurst, Polmore, Sussex, second, and Mr. Koe, Hereford, third. For eight varieties grown in Scotland, Mr. Day was first, Mr. D. Murray second, and Mr. Nicol, Forgandenny, third. For six varieties, Mr. Dawes was first and Mr. MacKinlay second.

A very fair display for the season was made in the classes for Strawberries, Raspberries, Gooseberries, Currants, &c.: the dish of Fay's Prolific Red Currant from Mr. Smith, Oxenford, was specially good. Superlative Raspberries from Mr. Hunter, Galashiels, were also noteworthy.

For Melons, Mr. Hughes, Peebles, and Mr. M. Hendry, Balerno, were first respectively for green and scarlet fleshed varieties. Peaches were a very fine lot, Mr. Glen, Larbert, being first with beautiful Sea Eagle, Mr. Brown, Dunnikier, second with Barrington, and Mr. Dawes third. Mr. Dawes gained first for Nectarines, Mr. Lunt second. For Gages, Mr. Dawes was first and Mr. Cairns second. Twelve purple Plums (not Gages): Mr. Findlay was first and Mr. Dawes second. Twelve red Plums: Mr. Findlay was also first, and Mr. R. G. Sinclair second. Collection of dessert Plums: Mr. MacKinlay first, Mr. Harvey second, and Mr. Dawes third. Collection of culinary Plums: Mr. Gibson first, Mr. Harvey second, and Mr. MacKinlay third.

**Plants.**—For groups of plants there were only two competitors, and these not of outstanding merit. In this department the veteran Mr. M. MacIntyre, The Glen, Innerleithen, was not at this show, he having gone for a long holiday to the Fiji Islands. His plants were missed. The two groups were not of outstanding merit, but that of Mr. Knight, Lenzie, was a long way the best. In a neat, loose arrangement were very well grown highly coloured Crotons and attractive *Dracenas*, *Liliums*, *Gloxinias*, *Orchids*, &c., with a few graceful Palms. Mr. Geo. Wood, Oswald House, was second, but on this occasion was not up to his usual mark, and flatness and want of brightness being much noticeable in the group.

Plant growing does not seem to advance in the immediate neighbourhood of Edinburgh, as we observed most of the notable plants staged were from a distance. For four stove or greenhouse plants in bloom, Mr. Thorn, Balerno, was first with fair plants of *Lapageria alba*, *Vallota purpurea*, a *Pancratium fragrans*, and a double *Petunia*. Mr. Wood was second. For one flowering plant, Mr. G. McKenna was first, with a handsome *Statice*. For four Orchids, Mr. Sharp, Freeland, Perth, was well first with two *Odontoglossums*, a *Vanda tricolor*, and *Cattleya velutina*; second, Mr. Wood. Mr. Sharp was alone for three *Cypripediums* and for one Orchid.

Ferns were well shown, Mr. Lunt being first for four *Adiantums* with large handsome specimens of *concinnum*, *cuneatum*, *digitatum*, and *grandiceps*. Mr. R. Stewart, Murrayfield, a good second. For four exotic Ferns, Mr. Stewart was first with very handsome plants, which attracted much attention. British Ferns were well shown, Mr. J. C. Brown's first prize nine being

most attractive. Fuchsias made also a good display. For foliage plants, Mr. Lunt was a long way ahead. His six specimens were splendid first-rate examples of good cultivation, prominent among them being Anthurium Veitchi, Dracæna Doucetti, and Croton Houldsworthi. Mr. McKenna was first with two fine Dracænas—Doucetti and Lindeni, and for two Crotons. Mr. Lunt was first with two splendidly coloured bushes in tubs. Mr. Wood scored for specimen Palms. Mr. Knight was at the front for table foliage plants, and Mr. Lunt for table Ferns.

*Cut Flowers.*—These were wonderfully shown for the season, especially after the storm of the 3rd. Dahlias were well shown in the gardeners' classes, Mr. Thos. Robertson gaining the first prizes for twelve Show and Fancy varieties, and also for twelve Cactus varieties. For six Show Dahlias Mr. Sutherland was first, and for six Cactus varieties the Rev. H. G. Smith, Duns, led. The principal show of Dahlias, however, was from trade growers, and in the nurserymen's competition Messrs. Campbell and Son, of Blantyre, were first for a collection occupying 7ft by 5ft, with a very fine lot, also for eighteen bunches of Cactus Dahlias and for twenty-four Show and Fancy Dahlias. Mr. Gold, Wishaw, and Mr. Sutherland, Lenzie, also showed Dahlias well. Gladioli were not numerous, but they were good. The thirty-six staged by Mr. Muir, Prestwick, were a marvellously fine lot, while those in the gardeners' and amateurs' classes were of first-rate quality, Mr. Bennett, Tweedmouth, and Mr. Lawrie, Prestwick, gaining first and second prizes respectively.

Sweet Peas were an extensive and beautiful exhibit, some of them very fine, but some weather stained. For twelve vases, Mr. A. Shakelton, York, was first, and also for six vases; Mr. Duncan, Duns, being second for twelve, and Mr. Malcolm, Duns, for six. Mr. Shakelton was also first for twelve vases decorated with any foliage or grasses. For six vases of Carnations, Mr. D. Oliver, Hawick, was first, and Miss Duncombe, Newton, York, second.

Hardy herbaceous perennials were well shown, the first prizes for both twelve and six going to Mr. A. Bryden, Innerleithen, with beautiful, well arranged lots, conspicuous among them being fine specimens of *Eucomis regia*, *Sidalcea Listeri*, and *Francoa appendiculata*. Annuals were well shown, but arranged in close, dumpy bouquets, have not the appearance they ought to have. The secretary worthily tried to introduce a better state of things by exhibiting six loosely arranged vases, but the judges need educating, and awarded the prizes to the tight bunches, which show no natural habit or beauty of the flowers. Mr. A. Dickson was first for twelve varieties. Pansies, Phloxes, Asters, &c., were well shown. Chrysanthemums were a good show, both in blooms and bunches. The twelve blooms from Mr. Baird, Cambus, were splendid flowers, but were too reminiscent of winter to be really appreciated.

*Roses.*—The leading feature in cut flowers was the Roses, a better September exhibition of the queen of flowers having probably never been seen before. In the nurserymen's section the competition was very keen, and exhibits of great merit. The main awards have already been reported. For twelve scarlet or crimson Roses, Messrs. Dickson and Sons were first with Charles Lefebvre, Messrs. Croll second. Twelve pink Roses, Messrs. Croll first with Mrs. John Laing, Mr. Hugh Dickson second with the same variety. Twelve any white Rose, Messrs. Croll first with Bessie Brown. Best collection of Roses on a table 5ft by 5ft, Messrs. Cocker, Aberdeen, were easily first with a highly meritorious collection, beautifully arranged; Messrs. Croll were second with fine blooms, more formally set up. For twelve vases Roses (H.P.'s excluded), Messrs. Ferguson, Dunfermline, were first with very fine blooms well set up. Mrs. J. W. Grant was very prominent, and Madame Ravary, a deep orange yellow, of recent introduction, is very promising.

In the Roses classes for gardeners and amateurs there was a good, but not a large, display. For twelve blooms, Mr. L. Black, Carenden, was first, and the veteran rosarian, Mr. Parlane, Helensburgh, second. For twelve Tea Roses Mr. Parlane was first, and Mr. Bennett, Helensburgh, second. Roses in vases were well shown, all the first prizes being gained by Mr. A. E. Todd, Musselburgh, for vases of good blooms, most artistically placed on view. His vase of Caroline Testout was most beautiful. These were an object lesson to all other exhibitors, both trade and private, as to how to arrange Roses in vases for effect.

*Vegetables* were a large show, though some were not quite up to the usual mark through the coldness of the season. The collections were referred to in our issue of September 11. In the single dishes there were excellent exhibits of Tomatoes, Cauliflower, Leeks, Onions, Potatoes, Cucumbers, Carrots, &c., but space forbids us to particularise.

Reference may be made to Messrs. Sutton and Sons' exhibit, which was very massive and showy, if a trifle stiff and somewhat crowded, but it was an embarrassment of riches. Their specimens of their vegetable specialities were specially worthy of note. Their strains of fringed Begonias, six months from seed, were very beautiful. Celosias were also fine. Their noted strains of Asters were not in such good bloom as last year, but showed high quality.

The group of fruit trees in pots from Messrs. Rivers, of Saw-

bridgeworth, was the most educative feature of the exhibition. It is the first time that gardeners in the north have had brought before them in this way the successful manner in which fruit trees can be grown and fruited in comparatively small pots, and the Gold Medal bestowed on the collection was a worthy compliment to the southern firm for the public spirit shown in coming so far from their base of operations.

Messrs. Laing and Mather's Carnations were a very notable exhibit for variety and quality, but specially for the tasteful manner in which they were arranged. All stiffness was abandoned, and the handsome glasses were most elegantly filled. The genial head of this enterprising firm, Mr. Mather, is to be complimented on the success of this decorative experiment. Some of the firm's novelties were prominent, such as Duchess of Roxburghe, Sir Waldie Griffith, &c. A first-class certificate was awarded to a new yellow Carnation, Lady Nora Fitzherbert, of very dwarf and proliferous habit. This should be a good bedder.

*Tulipa retroflexa.*

The hardy border flowers exhibited by Messrs. Cocker and Sons, Aberdeen, were a whole show in themselves—a large stage, 40ft in length, filled with most beautiful hardy flowers of all the choicest sorts, *Liliums*, *Gaillardias*, *Montbretias*, *Pyrethrums*, *Eryngiums*, *Chrysanthemum maximum* varieties, &c. They received a certificate for a beautiful deep-rose Carnation.

Messrs. Dobbie and Co., of Rothesay, had also a very beautiful table, largely of Cactus Dahlias, but very varied, with many beautiful autumn flowers. Goacher's crimson early Chrysanthemum was prominent and bright, also the yellow form of Marie Masse Marigolds, for which the firm are famous; were also prominent, as were a collection in vases of choice varieties of Roses, among which may be noted the little known Gus' av Regis, pale yellow, beautiful in bud; Billard et Barr, a deep orange Tea, much finer than W. A. Richardson; Madame Pernet Ducher, pale yellow; Liberty, the new crimson; Marquis of Salisbury, &c. It is a boon to see Roses in vases with their stems, to show the habit of the varieties.

During the two days of the exhibition about 13,000 visitors passed the entrance gates, and it is to be hoped that the cash receipts will be encouraging to the executive and to the energetic and talented secretary, Mr. Murray Thomson, who spared no pains to perfect every arrangement and to make everything pleasant and agreeable to both exhibitors and competitors.

## TULIPA RETROFLEXA.

To be restricted to only one species or variety of Tulip, if that were possible, would be particularly grievous, but if it came to a choice of only one, I think that *retroflexa*, the golden, would be the subject of my love. Its beautifully turned segments and lovely curving base, of a bright and clear yellow, are more chaste in my eyes than words can describe. It is undoubtedly a noble Tulip, classed amongst the cottage varieties, and seems to grow quite as freely as any other Tulip in a friable sandy loam. An open but sheltered situation should be selected for this species. The illustration is one of Messrs. Veitch's (Chelsea), and shows the flower well. In a cut state it remains fresh for ten days.—D.

### Fruit Forcing.

**LATE PEACH TREES.**—When the fruit is gathered the trees will need to have the shoots thinned where too crowded, and those which have borne fruit and are not required for extension can be cut out to a successional shoot at the base; this, with free ventilation, will assist in ripening the growths, which is of primary importance as regards next year's bearing. In cold localities, and the wood strong, it may be necessary to employ gentle fire heat in dull weather. Avoid a dry condition of the border. The trees must not lack water at the roots, and yet drier condition of the soil is advisable whilst the fruit is ripening, but anything like dryness to the extent of distress to the foliage interferes with the formation and maturation of the buds, and may seriously prejudice their retention on the trees, which simply cast them because imperfect, or impaired a vitality from various causes. Some of the late Peaches, as, for instance, Walburton Admirable, Golden Eagle, and Comet, will require gentle fire heat in cold localities to ripen them thoroughly. An occasional syringing will be necessary for trees from which the fruit has been gathered.

**UNSATISFACTORY TREES.**—Where the trees cast their buds, do not set the fruit well, or fail to stone and finish their crops satisfactorily, something is amiss either in the management or with the roots. Either the roots are too deep or the soil is too rich and loose, unsuitable material, or imperfectly drained. Trees in an unsatisfactory condition should be partially or wholly lifted as soon as the wood is mature. If this be done whilst the trees are in leaf, the house should be shaded before commencing operations, and the old border made evenly moist. In removing the soil commence at the point most distant, and work towards the trees, and when it has been cleared away the exposed roots should be drawn aside, damped, and covered with mats whilst the drainage is being attended to. This should consist of 12in thickness of rubble, largest at the bottom and smallest at the top, and if a covering be placed on of old mortar rubbish, freed from all sorts of wood, it will make all secure and be a source of calcareous matter. A drain below the rubble must be provided to carry off all water, and it must have proper fall and outlet. Strong loam is most suitable. If inclined to be light, add a fourth of clay marl, as fine as practicable; if very strong add a fourth of road scraping, and in any case a tenth of old mortar rubbish, taking care to remove laths and other pieces of wood. A cartload of wood ashes may be added to every ten cartloads of the compost, with about 2cwt of crushed bones, and a similar amount basic cinder phosphate, the whole well incorporated and put in the border firmly, and the roots, after having any fibreless portions shortened with a knife, must be spread out evenly over the bed, placing them in layers, and all within the top foot-depth of the border, the topmost roots not being covered deeper than 2in or 3in. The border need not be more than 24in deep, and in no case wider than the width or height of the trellis. A good watering will be needed to settle the soil about the roots. The shading must remain on if the weather be bright, and afford ventilation by the top lights only, syringing the foliage lightly in the morning and afternoon until it is seen that the roots are working in the fresh compost, when the shading may be removed and the house opened. Trees so treated rarely cast their buds, the flowers or fruit set well—indeed, the operation of lifting is the only method of successfully treating trees in an unsatisfactory condition from root causes.

**LATE MUSCAT GRAPES.**—Where these are not thoroughly ripe a rather warm atmosphere by day with a free circulation of air, and enough at night to prevent the deposition of moisture on the berries, will be needed some time longer, indeed, it should be continued until the Grapes are finished, when a gradual reduction of temperature must take place, about 50deg by artificial means being necessary for Muscats after they are matured. Moisture must be kept down by the bracing atmosphere, a pent up air with a sudden increase of temperature from sun being sure to induce moisture to condense on the berries, which will cause them to spot, and then the Grapes will speedily decay. A little clean, dry straw or matter spread on the inside border is useful in preventing moisture rising. The Grapes in these will now have finished, but it is well to make sure that such is the case quite up to the shank of the berries, before ceasing the needful aid from fire heat. All late thick-skinned Grapes require a long time to mature after being apparently ripe, consequently a temperature of 55deg should be allowed, with a rise of 5deg to 10deg by day, and a circulation of air until the foliage is giving indications of falling,

when a temperature of 50deg will be sufficient. The inside border must not be allowed to become too dry. If necessary, water in the early part of a fine day, and cover with a dry mulch as a safeguard against damp, and a repetition of the watering. Outside borders will be quite damp enough from the recent rains, and should be covered with lights preferably, or some other means employed to throw off heavy soaking rains. Where the Grapes are not finished they must be treated similarly to late Hamburgs in order to mature.

**LATE HAMBURGS.**—These finish and colour when it is almost hopeless to do anything more with the thick-skinned varieties, but they are best finished as soon after this as possible. When not ripe they should have a temperature of 60deg to 65deg at night, and 70deg to 75deg in the daytime, with a circulation of air constantly, not allowing the border to become dry, but giving a good watering if they are only partially advanced in colouring, and mulch with short dry material. Only restrict the laterals to prevent overcrowding, but after the Grapes are finished avoid further extension, yet not reducing the foliage too much, as this assists Hamburgs to keep their colour.

### The Kitchen Garden.

**LETTUCE.**—Lettuce plants, intended to be planted out, should now be in their permanent quarters, so that they may become well established before winter. Lettuce will succeed very well in all but the dampest positions and heaviest soil. Well drained soil suits it best for the winter season. It is found desirable to plant in sheltered places under walls, these positions affording some natural protection. Birds are found to be troublesome by pecking at the leaves, which, of course, prevents growth. In this case, cover the plants with netting or stretch black cotton over them. Frequently hoe among the plants, and dust lime or soot between to keep down snails.

**SPINACH.**—The winter Spinach should have the soil between the rows kept clean, and any densely crowded patches of plants should be thinned. At this season the plants do not require to be thinned too far apart. Remove weeds, and lightly hoe the spaces between the rows.

**CELERY.**—A few more rows should be earthed finally, deferring the operation with the latest rows for a few weeks, so as to give them time to complete their growth. A convenient method of earthing consists, first, in lightly drawing the leafstalks together, so as to well enclose the centres or hearts of the plants, securing them in position with raffia grass ties; then break up the soil on each side of the rows, making it fine and crumbly. Arrange the soil in a line on each side of the rows, and work it round the plants with the hands. At the same time, form a good base on which to place more soil. None should be worked round the plants higher than the centres, except at the final earthing. Earthing can only be satisfactorily done when the weather is dry, as well as the plants. Soil that is more than ordinarily retentive, wet, and heavy, may not be suitable for earthing. The introduction of some light material, such as coal ashes, may be admitted for placing directly round the plants.

**POTATOES.**—The lifting of the Potato crop continues to be a most important operation. Dry weather must be chosen, if possible, digging up no more tubers in one day than can be sorted, dried, and stored. Select clean, sound, medium sized tubers to save for seed. Store these singly in shallow boxes, which may be stood on a shelf in a cool structure. The large tubers for use, after being thoroughly dried, may be placed in bags, boxes, or in a heap in the store room, covering them over entirely with straw to exclude light. Where the crop is more than usually productive, a portion should be clamped in the open, covering with straw and soil.

**TOMATOES.**—The fruit secured on the outdoor plants will, in many cases, fail to fully ripen; hence some glass lights ought to be placed in front of the plants to give them extra warmth and forward the colouring. When the fruits do commence to colour they may be cut and finished under glass or in a warm kitchen. The small, green fruits may be utilised in pickling.

**ONIONS.**—The crop of summer Onions, if not harvested, should now be pulled up and dried in the sun and air. If wet, transfer them under cover, but do not store them until thoroughly dry. A little thinning of the seedling plants may be given the rows of winter Onions; also remove weeds and lightly stir the soil.

**CABBAGE.**—Augment the number of plants, if necessary, which have been placed out for the spring supply. Strong and useful plants can be secured from the seed beds. Lift with a fork or trowel, and plant without loss of roots, a foot apart in rows 2ft asunder. Plants pricked out have grown strongly, and these ought also to be lifted, with ample soil adhering, planting with a spade. Afford these more space between the plants in the rows. Stir the soil with the hoe as soon as the Cabbages are established, and continue to maintain an open, clean surface, which will promote steady growth.—EAST KENT.

## TO CORRESPONDENTS

\* \* All correspondence relating to editorial matters should be directed to "THE EDITOR," 12, Mitre Court Chambers, Fleet Street London, E.C. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense.

**LEAVES OF BEGONIAS DISFIGURED** (A Reader, Cambs.).—The leaves of Gloire de Lorraine are infested by the Begonia leaf-rust mite, *Tarsonymus Begoni*, a very pernicious creature, as by its piercing of the tissues and the mode of life of the larvæ causes leaves to become crumpled, stunted and disfigured, the under side having a rusted appearance, and sometimes they are so bitten and poisoned evidently, that they often fall off to a great extent. The leaves of Begonia weltoniensis are infested by the same pest, but in a less degree, the mite not being so fond of this species as of the more fleshy leaves of Gloire de Lorraine. The only thing as yet found of any use is spraying or dipping in tobacco water, made by placing an ounce of the strongest shag tobacco in a vessel and pouring on a quart of boiling water, covering close, and leaving until cool, then straining and spraying on the under side of the leaves, the plants being held upside down, or in case of a large number of plants more tobacco water may be made of a similar strength so as to admit of dipping them. The spraying or dipping should be repeated two or three times at intervals of about a week.

**CUCUMBER AND TOMATO PLANTS DYING** (T. P. R.).—The Cucumber plant has the leaves affected by leaf-spot fungus, *Cercospora melonis*, but the sudden collapse of the plant is due to a stem affection closely allied to sleeping disease in Tomatoes, *Fusarium Lycopersici*, which infests the vascular bundles, and prevents the flow of sap, hence the sudden collapse of the plant. The Tomato stem certainly has some "black stripe," but the cause of the collapse is sleeping disease. Probably both the affections of the stems is only a form of *Fusarium solani*, most likely encouraged by the high-feeding conditions under which both Cucumbers and Tomatoes are grown, the former being treated more like aquatics than under rational conditions befitting plants that never thrive in deluged soil, and require naturally a well aerated atmosphere. There certainly is not any remedy for the sleeping disease, and the best preventive is to treat the compost with a mixture of 8 parts basic cinder phosphate and 3 parts refined kainit, sprinkling on the freshly cut turfy loam at the rate of 4oz per square yard as the turf is stacked in autumn per 3in thickness, or on each layer of turves as placed on grass side downwards. In cutting down the turf stack it should be from top to bottom, and mixing the whole well before use. For the Cucumber leaf-spot there does not appear any remedy. Bordeaux mixture not acting as either preventive or repressive, and the removal of affected leaves not retard the advance of the fungus, it attacking the very young leaves and preventing further profitable growth.

**FORCING LILY OF THE VALLEY** (R. S.).—Either home-grown or imported Berlin crowns should be used for early forcing, and for very early work retarded crowns should be employed. They should be placed rather thickly in pots or boxes, and a little light soil or cocoa-nut fibre lightly shaken amongst the roots, but not over the tops; they should be covered with moss. Another plan is to insert them similarly in propagating frames and pot them, if so desired, as they come into flower. The roots do not grow during this period, consequently it is immaterial which method is adopted. Plunge in a bottom heat of about 85deg, and if possible maintain a top heat of 70deg to 75deg. This encourages the production of leaves and flowers at the same time. If pots or boxes are used, empty ones of a similar size may be inverted over them to keep the crown in a darkened position. This is considered beneficial in assisting in starting them into growth. When close frames are used, similar conditions may be secured by covering the sashes so as to exclude the light. It is important that the soil be placed as lightly as possible about the roots, in order that the heat may pass readily through it. Water of the same temperature should be given often enough to keep the whole well moistened. The very earliest batch of the current year's crowns not unfrequently fails under such hard forcing conditions, hence retarded crowns should be selected. If good crowns are employed after November, and proper attention is given in forcing, each batch of the late ones may generally be relied upon to produce good flowers. Clumps are forced in quantities after Christmas; some of them, if well ripened, may be utilised at any season. In forcing retarded crowns in summer, a temperature of about 65deg is sufficient.

**VARIETY OF RASPBERRY** (William Smith).—We do not comprehend your letter. Is the Raspberry a cross, or what? The fruits were all destroyed on their arrival. We fear it is a useless sort.

**TOBACCO WATER** (C. N.).—Use two gallons to three gallons of water: if hot, the tobacco juice will the sooner be expressed and mingle with the liquid. The aim is to have a distasteful liquid to coat the leaves with, and so prevent the attack of insects. Indeed, there is no need to rigidly measure the water, but by using judgment you may make a safe and sufficiently strong tobacco solution for your purpose without measuring.

**BOOK ON FARMING** ("J.").—Procure Dr. Freaux's "Elements of Agriculture" (John Murray, London, 3s. 6d. net), which we think may suit you. If not, let us know. The newspapers devoted to agriculture are: "North British Agriculturist" (Edinburgh); "Irish Farming World" and the "Farmers' Gazette," both from Dublin; "Farm and Home," the "Agricultural World and Cable," "Profitable Farm and Garden," and "Farm, Field, and Fireside." No doubt there are others specially devoted to agriculture. Do you peruse our own Home Farm page?

**THE "PATTISSON" LAWN BOOTS.**—We desire in this place to bring to notice an improved lawn boot for horses, samples of which have been frequently exhibited. At meetings of the Royal

Fig. 1.

Horticultural Society during last summer, in London. We believe that these boots, from their improvement in strength, adjustability, and comfort to the horse, will be almost solely used, once they become better known. At present they are sold by Mr. H. Pattisson, 55, Killieser Avenue, Streatham Hill, London, S.W. We do not rest in our recommendation of them, on our own opinions alone, but are supported by a large number of leading gardeners, both in and around the metropolis, and the provinces. The boots have also been for three years in use on the Oval cricket pitch, which is of itself sufficient to guarantee their merits. The boot, as shown in fig. 1, is fitted with a strong steel plate turned up at the toe, and having an adjustable screw clamp at the heel, by means of which it is attached very quickly and firmly to the horse's shoe. There is not the slightest pressure on the hoof, and the frog and fetlock are as open to the air as they would be without it, so that the horse works with much greater ease and comfort ("as though he had nothing on his feet,") than is possible with any other boot. The patented "Compactum" Sole is the most durable possible, being made of the best water-proofed English sole leather, in which are embedded (at the points of wear) two or more rubber discs of special quality which add greatly to the durability of the leather, and also render the sole practically non-slipping. It is at the same time kept firm and in shape by the steel plate, and is absolutely prevented from wearing into holes, as happens with all other boots. Fig. 2 is the same boot, but fitted with a leather upper and strap fastening instead of the screw clamp, and is suitable for shod or unshod horses. The toe of the steel plate takes the forward pressure of the hoof, thus saving the front of the boot from wear. It is impossible to have a better boot of this shape. These boots are very durable.

Fig. 2.

**CHRYSANTHEMUM LEAVES BLIGHTED** (A Reader, Cambs.).—The leaves are infested by the Chrysanthemum leaf blight, caused by a fungus named *Cylindrosporium Chrysanthemi*, which is proving very destructive to Chrysanthemums this season. At first small reddish spots appear on the leaves, and these soon increase to large dark blotches, and the leaves turn yellow, ultimately brown or black, shrivel and hang down and lie close to the stem. In consequence of attack, the flower buds do not expand properly, and sometimes not at all. Numerous fruiting pustules are formed on the diseased patches, and produce countless spindle or club-shaped, colourless septate spores, which rupture the epidermis of the leaf, become diffused, and spread the disease rapidly. Spraying with fungicides has not any apparent effect on the fungus, but probably early spraying or dusting with a fungicide would prevent attack. The best course is to remove and burn affected leaves. Probably the wet weather has favoured the fungus, and the hailstorm to which you allude would certainly make matters worse.

**SMALL COLLECTION OF ORCHIDS (S. S.).**—For the sum you name, £15, you may get together an extremely interesting small collection of Orchids, but to do so you should buy a few at a time as occasion offers. To take this amount to a nurseryman and buy at catalogue prices would only result in disappointment, but there are frequent sales in London and other towns of established and newly imported plants, where numbers of healthy Orchids are sold at very low rates. If you cannot attend the sales yourself obtain a catalogue and ask the auctioneer to buy and forward to you any lots you mark if they go at a cheap figure, leaving it in his hands to decide the value, or telling him how high you care to go for certain lots. To mention half the suitable kinds would take far too much space, but a few are flowering species. *Anguloa Clowesi*, the Cradle Orchid. *Cattleya* flowering species. *Anguloa Clowesi*, the Candle Orchid. *Cattleya citrina*, a bright yellow species that should be grown on cork or wood blocks. *Celogyne cristata*, a white-flowering species, most useful for cutting or display upon the plants. *Cymbidiums giganteum*, *eburneum*, and *Lowianum*, handsome plants, whether in or out of flower, and lasting many weeks in full beauty. *Cypripediums* in variety, including *C. insigne*, *C. villosum*, *C. Sedeni*, *C. venustum*, *C. Ashburtoniae*, *C. Leeannum*, *C. Sallieri*, and others. *Epidendrum vitellinum majus*, one of the finest of cool Orchids, with bright scarlet and yellow blossoms; *Lælia anceps* and *L. autumnalis*, *Masdevallias* in variety, four of the best being *M. Harryana*, *M. Veitchi*, *M. Lindeni*, and *M. Tovarensis*, the last-named being the only white-flowering species. *Maxillaria grandiflora*, *Lycaste Skinneri*, one of the best; *Odontoglossum crispum*, *O. Pescatorei*, *O. cirrhosum*, *O. triumphans*, *O. luteo-purpureum*, *O. grande*, *O. Insleayi*, *O. citrosimum*, and *O. Rossi*. These are the cream of the genus. Among *Oncidiums* are *O. concolor*, *O. Marshallianum*, *O. tigrinum*, and *O. flexosum*. *Pilumna fragrans*, *Pleione lagenaria*, and *P. maculata*. *Sophronitis grandiflora* can hardly be left out, and this will be forty of the most beautiful Orchids in cultivation, all easily grown, cheap, and floriferous.

**NAMES OF FRUIT.**—*Correspondents whose queries are unanswered in the present issue are respectfully requested to consult the following number.* (W. P.).—Plum. *Victoria*. (N.).—Apples: 1, *Beauty of Kent*; 2, *Beauty of Bath*; 3, *Duchess' Favourite*; 4, *Ribston Pippin*. (J. F., Kelso).—Plums: 1, *Jefferson*; 2, *Prince Englebert*. Peach, *Sea Eagle*. Nectarine, *Pineapple*.

**NAMES OF PLANTS.**—*Correspondents whose queries are unanswered in the present issue are respectfully requested to consult the following number.* (P. A. T.).—The following are the names of those not named in our last. We received another lot on Tuesday last which you will have the names of in our next. We have had no leisure for naming them: 1, *Thuja occidentalis Wareana*; 2, *Thuja occidentalis*; 3, *Abies pinsapo*; 4, *Cryptomeria elegans*; 5, *Juniperus* var.; 6, *Prumnopitys elegans*. (Stoney Park).—All are British, or varieties of same. Nos. 1 and 6, *Aspidium angulare*; 2, *Aspidium aculeatum cristatum*; 3, *Asplenium Filix-fœmina* var. *cruciatum*; 4, *Asplenium Filix-fœmina* var. *cristatum*; 5, *Polypodium vulgare* var. *cambricum*; 7, *Mentha officinalis variegata*. (Hants)—1, *Cupressus Lawsoniana*; 2, *Pseudotsuga Douglasi*; 3, *Cedrus Deodara*; 4, *Cupressus pisifera* var. *plumosa argentea*; 5, *Taxus baccata* var. *fastigiata aurea*; 6, *Abies nobilis*; 7, *Osmanthus aquifolium* var. *ilicifolius*; 8, *Osmanthus aquifolium* var. *ilicifolius variegatum*; 9, *Escallonia rubra*. (T. W.).—1, *Begonia corallina*; 2, *Begonia purpurea*; 3, *Begonia maculata*; 4, *Codiaeum*, probably *Heathi elegans*; 5, *Maranta zebrina*; 6, *Caladium* sp., stalk wanted.

### Meteorological Observations at Chiswick.

## Live Stock Prospects.

With an abundance of keep in the pastures, and the promise of still greater abundance in the Turnip fields, with full stackyards and fat hayricks, we might readily expect a boom in the live stock trade, but up to the present matters are remarkably slack. A rising of the tide appears to us inevitable, and we may not have long to wait for its commencement. Both beef and mutton are much dearer than they were last autumn, yet store sheep and cattle are still a dragging trade, and once more have we to chronicle disappointment at the autumn ram sales. There can be no doubt that farmers have been hard hit the last three seasons, and they can no longer afford to give fancy prices for sires, especially as wool can only realise 6d. per lb.

That the wool question is the most active cause of the depression is apparent when we see how great is the slump in Lincolns and Leicesters. About five years ago at the chief sales of Lincolns averages of forty or fifty guineas per head were frequently recorded, whilst on two occasions Mr. Dudding had an average of more than eighty guineas. This season the same breeder can only reach about fifteen guineas, whilst those who had been making forty guineas have to be satisfied with eight or nine. Last year hundreds of fine Lincoln rams were sold for three guineas each, or even less, and so far as the sales have progressed the experience is in danger of being repeated. Lincoln mutton is not popular with the best customers, and only a revival in the wool trade can resuscitate the Lincoln.

On the contrary, black-faced sheep are meeting a fair competition. Hampshires, Downs, and Shropshire, though not so dear as ten years ago, are in healthy demand, at prices which should be remunerative. At Mr. East's sale of Hampshire ewes at Hazeldown, 1,049 averaged 60s. 9d. each, and 270 ewe lambs made 44s. 6d. each. At the dispersal of Messrs. Barr's Shropshires, at Odstone, rams averaged £16 13s.; shearling ewes, £4 14s. 2d.; stock ewes, £4 16s. 4d.; and ewe lambs, £2 10s. 4d. At the annual sale of Shropshires at Birmingham, satisfactory prices, ranging up to twenty-seven guineas, were obtained, some of the animals being bought for Germany and Tasmania. For Shropshires, Hampshires, and Oxford Downs there is a much better general demand than there is for the white-faced long wools; by a general demand we mean for the ordinary type as apart from pedigree animals. There is, doubtless, a considerable change taking place in favour of down breeds. In those counties which have been given over almost entirely to the Leicester and Lincoln, cross-breeding is very much on the increase. Not only are farmers importing black-faced rams to mate with long-wool ewes, but numbers of down ewes have been purchased for breeding early lambs. The dam will be also fed off and sold during the ensuing summer. It is gratifying to see farmers getting out of the old ruts. Mutton of the down or cross-bred type defies the competition of imported meat. The great markets are never overdone with it, as they so often are with the over-fat Lincoln and Leicester mutton.

If we do not see a very pronounced rise in sheep as soon as the thrashing machine gets well to work, we need never make another forecast. There are so many things in favour of it. A plethora of fog and aftermath, a fine root crop, plenty of hay, a magnificent plant of young seeds, and small foreign imports. Farmers have been unwilling sellers. When they have money they will buy, and the competition between them and the butchers may bring about something surprising. The fine plant of seeds for next year's pasture must ensure a firm trade for at least twelve months.

The agricultural returns show that we had less sheep last June by 600,000 than we had twelve months before. The number of lambs was about the same, but ewes had diminished by 170,000, and other sheep over one year by 420,000. What is the state of things as regards cattle? The returns show a loss on the year of 208,000, representing a percentage of three. There were 46,000 less breeding cows,

95,000 less cattle over two years (not breeding or milking), 42,000 less yearlings, and 44,000 less calves, under one year. The great diminution in cattle over two years, which represent our home beef supply, is the most striking feature of this report. The percentage is nearly eight, and this shortage in the supply might have had even greater effect on beef prices than has in reality occurred. But it is the future we are dealing with, and it requires little foresight to predict that if farmers are to consume the supplies of roots and forage now in sight, there will be but very small numbers of cattle to spare for the butcher before February or March. Much depends on the autumn corn markets. If farmers are able to realise sufficient money by their sales of grain and Potatoes they will be in a position to keep their diminished flocks and herds off the markets until spring approaches, and in the absence of increased imports from abroad which are far from likely, the British farmer may be for once, if only for a short period, master of the situation. It is almost certain, in our opinion, that meat will be dear this winter; perhaps the prices may approach those which prevailed in 1872-4.

The decrease of 46,000 in the number of cows and heifers is rather a serious matter, for it must have some effect on the supply of milk. If cattle increase all round in price, the rearing of calves will be encouraged, and the supply of milk cows for the town dairies be restricted. As young cattle are relatively dear now, calf-rearing will almost surely increase. In the present state of our herds, especially as regards our breeding stock, it is most desirable that every heifer calf should be reared, and though it might be a little arbitrary, an embargo against the slaughter of all female cattle under three years of age would do more good than harm to British agriculture.

## Work on the Home Farm.

We have had rain almost daily, yet have made fair progress with harvest during the week. The crops are practically all in stook; only a field or two of Rivett's Wheat and late-sown Barley remain standing. The weather has been too unstable to favour Barley stacking, and the fine crops of this cereal are still in the fields. A considerable quantity of Wheat has been led and some Oats. The Wheats have taken more carting than was expected, and the sheaves are heavy enough to warrant the expectation of a good yield. The grain is plump and well fed, strikingly so for such a late season. Barley has got a good deal stained, and there will be few bright samples.

There has been great difficulty in getting men to tie the Barley up after the reapers. Men, who a few years ago left other occupations for a temporary spell of harvesting, but have not been required the last year or two owing to the use of self-binders, have refused with scorn the old prices, and have practically obtained what they liked to ask for on the present occasion. Barley crops are heavy certainly, but 7s. 6d. per acre is a heavy price for tying up and stooking, and that price has been frequently given.

There will be nice pickings for the pigs on the Barley stubbles where Standwell or Goldthorpe has been grown. The ground is strewn with necked ears in some places. Wrench's Prolific, which has become very popular about here, has not suffered in that way, its growth being similar to the old Chevalier. Some of the fields of this kind have been terribly laid, and the grain will be both small and dingy.

As soon as possible we shall put the cultivator through a piece of Wheat stubble, and prepare it for winter tares. After being cultivated, twelve loads of good muck per acre will be ploughed in and the seed sown at once. Ten pecks per acre will be sufficient for immediate sowing. In another month twelve will be required. We drill ours, but some people broadcast by hand. The seed is more easily covered after the drill, and less likely to be robbed by pigeons, which are very fond of it.

As we wrote a month ago, a neighbour was spraying his Potatoes. The work was not well done, and appeared to us very much belated. The results are a striking testimony to the value of spraying, as far as present appearances go. The uneven and patchy way in which the work was done has provided a splendid test. The most unobtrusive person could not help remarking the extraordinary difference between dead, or dying, and vigorously growing haulm on closely adjacent patches. In other places the gradual change in appearance is ample evidence of the slow clogging up of the strawsoniser, and a sudden change once more to healthy growing conditions shows the place where the machine was stopped and put into effective order. Such an absolutely conclusive test could hardly have been organised with intention and carried out so well. This was done on August 15, which would be considered very late for spraying. The machine was a new one, and sent by Messrs. Strawson on approval. There should be a sale.

## BARRS' GOLD MEDAL DAFFODILS

Have received Twelve Highest Awards, 1902, including **TWO GOLD MEDALS**  
Descriptive Catalogue of all the finest sorts in cultivation free.

## BARRS' GOLD MEDAL TULIPS

Have received **FIVE GOLD MEDALS** from the Royal National Tulip Society; **SILVER CUPS** at the Great Temple Flower Shows, 1900 and 1901, and **GOLD MEDAL** 1902.

## Decorations of Autumnal Leaves.

**B**ELIEVING that information or suggestions on such a subject as the above will be useful at this season, "the afternoon of the year," we print the following from an American contemporary:—"Since an observant American woman has taught the Parisian belles how becoming our

autumn leaves are to dark-haired ladies, and thus created a demand for this foliage as a personal decoration, its wonderfully varied tintings have been more generally noticed and admired; and many attempts are made to retain this beauty, which, when properly preserved and managed, gives elegance to the humblest apartment.

"Though a few trees may ripen their leaves in August, it is not till the middle or last of September that we can obtain them in variety; while even as late as November we must wait for some species. Then, whether we pick them from the ground or cut twigs and branches from the trees, only the most perfect in form, and the clearest in their hues, and the most nicely shaded should be selected, being careful that each leaf has its stem uninjured.

"As soon as possible after gathering them the leaves must be pressed. If they begin to wilt or shrivel before you are ready to press them, put them in water, and keep them there till they revive. See that no soil, no foreign substance of any kind, is on either side, and then with a warm, not hot, flat iron press and iron each leaf on its upper surface till it is perfectly dry; spreading it for this purpose on several layers of paper, or on an ordinary ironing-board, just as if it were cotton cloth. This over, oil each leaf on the same side on which it was ironed with linseed, olive, or lard oil, using a small camel-hair brush, or a bit of

**R**EADERS are requested to send notices of Gardening Appointments or Notes of Horticultural Interest, intimations of Meetings, Queries, and all Articles for Publication, officially to "THE EDITOR," at 12, Mitre Court Chambers, Fleet Street, London, E.C., and to no other person and to no other address.

cotton batting tied to a stick, and then place them on dishes in the sunshine to dry. When dry, reject all those that have a semi-transparent or oily appearance; to prevent this, get the thickest leaves you can for your collection, and do not oil them too generously nor with a rough brush.

"If you wish to arrange the leaves in boughs, or sprays, or long garlands, procure a few knots of brown worsted, and a quantity of fine wire; old bonnet-wire cleared of its covering, or the wire from the heading of old brooms, is of the right size, and very convenient to use. When the oiled leaves are dry, assort the different kinds according to their species—that is, place the Rock or Sugar Maples together, then the Red or Swamp Maples, the English Elms, the American Elms, the White Oak, the Black Oak, and so on; because, though several species are allowable in a garland, it would be unnatural to mingle them in sprays or boughs. The only proper way, however, of bringing them together is to bind the various sprays into a large bouquet; thus the contrasting forms and hues have a good effect.

"Cut the wire into pieces of different lengths. You will need a great many 3in or 4in long, several a foot long, and a few 2ft or more, according to the length of the branch or the garland you wish to make. Take the smallest leaves for the tips of the sprays and branches, and follow these with others of larger size, proceeding regularly till you have the largest leaves at the base of the branch; keeping an eye, at the same time, to the agreeable union of varying shades, and studying the marking and blotching of each leaf, so that it shall have no glaring contrast in its nearest fellows; and thus, with the greatest variety in the group, the whole are blended harmoniously and pleasantly.

"Begin your work by attaching all but the very smallest leaves to the short wires, placing the wire beneath the stem, and in such a manner that it strengthens its whole length; and then wind the worsted around both so closely and tightly that nothing of the stem or wire can be seen. Then take a small leaf and fasten it in the same way to a long wire, which is to be the main stalk of the branch. Along this dispose the other leaves naturally; bending the ends of their wires as needed, and covering all together by continuing to wind the worsted as before. Several branchlets or sprays may thus be gathered on one stalk, forming a large bough or a long garland. Avoid stiffness and flatness of position; set and bend the stems in a life-like manner. For this the wire stems are a great advantage. They also contribute to the durability of the leaves, which, if preserved with no support save their own stems, are soon broken unless extreme care is taken.

"The beauty of Oak leaves is much enhanced if clusters of acorns in their cups are introduced among them. The cups must be punctured with an awl, to admit the end of the wire that is to serve as a stem, and the acorns then glued to the inside of the cups. When these are dry, wind the wire with the brown worsted as in uniting the leaves. Birch burrs must be glued directly to the wire, which it will be convenient to wind with the worsted, and form into a branch before the glueing takes place. They are a pretty addition to branches of the golden Birch leaves.

"These boughs and garlands, arranged tastefully in vases, drooping around pictures or statuary, or hanging upon the walls of a room, seem to lend it the sunshine of a perpetual Indian summer. The most desirable leaves for this purpose are those of the Oak, Maple, Elm, Sumach, Birch, and wild Cherry; though contributions from woody shrubs and garden bushes never come amiss, if of substantial texture and smooth surface; and green leaves of Ferns—fronds of the common Brake—with their long plumes of verdure, make an agreeable contrast to more brilliant colours and more fanciful shapes. Fern leaves should be ironed in the same manner as other foliage; but they need no oiling, and if not hung where the air is intensely hot and dry, will remain handsome several months.

"It is a mistaken notion that autumn leaves need varnishing. Varnish makes them brittle, and more liable to crack; while the excessive lustre that it imparts is unnatural. Oiling gives sufficient polish, deepens, clears, and preserves the colours, and keeps the tissues somewhat elastic. When the leaves get dusty wipe them with a damp cloth. If they curl, damp them, and place the branch for a few hours between papers under a pile of heavy books.

"The changed leaves of autumn may also be used for other ornamental purposes. Small wreaths to surround unframed pictures can be made, fastening the wired stems by sewing, or by winding with worsted, to a narrow circle of pasteboard, or a ring of wire-taste; the Sumach, Elm, or Cherry leaves are best for these. And carving may be successfully imitated with Oak leaves and acorns. For this, glue the under surface of the leaves to a picture frame of pasteboard, or of wood stained a dark colour; cut the acorns, and their cups also, in halves, and intersperse them among the leaves, glueing them in a flat position, and then varnish the whole. The same work makes a pretty front for a bracket. And little sprigs and branches of Maple, Elm, or Cherry, with their natural stems, may be ironed, and then fastened with gum tragacanth to the pretty white-wooded boxes, letter cases, and other articles that are prepared for painting and decalcomanie; being afterwards lightly varnished, or not at all, according to fancy. Sprays of Maple or Elm, or Oak leaves and acorns, may, in the same way, ornament pasteboard or wooden slips for letter and card racks; the lining which should be of the same shade as the leaves, being first glued to the frame."

## A Discourse on Wasps.

The monthly meeting of the Shirley (Southampton) Gardeners' Association was held in the Parish Room, on September 22, when Mr. B. Ladhams presided over a good attendance of members. The evening was an open one for discussion, which was started by the hon. secretary, Mr. J. Miles, who exhibited three wasps' nests; one built in a bellglass on the top of a bee hive, another taken from the ground and placed under a glass, and a third nest destroyed by cyanide of potassium. The former two had the wasps alive within them.

He remarked that the injuries to fruit and loss to fruit growers and gardeners by the depredations of these insects upon the ripe or ripening crops were to a greater or less extent a yearly trouble. In the year 1893, the visitation was so great that it was known as the "wasp plague." The crop of Gooseberries was completely cleared when approaching ripeness; quite two-thirds of the Pears were damaged and destroyed; Apples about one-third; and Plums about half. In another locality, Grapes in houses and outside suffered severely; all the Peaches were eaten before they were ripe, and many of the best Apples and Pears eaten out, leaving only their skins. The wasps' nests, besides being much more numerous in 1893 than in other years, were noticed in some instances as being of a greater size and more fully tenanted. One man destroyed 180 nests on 600 acres of land; 200 nests were taken in one nursery; 300 on 300 acres; and in one instance, where a bonus of 6d. per nest was given, 470 were taken within a half a mile radius of a kitchen garden which was the centre of operations. Other returns gave 20 nests ploughed up in a field, 36 taken in a radius of a quarter of a mile, and 23 nests within 96yds of a certain stone wall.

Considering the utility of the wasp, Mr. Miles said evidence showed, unquestionably, that the injuries far exceeded the benefits of its presence. In Great Britain we have seven species of social wasps, that is, of wasps living together in societies formed of males, females, and neuters, commonly known (as with bees) as drones, queens, and workers. These seven kinds are divided into two sections of (1) ground, and (2) tree wasps, according to where their nest is formed, in a hollow in the ground, or suspended in the air from a bough.

The colonies for the year are begun by the queen. At first she has to carry on all the work, to build the nest, to lay the eggs, and feed the larvæ. The wasp remains in the egg condition eight days; the larvæ thirteen, and the pupæ about ten. These are all workers, which take up the duties begun by their queen in building their home. Towards autumn a great change takes place in the nest. Only males and females are produced, and shortly afterwards the wasp colony as a social establishment comes to an end.

The males having fulfilled their allotted part by pairing with the females, die; so also do the workers. The nest decays, and all that remain of the summer colonies and their quarters are the females, which will leave the nest and hibernate in their selected shelters until spring comes round again, thus completing the year's cycle of wasp life.

One of the best things to destroy the nest and wasp is cyanide of potassium, which can be used at any time, morning, noon, or night. This being a very violent poison, Mr. Miles did not advise the use of it except in absolutely trustworthy hands. To relieve the pain of a wasp sting, ammonia, soda, chloroform, ipecacuanha, and onion juice were good remedies.—M.

### Cypripedium × Mrs. F. Hardy.

This beautiful hybrid was first exhibited from St. Albans in 1895 when it was honoured by the Orchid Committee of the Royal Horticultural Society. It was obtained as a cross between *C. superbiens* and *C. bellatulum*, and traces of both parents are readily observable. The stout petals are very distinctive, with purplish spots on an almost pure white ground. The lip is somewhat small, and is of a creamy white (very pleasing) flushed with rose, darkening towards the mouth. The large dorsal sepal is white, faintly tinged with green, and bears rows of dark maroon spots. It is a rare and beautiful hybrid.

### Dendrobiums: Their Growth and Culture.

(Continued from page 283.)

*D. chrysanthum* again is quite distinct from all others in appearance, and in cultural requirements. It commences to grow soon after the flowers are past, and is usually growing all through the winter. It is a very restless plant in fact, and should never be really dried at the roots. The flowers occur on the newly formed growths often before the leaves fall; they are deep golden yellow in colour, and with a delicious fragrance during the fortnight or so they last. Basket treatment is best for it, so that the stems may take their natural pendant direction, and the heat of the intermediate house is quite enough for it.

*D. chrysotoxum* is of the evergreen section, its flowers produced in side racemes from the bulbs, and brilliant yellow in colour. The variety *sua-vissimum*, which is often described as a distinct species I consider superior to the type; it is certainly brighter, the bright yellow segment being well shown up by the deep maroon blotches on the lips.

*D. crassinode* is one of the very finest of the deciduous sorts, and a showy and beautiful Orchid. Its thickened nodes on the stems render it easily recognisable, whether in or out of flower. The blossoms occur almost over the whole length of the stems, and are white, the sepals and petals heavily tipped with rosy purple, the lips having a large yellow area at the disc, and tipped like the outer segments. The only fault with this superb species is an inclination to go off at the base of the stems, a fault that is made worse by overwatering in the early stages. It is a native of large tracts of country about Moulmein, and is fortunately always cheap and plentiful. The principal variations from the type are the albino form and the highly coloured *Barberianum*, the latter being rare, though scores of plants are sent out under this name.

*D. dallhouseianum* is a strong vigorous growing species, often considerably over a yard in height, bearing large pale yellow blossoms with blotches of purple on the lip. Plenty of room is necessary to grow this superb plant, which is a native of Burmah, introduced in 1837. *D. Dearei* is one of the most free-flowering species in the genus, producing in great quantity its beautiful pure white blossoms, and lasting in full beauty for many weeks.

To grow it well very abundant atmospheric moisture is needed and strong heat, the plant being a native of the island of Mindanao, in the Philippines. *D. densiflorum* is a bright golden yellow flowered evergreen species of easy culture, and almost indispensable in collections.

*D. Devonianum* is one of the best of the deciduous group, having long pendant stems that in their season are wreathed from end to end with the bright showy blossoms. The sepals and petals are like those of *D. crassinode*, the lip being covered with short hairs and prettily fringed. *D. Draconis* belongs to the nigro-hirsute section, and has large ivory white flowers tinted on the lip with orange. It flowers in summer, and is also known as *D. eburneum*.

*D. Falconeri* is a very distinct plant in habit, consisting of a large number of short stems from which other stems start, making quite a dense mass of growth. The flowers are very lovely, a pure white tinged in places with rose, the petals tipped with bright amethyst purple, the lip having a rich orange blotch in the centre. It is not everywhere a success under cultivation, but usually holds out fairly well if grown in a strong and very moist heat, and induced to rest afterwards by keeping it cool and dryish at the roots. The syringe should be fairly plied about the growths in summer to keep thrips in check, these being its worst insect enemy. Shrivelling for lack of sufficient moisture in winter must never be permitted.—H. R. R.

(To be concluded.)

Cypripedium × Mrs. F. Hardy.

### The Week's Cultural Notes

There is no such thing in Orchid growing as perfect immunity from insect pests, and the most careful grower with the healthiest plant must ever be on the alert. Just now is perhaps the most suitable time of the year for a thorough look through of the plants in the Cattleya house. A good deal of the new growth is complete and getting hardened, and if there are any insects present on the plants it is this young and valuable growth that will be attacked by them during the ensuing winter. The stages, glass, and walls of the house, too, may now be cleaned with advantage, and it will be found most convenient to do this first and bring the plants back to a clean house.

A careless look at the plants to see if any insects are there is not sufficient. Every part of them must be carefully gone over, taking especial pains with the woody rhizomes and the scales about the base of the bulbs. Here scale insects of different varieties find a congenial home, and are most difficult to eradicate. First of all immerse the plants in a tub or large pail of soft tepid water, having meanwhile prepared another vessel of water with a solution of soft soap and tobacco water. When the plants have dried slightly

from the clean water dip the heads in the soapy solution, but avoid wetting the compost with this more than can be helped. They should not be stood upright after this, or the soapy water will run down into the roots, and it is very apt to cause fungoid growth there.

Lay them on their sides then to partly dry, and then with a sponge go over them leaf by leaf and stem until they are thoroughly cleansed. A bit of pointed stick should be used, to remove the insects from all parts that cannot be reached by the sponge, such for instance as the leaf axils and the under sides of the rhizome. Both the sponge and the stick are apt to puncture the leaf unless care is exercised, and although this work seems very simple, it must on no account be left to careless and inexperienced assistants, or great mischief will be done.

It is not always that a spare house is at command to put the

plants in while the house is being cleansed, but in this case the plants can, as a rule, be placed on one side while cleaning operations go on at the other. Hot lime may be brushed on the walls after these and the glass and stages have been cleaned, the lime being distasteful to insects and killing the spores of moss that usually thrive in the damp of an Orchid house. Brush it well into all the corners, both above and below the stages, and clear the latter of all rubbish and dust.—H. R. R.

#### Rare Orchids at Aberdeen.

Two very pretty Orchids were recently to be seen in Messrs. Reid and Co.'s shop window at 145, Union Street, one *Cœlogyne Dayana grande*, which is one of the rare varieties of this genus. When first flowered and exhibited by Baron Schröder in London it created some interest among Orchid growers and others interested in Orchid culture. The present plant, we believe, was a small piece imported about seven years ago, and bought at an Orchid sale in Edinburgh by Sir William Henderson, LL.D., of Devanha. Since then it has increased rapidly and now carries over 500 blooms. This plant is known as the Nicholas Orchid, and is a native of Borneo. The other variety, *Saccolabium Blumei majus*, is a very fine Orchid, a native of the Indian Islands. Mr. John Proctor, gardener at Devanha House, is to be complimented on his success in Orchid culture. "We do not think," says the "Aberdeen Free Press," "that any of these varieties have been seen in such perfect bloom in the North of Scotland before."

### Arbor Days.

If the opinion of Herr Reichert, of Berlin, is correct, that Great Britain is almost at the bottom of the return giving the proportion of forest land to the total area, viz., 11,272 square kilometres, I think it is time that public interest should be aroused in the matter of forest-tree planting. The return alluded to gives to Russia and Sweden forests equal to 42 per cent. of their area, to Austria 31, to Germany 26, to Norway and India 25, to France 16, to Portugal 5, to Great Britain and Ireland 4, and to Cape Colony 0.29. Parts of Siberia, South America, and Central Africa remain the chief sources of supply for the near future.

In France the alarm was given not long ago by M. Melard, and M. Guinier, an inspector of forests, believes that the planting of forests in France is now full of promise. England wants to save Egypt from ruin, perhaps never to leave it again; but what says another inspector of forests, M. Roger Ducamp? "If the pax Britannica in Egypt means the drying up of the Nile, such a peace is worse than anarchy"; and Lord Rosebery once said, "The Nile is Egypt, and Egypt is the Nile," whose sources are constantly decreasing in consequence of the destruction of the forests there. Without forests, little water; without water, no crops, no cattle, and rent and taxes cannot be paid.

Of course Great Britain has an insular and a moist climate (exactly what is wanted for forests), and has coal possibly sufficient for centuries, and therefore does not require firewood; but it is quite different when we have to deal with the question of timber, of which from 12 to 14 cubic feet a head are annually used, although iron is more and more taking its place in ships and house-building. Yet Dr. W. Idelich, a forest expert, in an address delivered before the Society of Arts, predicted in spite of this a positive timber famine in the near future, and concluded by saying, "That country that first engages in systematic timber cultivation on a large scale will do much to assure its own perpetuity as a nation," and, in my opinion, as a wealthy nation also. Take Palestine and Spain as instances of the gradual simultaneous decline of forests and prosperity.

Take the King of Greece and Princess Sophia, on the other hand, who on their own estates and at their own expense are planting forests, so convinced are they that the gradual deforesting of the kingdom is leading to disaster. The ratio of timber consumption in Europe is constantly increasing. It is said that Germany needs 30 cubic feet a head, and that the natural growth cannot keep pace with the demand, especially for soft woods, is shown by the news that the limit of production has been reached in Scandinavia, and that they are now awakening to the fact in Sweden, so that the school children planted last year on Arbor Day no fewer than 600,000 trees.

Canada can still export, although many districts are already depleted; but the United States—where private owners are now largely planting (and Nebraska has now a billion of forest trees growing on land which in former geographies was noted as the "Great American Desert" from their total absence)—have against this an annual consumption of 350 cubic feet a head, or 25,000,000,000 cubic feet, for fuel and lumber. The United States now use the annual growth of 1,200 million acres of woodland, whereas the total forest area is less than 500,000,000 acres, so that more than half of the annual consumption is a draft upon forest capital. Without regarding street or suburban traffic, 90,000,000 railway sleepers are annually required for renewals at 25 per cent. advance on the price of ten years ago, and 600,000 telegraph poles at 50 per cent. advance.

Mr. N. A. Eggleston, of the United States Department of Agriculture actually states, "Lumber alone would load a train of cars sufficient to encircle the earth at the Equator, and, if we add all other timber, posts and fuel, such a train would be 100,000 miles in length; or it would require 480,000 ships of 1,000 tons each to load the forest products." According to his calculations the commercial value of the forest trees of the United States is so great that it exceeds that from any other source. In 1894 the value of the cereal crops was £208,601,589, whilst that of the products of the forests for that year was £3,000,000 in excess; the value of the gold and silver raised was only one-fifteenth, and the whole value of all mineral products was only about one-half of the forest products. Such official statements are bound to arouse public attention!

Great Britain was well provided by Nature with great forests. The Druids had their fine groves of Oaks, and Queen Elizabeth was amongst the first English-speaking advocates of forestry. Comparatively few of these Oaks remain; but according to the best authorities they may live 1,500 years—only Cedar, Sequoia, and Baobab having a still longer life, while Poplars reach only 50, Elms 335, Maples 516, Birches 576, Oranges 620, Cypresses, Walnuts, and Olives 800, Planes 1,000, and Limes 1,100 years. Had former generations no duty to posterity? They had only a life estate in the forests, with no permission to waste; and as far as possible the present generation should try to rectify this great injury to the British commonwealth by planting largely. New Zealand has done this; and South Australia, at least for some time, paid a bonus for successful plantations of forest trees, and distributed them free of charge.

Cannot wealthy Great Britain follow the example of Germany in raising forest trees at cost price for municipalities, and paying a bonus of ten shillings an acre for forests planted by them, or (with some restrictions) to private persons who will do the same? There are, in fact, townships in Germany where they require no district taxation. At Freudenstadt, for instance, they have been since 1875 in the enviable position of being able to pay to each of about 1,300 burghers a sum varying from 25s. to 55s. from the profits of the forest owned by the little town. Another instance is Saaldorf, where the eighty-four ratepayers each receive every year wood and turf for burning to the value of £5, and lately the sum of £830 was divided amongst them, or nearly £10 to each, as surplus from sales of timber. This village had yet a further sum of £3,000 in hand, and, of course, no debts.

The initiation of such a system by the Government seems to me a *sine qua non* for success, at least with the smaller landholders. Even so long ago as April, 1863, the Secretary of State for India wrote to the Governor of Madras: "To forests, from their nature, the usual maxim of political economy, which leaves such undertakings to private enterprise, cannot be applied. Their vast extent, the long time that a tree takes to reach maturity, and the consequence that few persons live long enough to obtain any, and more especially the highest, returns for expenditure, even once in the course of their lives, are proofs of the necessity that forest management should be conducted on permanent principles, and not left to the negligence, avarice, or caprice of individuals, and therefore point to the State as the proper administrator, bound to take care that, in supplying the wants of the present generation, there is no reckless waste, no needless forestalling of the supply of future generations. This is matter of experience, not in India only, but in all parts of the world."—F. E. H. W. KRICHAUFF (in the "Journal of the Royal Horticultural Society.")

(To be concluded.)

#### An Early-Flowering Chrysanthemum Show.

At Bolehall House Gardens, Tamworth, on Saturday last, when a number of growers met at a friendly meeting on the invitation of Mr. W. Sydenham, cups for the following four classes were offered:—Twelve bunches early-flowering decorative Chrysanthemums, distinct; twelve bunches early-flowering Pompon Chrysanthemums, distinct; six bunches early-flowering decorative Chrysanthemums, distinct, catalogued in 1900 or since; six bunches (three yellows and three whites) distinct early-flowering decorative Chrysanthemums. All had to be grown by the exhibitor in the open, and not disbudded. An exhibitors' lunch was given at one o'clock. Mr. W. Sydenham's own Chrysanthemums, at least 3,000 plants, were available in their beds, to show habit, &c., and for reference in case of need.

#### October Flowering Chrysanthemums.

When frosts come and despoil the beauty of flowers in the open, and there is generally a scarcity of flowers in the majority of gardens, unless a speciality is made of growing in pots a good batch of Chrysanthemums which bloom somewhat early. There are now in commerce some splendid varieties for the purpose, which if grown well will give fine results. Some which I shall include in my list may, by taking the early kinds, be flowered throughout September, but all can be so managed as to bloom in October. Comtesse Foucher de Cariel (orange bronze), one of the best of that colour; Goacher's Crimson (light crimson), a great acquisition. Mdle. Marie Masse (lilac mauve).

Market White.—Few Chrysanthemums are finer, and it has proved a grand variety for flowering from the middle of September till the middle of October; the flowers are perfectly white, and are fuller than those of Madame Desgrange. The only objection I have to it is that when cut the blooms seem to fade quickly. This, however, may be because the wood is extra hard, as I have found that when the stems are cut to the soft wood the flowers last better. Matters may, however, be improved in this direction by feeding the plants liberally, as the value of Chrysanthemums often lies in the fact that they can be cut with long stems. Perhaps others will give their experience of this variety.

Parisiana.—I have this season seen a few flowers of this new introduction, and I have formed a very high opinion of it. Those who have opportunities of keeping thoroughly up-to-date should certainly try it. Ryecroft Glory, well known yet still indispensable. Sadi-Tahih-Bey (pink), good for cutting. O. J. Quintus and its white sport are good varieties to grow in quantity, so also is Lady Selborne and Yellow Lady Selborne. Mytchett Beauty is a grand yellow with stiff stems, fine for supplying pot plants or for cutting. Albert Galy (terra cotta) is one of the most pleasing of its class.—H. D.

#### A Time for Watchfulness.

A season when great watchfulness is needed has now arrived, as much damage is frequently done to unprotected plants in the open air, when sharp frosts occur during the last week in September. Some cultivators take it for granted that Chrysanthemum and similar plants are safe in the open air until the first or second week in October. In our treacherous climate it is not wise to entertain this belief, but to be prepared for emergencies not later than the present time. During ordinary seasons no harm may be done, but ever and anon those caught napping receive a severe lesson, as was the case some years ago, when thousands of Chrysanthemums in pots were utterly ruined.

In some private gardens, where the Chrysanthemum quarters are surrounded by walls or buildings, or partially protected in a similar way, the plants escape when those grown in open positions in the same garden are ruined unless protected. Position, therefore, needs to be taken into consideration. It seems quite probable that sharp frosts may occur suddenly this year, as the temperature of the ground is already unduly cold, owing to the wet, sunless season, and I have often noticed that after such seasons real autumn weather comes very suddenly. I do not advise gardeners to rush their plants under cover at once, because I know full well the advantage of leaving them in the open air as long as possible provided the buds have not begun to burst, as the practice not only tends to prolong the display, but also to keep the plants sturdy, and the flower stems stiff.

When, however, the buds are swelling, a slight amount of frost injures them and prevents the petals from unfolding satisfactorily, even if the buds continue to swell. Such plants should be placed under glass at once, or be protected at night by canvas

or other suitable material. As far as possible houses should be got in readiness, so that when danger threatens many plants can be housed quickly. We always get some warning. I have never known Chrysanthemums badly injured by an isolated night's frost. When, however, we get five or six degrees in one night it is necessary "to look out," as the following one may prove ruinous.

Good measures to take at such times are the following:—Place under glass, temporarily, in a building all plants well advanced. Others, which must be left in the open air, should be removed to sheltered position, where, if possible, some kind of framework can be placed over them, and covered with mats or canvas. Even this cannot always be done where there are hundreds of plants to be dealt with. A good plan, then, is to get a heap of dry straw or bracken in readiness under cover and watch the weather closely. If at any time during the evening there is the slightest doubt as to whether or not the frost will be severe enough to injure the plants, be on the safe side, turn the pots down on their sides, and cover pot and growth with the material in readiness.

The shoots of Chrysanthemums are this year far from ripe, and special attention will be needed to prevent injury by frost. The above are measures which I have often successfully adopted, and by doing so have saved hundreds of valuable plants, when many others in the same district have been ruined. That is why I have penned this note, as I think it is not always the man who writes in the most fluent style who does the most good, but rather he who hits the right nail on the head at the right time. The motto from the present time onward should be watchfulness.—CHRYSANTHEMUM GROWER.

## The Fern Mite.

In the Journal for September 4, under the heading "The Destruction of Unhealthy Plants," readers are asked to give their experience with certain pests infesting Ferns, i.e., *Macrobiotus Hufelandi* and *Oribata demersa*. From lack of knowledge as to the identity of the pests named, I do not know whether I am right in assuming either of them to be identical with a very small pest we call "Fern mite," and one which has been most destructive in many establishments at Edmonton in North London, during the past year or so, particularly among the general market species and varieties of *Pteris*. The first indication of their presence is a rusty and disfigured appearance of the young fronds, as they are throwing up, and in a comparatively short time—only a few days in many cases—the plants present such a crippled and unsightly appearance that they are absolutely of no use for the purpose they are grown.

At first we were at a loss to account for this unnatural appearance of the plants, and as your correspondent suggests, the man in charge was suspected of being neglectful and careless in his watering, but afterwards, when whole batches of plants were thus affected, we found them—on examination with a pocket lens—to be infested with a small mite similar to red spider, though much smaller; and more recently, with the aid of a small microscope, I have been able to examine them more closely. With but a limited knowledge of the subject and the life history of the pest, I cannot offer an opinion as to its exact identity, but should be pleased if your correspondent could give us a fuller account of his observations and experience, and also if he can suggest any preventive measures or efficacious remedy whereby they can be destroyed without injury to the plants.

My own experience so far, is that the furnace is the best place to destroy them so soon as their presence is detected. When one has several thousand plants thus affected, it means, however, a serious loss to dispose of them in such a manner, especially after growing them for seven or eight months, and in a few weeks expecting to get sixpence each for them. I may say that we have tried dipping the plants and syringing them with many insecticides and concoctions, all with very little effect, and have also placed individual mites in a small cavity on a piece of glass into which a drop of the various solutions has been placed, and watched them through the microscope struggling to free themselves, and eventually crawl away little worse for the bath.

Aridity of the atmosphere is said to be the cause of their appearance, but I have syringed and damped the plants overhead daily, maintaining the atmosphere almost at saturation point continuously from the time of potting up, without any appreciable effect upon the "mite," and I know, sir, there are many growers besides myself who will feel very grateful for any hints that expert or scientific opinion can give, that will enable us to combat successfully with this pest, and thus confer that benefit upon employer and cultivator which Mr. Ollerhead so aptly concludes would result in public good. What a vast field for knowledge and research in this direction there is for the cultivator of plants; but, alas! £1 a week is hardly likely to induce or permit of an investment in microscope, nor many microscopic works.—TREM.

### Hybrid Perpetual Roses.

The rather cold and wet season has been favourable to the growth and flowering of Hybrid Perpetual Roses in the north of England. In this garden they have not flowered so freely, or produced such fine blooms, for several years. The same result has been noticed in other gardens, and two large growers recently informed me that their H.P.'s had done splendidly, but just the reverse with the Tea Roses. The flowering season has been quite a fortnight later than it usually is. The weather at that time being cool, with not much sun or rain, the blooms remained a long time in good condition, keeping the colours so well.

Strange to say, that while so many fruit and other trees have been so badly infested with aphides and other pest, our Roses have not been so clean for a long time. They are in rather a sheltered position, and this may have had something to do with it. Spraying with quassia extract periodically will generally keep them clean, but this season only one application has been found necessary, early in the season. The maggot, too, which so sadly disfigures the "Queen of Flowers" very often, has not been so prevalent this season. The bulk of our Hybrid Perpetuals are arranged on a border one hundred yards long. They are planted in groups, one variety only in each group. By this method of planting the characters of each variety may be better noticed, as well as the colour and form of the flowers.

Nearly all Roses in this section have done well. I should like, however, to mention a few varieties that have been particularly good. Mrs. John Laing, which is always good, has excelled itself, producing some really beautiful blooms of fine form. Amongst Hybrid Perpetuals this is my favourite Rose, which is the reason of it coming first in the list. Writing recently in the Journal on Roses for cutting, "H. D." puts this Rose first on his list, so perhaps he may consider it the best for that purpose. In Messrs. B. R. Cant and Sons' catalogue is the following description: "Soft pink colour, very large and fine form, a good grower and abundant bloomer, quite one of the very best varieties for all purposes, and cannot be too highly recommended."

Violet Bouyer is a Rose that I have not had a very good opinion of until this year. There is not much substance in the blooms, and they are so much affected by the weather. This year it has given some very chaste blooms of good shape. The strong growing Margaret Dickson has kept up its reputation by producing fine blooms. This Rose, like the Marchioness of Londonderry, is somewhat formal in its growth. The latter, by the way, does not do very well here, it makes good growth, but nearly all the buds are deformed.

Another white variety that must not be omitted is Merveille de Lyon, which has given very large blooms of good form. Suzanne Marie Rodocanachi, a Rose always worth growing, if only for its very distinct colour, rosy cerise, has done better than usually, although it is always a beautiful Rose, and is very pretty in the bud stages.

Général Jacqueminot one of our oldest Roses, but still a general favourite on account of its bright colour and fragrance. This Rose always blooms well, but this year has produced large masses of flowers, weighing the growths down to the ground. In Ulrich Brunner we have a Rose perhaps nearly as well known as the "Général." The blooms are of quite a different type; the growth, which is always strong and clean, are stronger than usual; but there has not been such a marked difference in the blooming as there has been with many other varieties. These two Roses are amongst the most consistent varieties, nearly always doing well.

Louise van Houtte, a very dark coloured Rose, which does not do very well here, has both grown better and given some fine large blooms of beautiful form. Indeed it has done better this year than I ever remember seeing it before. The same may be said of François Michelon, which has flowered profusely, some of the blooms being very large and double,

and beautiful shape. Alfred Colomb should have been included with Général Jacqueminot and Ulrich Brunner for its consistent character. A strong grower, free blooming, and never hardly failing, but is better than usual this year.

In Pride of Waltham we have a Rose with a distinct colour, rather a bright flesh colour. Its habit is very like Suzanne Marie Rodocanachi, and, like this Rose, is very pretty in the bud. The blooms this year have been deeper coloured than they usually are, owing perhaps to the dull weather experienced at the time they were in bloom. Fisher Holmes is a good Rose for massing. It produced a large quantity of flowers, but it is not of a very pleasing colour, and the blooms are rather wanting in substance. Etienne Levet has done much better here this year than it usually does. Marie Baumann, a Rose of beautiful form, is rather difficult to grow well; but has flowered well this season, some of the blooms being almost perfect. A weak point in this Rose is its slender stems, so that the blooms hang down, and cannot be seen to the best advantage.

I should like to include two other varieties, both rather old ones. Charles Lefebvre, too well known to need any description; not one of the best of growers, but the blooms have been especially good this year. The same may be said of the Duke of Edinburgh, another well-known Rose. It may be as well to say that the Roses are allowed to grow naturally, and very little, if any, disbudding is practised. —J. S. U.

### The Farquhar Rose.

This Rose is a perfect rose colour, but at the Rose Conference period it was this innocent subject which somehow or other gave rise to the story of a blue Rose. Our contemporary, "American Gardening," publishes what it terms "the real facts of the case," and ends by saying: "We commend this information to our English horticultural friends." If the writer of that note in "American Gardening" will turn to our issue for July 3, he will there find "the real facts of the case" in print, nearly two months before they appeared in our transatlantic contemporary.

### The Eternal Crimson Rambler.

"Can you recommend me a good climbing crimson Rose?—now I don't want Crimson Rambler." How many times I have been thus confronted at the shows during the past season, I would not like to say. Failure with this beautiful Japanese Rose is not confined to one district. Two of the chief causes of failure are planting against a wall, or in a confined place, both of which this giant resists. But we want Rambler Roses on walls, and sometimes in confined places too. Now, in "Rubin," a new competitor of the Rambler type, we have a good Rose. It is a good, vigorous grower, not subject to red spider, with deep green foliage and somewhat larger flowers than Crimson Rambler, produced in looser panicles. I have no hesitation in advising those who cannot grow Crimson Rambler to try Rubin, and to those who do grow Crimson Rambler—well, try Rubin also.—E. J. LOVE.

### New Roses from Waltham.

Among the new varieties of Roses sent out by Messrs. William Paul and Son, of Waltham Cross, Herts, are the following:—

Waltham Rambler, a hardy and robust climber, having large panicles of rosy-pink single flowers. It resembles Leuchtstern, but differs in having a much more vigorous habit.

Corallina, now becoming quite well known, though only seen for the first time in 1899. The flowers are deep rosy crimson, shaded with coral-red. It is specially good in the bud state. It is a very distinct variety, a good autumnal, and handsome for massed effect in beds.

Sulphurea is an excellent new yellow bedder, of vigorous growth, and has glossy dark foliage, so that mildew never settles upon either leaves or stem. The crimson-brown shoots contrast beautifully with the profusely borne sulphur-yellow flowers. It is quite hardy, and a fine yellow bedding or massing Rose, and is said to be very fine for pot culture and forcing. An Award of Merit was accorded by the Royal Horticultural Society to it, on September 23. We are indebted to the raisers, Messrs. W. Paul and Son, for the use of the illustration.

Each of the foregoing are novelties of last year or the year previous, but amongst the new bedding and decorative Tea Roses for 1902, there are Chameleon, whose rosy flesh-coloured blooms were quite an attraction on Messrs. W. Paul and Son's stand at the latest Drill Hall meeting. Fairy Queen, with fawn hued blossoms, we have occasionally noted during the past season; and reference has also been made to the new Salmonea and Morning Glow, the former having flowers of a bright rosy crimson suffused with orange and fawn, and the latter a deep bright crimson with light salmon centre. The new Rose catalogue of the firm, just published, should be consulted by those who are growers of Roses, and who would keep up with the advances that are being made.

## Pollination in Orchards.

It has been frequently noticed that in large plantations of one particular variety of Apple or Pear the quantity of fruit produced greatly diminishes from the outside of the plantation towards its centre, and the explanation apparently is that foreign pollen, that is, pollen from another variety of Apple or Pear, as the case may be, is necessary for the proper fertilisation of the ovules, in order that fruit may be set at all. It seems also that incomplete fertilisation may also take place, owing possibly to weakness in the pollen of the particular variety, resulting in the formation of misshapen or malformed fruit.

The fertilisation of the ovules depends chiefly upon three factors:—

1. The occurrence of suitable weather conditions at the time of the receptivity of the stigma and the ripening of the pollen.

2. In the case of self-sterile varieties, the presence of bees or other insects to carry pollen from one flower to another. Müller gives a list of nine bees visiting flowers of Apple (*Bombus hortorum*, L. ♀ being especially abundant), as well as other insects (seven) visiting the flower for honey or pollen; and a list of six bees (*Apis mellifica*, L. ♀ very abundant), as well as twenty-four other insects visiting the flowers of Pear ("Fert. of Flowers," pp. 238, 239). He also says that if bees fail to visit the flowers, self-fertilisation occurs in each case, but he is presumably speaking of the wild plants, *Pyrus Malus*, L., and *P. communis*, L., and not of a garden variety.

3. In the case of the self-sterile varieties, the presence of plants in the near neighbourhood whose pollen will fertilise the ovules of the self-sterile variety.

This last factor is the one most under the control of the grower, and therefore the one upon which definite knowledge is essential, and though much has been done in America in finding out which are the self-sterile varieties, &c., very few definite experiments carried out on lines which admit of a minimum of error in the result appear to have been conducted, or at least recorded, in this country. American results are not altogether reliable here, owing (1) to the difference in the varieties grown, and (2) the difference in the meteorological conditions.

In an attempt this season to ascertain which varieties of Pears were self-sterile, and therefore not suitable for large plantings by themselves, I tested the following fifteen varieties:—*Bellissime d'Hiver*, *Beurré d'Amanlis*, *Beurré Superfin*, *Catillac*, *Conference*, *Doyenné du Comice*, *Durondeau*, *Easter Beurré*, *Emile d'Heyst*, *Jargonelle*, *Josephine de Malines*, *Louise Bonne of Jersey*, *Pitmaston Duchess*, *Williams' Bon Chrétien*, *Olivier de Serres*. Of these only two, *Conference* and *Durondeau*, set fruit under such conditions that foreign pollen (i.e., pollen of some other var.) was unable to obtain access to the stigmas—i.e., only those two vars. proved self-fertile.

So far the evidence is positive; the evidence with regard to the other thirteen varieties is not conclusive, the weather prevailing at the time possibly interfering with the setting of the fruit. Negative evidence can only be accepted in such cases after a long series of experiments extending over several years with varying climatic conditions. In some cases, although the trees flowered very well, and were growing close to other varieties, only one or two fruits were set, showing that weather conditions interfered greatly with the production of fruit.

Thirteen varieties of Apples were experimented on—*Beauty of Kent*, *Cellini Pippin*, *Cox's Orange*, *Claygate Pearmain*, *Gladstone*, *Lord Derby*, *Lady Sudeley*, *Mannington Pearmain*, *Northern Greening*, *Schoolmaster*, *Stirling Castle*, *Sandringham*, *Sturmer Pippin*, and here again only two varieties set fruit, under conditions precluding the entrance of foreign pollen—*Gladstone* and *Stirling Castle*. Of course, here again, the negative evidence does not conclusively prove that the remaining eleven varieties were self-sterile.

The weather prevailing at the time, high winds and wet, prevented any cross pollination experiments being carried out with accuracy; but it is worth noting that, although the Pear-blossoms are, as a rule, at least, protogynous, yet it frequently happens that one or two of the anthers have shed their pollen before the bud opens; this fact points to the necessity for special care in the choice of flowers for cross pollination.—F. J. C.—(R.H.S. Scientific Committee).

## Town Trees.

(Concluded from page 282.)

### The Acer Tribe.

Like the common Ash, the Mock Plane, or Sycamore (*Acer pseudo-Platanus*), finds way as seeds into backyards, areas, and other confined places in country, and sometimes the sunniest and confined towns, and seedlings spring up with astounding vigour. They are cherished in the small front or back garden or yard, for who does not love the green thing that has sought refuge and appeals for protection? The seedlings grow might and main, embellish the situation, and help purify the atmosphere. Anon they afford shade, become part of the very life of the occupier of the place. If space forbids, the heads are lopped or cropped, always in winter time, and they remain quite satisfactory for a lifetime. Where there be room the young trees mount up quickly to the height of the first floor windows, or even eaves and ridges of two-storied dwellings, when, and sometimes long before, they contract fly (*Aphis aceris*), which strew the ground beneath with honeydew, and the upper surface of the leaves become coated therewith; then this turns black by action of fungus, the leaves being very unsightly, and, worst of all, they curl up, mature, and fall off early, as this season, in September. Black blotch fungus (*Rhytisma acerinum*) also affects the leaves seriously in some seasons, even this, and they fall early in consequence. For these reasons I do not see the merits of Sycamore trees for town planting. The bees are fond of the flowers and their hum may be pleasant to town dwellers; but this is bad when the

Rose, *sulphurea*.

(See reference on page 308)

trees, in my experience, are altogether unfit for place in the smokiest towns. The variegated variety (*A. P. albo-variegata*) holds its own better against smoke and impure air than the green-leaved, and the purple-leaved (*A. P. purpureum*) is not troubled nearly as badly with aphides and black blotch fungus as the type.

The Norway Maple (*A. platanoides*) grows grandly when young, its smooth Plane-like leaves resisting smoky and fume influences well, especially in exposed situations; but when getting at all aged the heat and drought appear too much for it, so that the leaves come littering down far too early in September, especially in a dry and hot season, even in country towns. Similar remark applies to the variegated forms. One of the finest foliaged Norway Maples is Schwedle's (*A. p. Schwedleri*), with deep bronzy-red leaves, very large, the tree being a vigorous grower and most effective.

Different altogether is the large-leaved Maple (*A. macrophyllum*), with its digitately five-palmate, roundish recessed and somewhat three-lobed leaves; not over-hardy perhaps, but enough so for southern and midland counties towns, if not northern, the foliage holding on as persistently as the Planes. The specimens observed have had the advantage of a generous soil, but not better than for the other Maples alluded to, including the Sycamore.

#### Negundo and White Beam.

The Ash-leaved or Maple-like Box Elder (*Negundo aceroides*) forms a spreading tree, grows fast, and is very ornamental. It bears smoke and impure air well, but reflected heat combined with droughty conditions are too much for its powers of resistance, hence begins to litter in August and keeps on right away until frost ends the foliage on the latest growth. The variegated form (*N. a. variegatum*), so much in vogue for suburban planting, is not nearly as hardy, and does not grow so freely as the type after the flush of youth is past, and in not a few cases gets "smaller by degrees and beautifully less," some being leafless at the beginning of September.

The White Beam tree (*Pyrus Aria*) grows luxuriously in confined spaces, always provided there be moisture in the soil, for on a gravelly soil the leaves were curled up and many fallen, even some trees leafless, at the beginning of September. As a small tree it deserves notice from planters, but hardly for streets, as its numerous brightly-tinted berries, however handsome on the trees, are a great nuisance in footways. Similar remark applies to other species of *Pyrus*, and many of them begin littering too early in autumn by their leaves, and the fruits or berries make a mess later on; hence they, with the Thorns, will be passed in this connection; also low trees or shrubs.

#### Oaks in Variety.

Great Britain's predominating tree, the British Oak (*Quercus Robur*), occasionally springs up in backyards and front gardens of town residences, and the seedlings are very healthy and vigorous for a time; but, like the seedling Ash and Sycamore before alluded to, their enemies find them out when 20ft high or before, and they assume an ill-thriven appearance. This year some trees have the lower surface of the leaves almost entirely covered and weighted down by button galls, covered by the insect named *Neuroterus numismatis*. The trees are very unsightly, and the "buttons" in early autumn make a great mess. The sub-species or forms of common Oak, *Q. pedunculata* and *sessiliflora*, are not a whit better, though the latter is rather less affected.

In contrast with the British Oak, the Turkey Oak (*Q. cerris*) has splendid leafage, and the Hungarian Oak (*Q. conferta*) quite equals or rivals it. I cannot say that I am in love with the sometimes almost evergreen forms, the Lucombe and Fulham, but the scarlet Oak (*Q. coccinea*) has not only charms in summer by bright green shining foliage, while in autumn the leaves turn red. Against Oaks in streets there is the objection of acorns, and also that of growing too large and being worse than spoiled by lopping. Pollarding is an altogether different affair, and this practised betimes results in heads which for beauty are matchless.

#### The Walnuts.

The Walnut (*Juglans regia*) has kept its leaves singularly well, but the husks and nuts are against it as a street tree. It also is not hardy enough for northerly and high situations. The black Walnut (*J. nigra*) is a noble tree for towns, though on account of its fruits not commendable for streets.

The much-lauded Black Italian Poplar (*Populus monilifera*) is much affected by rust fungus (*Melampheora populina*), and shedding its leaves wholesale. It has also the defect of losing some of its branches by attacks of a fungus (*Didymosphaeria populina*), and though very bold and deep green in foliage, is not nearly as free-growing and far from as healthy as some other species and varieties which must stand over for consideration with what may be termed the "cream" of trees for town streets.—G. A.

## Victorian Medallists of Honour in Horticulture.

### MR. JOHN T. BENNETT-POË, M.A., V.M.H., &c.

Recently the Council of the Royal Horticultural Society bestowed a Victoria Medal of Honour on Mr. Bennett-Poë, in recognition of his good work in horticulture, and among the flowers. The sixty-first volume of "The Garden" was dedicated to Mr. Bennett-Poë on June 28th of the present year, and from that number we have extracted the following biographical notes.

"Born in County Tipperary, in the year 1846, Mr. Bennett-Poë received his earlier education from tutors at home and at a private school; afterwards at Trinity College, Dublin, there graduating successively B.A. and M.A. He was almost a born gardener, inheriting a love of plants, which became and has continued to be the greatest of his life's interests. Never very robust in health, the open air life of a practical horticulturist has been of great benefit, and has enabled him to acquire a knowledge of plants and of their ways and treatment that is probably surpassed by that of few other living amateurs.

"On settling in London in 1889 Mr. Bennett-Poë was pressed into the active service of the Royal Horticultural Society on the Floral Committee and on the Board of the Chiswick Gardens; serving also for ten years on the Council, for some time as Vice-President. Among his other offices in connection with the Society, he is a Trustee of the Lindley Library, Trustee of the Veitch Memorial, and was formerly Chairman of the Narcissus Committee.

"Mr. Bennett-Poë's services have also been given as judge at the shows of the Royal Horticultural and Royal Botanic Societies, and in the same capacity at shows at Dublin, Cork, and Scarborough. His exhibits of rare and beautiful plants have received many honours, and he is well known as a prizewinning exhibitor of Narcissi, Tulips, Auriculas, and Orchids."

### MR. WILLIAM BATESON, M.A., F.R.S., V.M.H.

Though we are unable to present Mr. Bateson's portrait with the following notes, yet these may be read with interest at this time when considerable attention is being devoted to the problems of heredity in plants and animals. Mr. William Bateson is the chief exponent and most active experimentalist in this country in all that purports to variation, heredity, selection, and other phenomena connected with the evolution of plants and animals. In the Natural History Museum at South Kensington, there is now on view, in the case devoted to objects connected with the most recent research, a practical demonstration of the results of cross-breeding Peas (*Pisum*), which is specially elucidatory of Mendel's law. This exhibit is presented by Mr. Bateson.

In his introductory note to the translation of Gregor Mendel's paper on "Experiments in Plant Hybridisation," published in the Journal of the Royal Horticultural Society, vol. xxvi, 1901, part i., Mr. Bateson writes that:—"The conclusion which stands out as the chief result of Mendel's admirable experiment is, of course, the proof that in respect of certain pairs of differentiating characters, the germ cells of a hybrid, or cross-bred, are *pure*, being carriers and transmitters of either the one character or the other, not both. In so far as Mendel's law applies, therefore, the conclusion is forced upon us that a living organism is a complex of characters, of which some, at least, are dissociable and are capable of being replaced by others. We thus reach the conception of *unit characters* which may be rearranged in the formation of the reproductive cells."

It is in order to test to what extent Mendel's conclusions are found to apply to other characters, and to other plants and animals, that Mr. Bateson has undertaken the experimental work he is now engaged with. Until recently, his studies have been most zoological. His chief contribution to inquiries on the problem of Evolution, was a book published in 1894, under the title "Materials for the Study of Evolution," dealing mostly with zoological subjects.

Some years ago Mr. Bateson began a series of breeding experiments on variation and heredity in animals, using especially poultry and butterflies; and in several species of plants, as for instance *Pisum*, already mentioned. An account of the results thus obtained will shortly be published. In this experimental work, Mr. Bateson has been associated with Miss E. R. Saunders, lecturer on botany at Newnham College, Cambridge.

As secretary of the Evolution Committee of the Royal Society, the subject of these notes has further been endeavouring to promote inquiries of this nature, and to assist in the scientific utilisation of the results obtained by practical men. Breeders and horticulturists are continually engaged in experiments on a large scale, many of which, if recorded in detail, would have a high scientific value.

A sub-committee has been appointed to confer with the Royal

John T. Bennett-Poë, M.A., V.M.H.

Horticultural Society, and to further the objects of the committee so far as horticultural investigation is concerned. It is hoped that some of those who are engaged in practical horticulture may be willing to assist the committee by communicating the results obtained. So far, only a very small beginning has been made. Observations, to be useful, have to be detailed and drawn up on a statistical scale.

Mr. Bateson is a member of the Councils of the Royal Society, and of the Zoological Society. The Royal Horticultural Society lately bestowed on him the blue ribbon of horticulture—The Victoria Medal of Honour. Mr. Bateson is a tall and well-proportioned gentleman, of prepossessing appearance, and endowed with much energy and force of character. He is in the prime of life, and may look forward to very many years of good and useful work, in which we trust that success may attend him, and that many advances may be made.

#### MR. GEORGE MASSEE, V.M.H., F.L.S., &c.

It is our privilege to introduce to the readers of The Journal, a personality to whom gardeners and agriculturists owe a great debt of gratitude, and not only does this apply to practitioners at home, it bears quite as much on producers abroad and in the tropics. Mr. George Massee is in the front rank of living micologists and bacteriologists, and in his illimitable sphere of research, he is convincingly a zealous worker. The meanest fungus is to him possibly more interesting than the loveliest Orchid or the most graceful Briar.

Mr. Massee's first botanical work was plant-collecting in Ecuador and Peru, of which dry countries Charles Darwin writes so interestingly in his "Voyage of a Naturalist." On returning to England, Mr. Massee occupied the position of lecturer on botany to the London University Extension Society, which office he held for some years. He later accepted the newly-created post of principal assistant of Cryptogams in the Herbarium, at the Royal Gardens, Kew. Here he has remained, and the greater portion of his time is occupied in investigating the plant diseases from British and Colonial sources. Quite recently the plant diseases caused by vegetable parasites submitted to the Department of the Board of Agriculture, are sent to Kew for investigation.

Mr. Massee has delivered lectures on phytopathology to the students in the Royal Horticultural Society's gardens at Chiswick and at Kew. He is exceedingly interesting in this rôle, and imparts his knowledge in a lucid manner, which is characterised by an ever-present accompaniment of quiet humour. His "Text Book of Plant Diseases Caused by Cryptogamic Parasites"

published in 1899, is a useful book, and one which every gardener ought to possess and study. Mr. Massee's latest work is one which must have necessitated immense care and patience, as well as wide knowledge and experience of fungi. It is no less than a descriptive list of the Agarics of European countries. The title is "European Fungus Flora: Agaricaceæ." The chief other works of which he is author are "British Fungi," "British Fungus-Flora," and "A Monograph of the Myxogastres." He is president of the Quekett Microscopical Club; chairman of the micological section of the Yorkshire Naturalists' Union; member of the Scottish Cryptogamic Society; member of the New Zealand Institute, and other naturalists' clubs and societies.

The Royal Horticultural Society, through its Council, have recognised the usefulness of the work being done by awarding to Mr. Massee their Victoria Medal of Honour in horticulture.

## Irish Notes.

### The Irish Forestry Excursion.

The first annual excursion of the above society took place in fine weather, at Emo Park, Portarlinton, the ancestral home of the Earls of Portarlinton, within comparatively easy reach of Dublin.

Amongst the company were Dr. Cooper (founder and president), from London, also Mr. Munford, Mr. Galvin, Mount Talbot, Roscommon; Mr. J. Jones, Delgany; Mr. Melville, superintendent, Finsbury Park, London; Mr. Hodson, Mr. J. Carew, Mr. S. Brown, chairman County Council, Naas; Mr. Dick (late of Phoenix Park), who performed the arduous and thankless task of guide; Mr. F. W. Burbidge (curator Trinity College Botanic Gardens), Mr. R. Anderson (superintendent Phoenix Park), Mr. Gallagher (Editor "Farmers' Gazette"), Mr. Fraser, and in the absence of the secretary, Mr. Geoghegan made an excellent eicerone. The first wood entered was locally known as Spire Wood, and largely planted was the well-known Scotch Fir (*Pinus sylvestris*). The finest specimen 4ft from the ground measured 8ft 10in and about 18ft of clear stem before the first fork; the trees were in good condition, the bark free from injury. Some Silver Firs were to be seen, but they evidently did not thrive. Before emerging from this wood there was an enormous amount of under-wood that impeded walking, and suggested a retrograde management in this plantation, whilst the ground was studded with self-sown seedlings of Beech and Scots Fir.

The next visit was to the domain proper. The avenue leading to the gates was approached by rows of Linden trees (*Tilia*

George Massee, V.M.H., F.L.S.

europæa), and were received by the gardener, Mr. Bradbrooke, who kindly pointed out the leading features. Though the domain was densely packed with trees of various kinds, the broad fact to be gleaned was, that the planting was more ornamental than productive. The one pleasant feeling aroused by visiting the woods was the general absence of fungus or insect attack; the Larch plantations besides being fine timber were completely free from blister or *Peziza Wilkommii*, though fairly prevalent in Ireland, and in some quarters renders Larch production an almost impossible task. Though the area covered was fairly large, and though an enjoyable day was spent, yet one must advert to the many good lessons wanting, and which one may hope to glean on future occasions. At all events the Society could see the great defect in Irish forestry, namely, the want of proper forest management, and they should do their utmost to force conviction on those who guard the last vestiges of our national forests, and enable our newer plantations to be placed on a proper footing. Subsequently the party were photographed on the lawn, and drove to the "Imperial Hotel," where dinner was served in excellent style. The chair was taken by Dr. Cooper, and afterwards, several toasts having been proposed and duly replied to, a warm vote of thanks was passed to the Countess of Portarlington for her kindness in placing the woods at the disposal of the society. The party shortly afterwards returned to town, after a very enjoyable outing.

#### The Irish Fruit Conference.

The Irish Board of Agriculture have recently announced to hold a fruit conference in connection with the Cork Exhibition, on October 15 to 17. The schedule states that papers will be read by experts, but the general tone of the topics is not even hinted at. It is very questionable whether this notice is adequate enough to make the conference representative, and it would seem that the object was more to supply an attraction to the exhibition than to deal seriously with the general question of fruit growing. But a fruit conference is eminently required, as several topics require to be decided for the guidance of those intending to grow fruit, namely the best varieties for each county, the kind of soil in which they do best, and the varieties that require a special compost to grow them, for example, the well-known Bramley's Seedling will not do in some parts of County Wicklow without a specially prepared soil. Growers want to know what varieties will do generally in Ireland, and which are suitable for particular soils. The varieties given should likewise be representative of a good succession, and yield a good supply of fruit well into the winter. Growers also wish to know the best modes of keeping fruit in cool houses, of the erection of houses, and internal structure of same. When, however, we turn to the schedule, such a scheme is not covered, but we find merely prizes given for a series of dishes of each kind of fruit. Now, such awards would only bring this display to the level of a local country show, and reveals the fact that the organisers did not grasp the meaning of a conference, otherwise they would have taken the necessary steps to bring a large array of growers together by means of the local horticultural societies. Growers are not going to expense of travelling to Cork and staying there for the best part of a week, without the guarantee of something in the nature of a conference. The schedule ought to say a fruit display.—A. E. O'NEILL.

### CUCUMBERS.

The plants for winter fruiting must be in their places by the middle of October to insure a good supply at Christmas and onwards. Keep them near the glass to ensure a sturdy growth, not allowing them to become root-bound. See that the fermenting material is in a due state of preparation if any had to be employed for bottom heat, and make certain of the heating apparatus being in proper order. A bottom heat of 85deg to 90deg will be safe, but the latter temperature should not be exceeded; if from hot-water pipes a bottom heat of 80deg to 85deg is sufficient.

As there are many failures with winter Cucumbers through disease, it will be necessary to take proper precautions in the way of thorough cleanliness and choice of soil. Turfy loam of a light nature is best, but about 3in thick or less with the turf, and this baked in an oven, or on an iron plate over an improvised furnace formed of loose bricks, being careful not to bake it to a cinder, but only to destroy fungoid germs and nematoid worms, a temperature of 212deg being sufficient.

The eelworms are generally located in the decayed parts of the herbage, and that part should be placed on the hot plate, and when heated through so that the hand cannot be held on the soil side it is cooked enough. This will not injure the compost in the least, while it will certainly kill eelworms, and though somewhat troublesome, is far the best of preventives, as acids render the soil more or less sterile for a time, and mineral salts have a tendency to induce grossness in the plants, especially those of a retrograde nature.—A.

## NOTES

## NOTICES

#### New Park for Willesden.

To provide another open space for the public, the Willesden (London) District Council has acquired some acres of land at Stonebridge Park, a portion of the parish now being rapidly developed by residential dwellings. This new recreation ground will be opened on Saturday, October 4.

#### York Chrysanthemum Show.

This important fixture takes place on November 12 and the two following days. Numerous pieces of plate and valuable money prizes are being offered for plants, flowers, fruits, and vegetables. Entries close on November 5, and communication should be made for answers to inquiries to the secretary, Mr. Geo. F. W. Oman, 38, Petergate, York.

#### A New Calla.

A Blankenbourg (Germany) horticulturist reports to a French gardening paper that he has presented before the Royal Horticultural Society of Prussia, a new Calla, or correctly, *Richardia*—a cross between *R. Elliottiana* and *R. Adami*. The spathe is citron yellow, with a purple shaded base, and the foliage possesses transparent spots. It is hardier than *C. Elliottiana*, and is to be placed in commerce under the name of *R. Solfaterre*.

#### Royal Horticultural Society.

The next fruit and flower show of the Royal Horticultural Society will be held on Tuesday, October 7, in the Drill Hall, Buckingham Gate, Westminster, 1-5 p.m. A lecture on "Experiments with Chemical and other Manures" will be given by Mr. F. W. E. Shrivell, at 3 o'clock. At a general meeting of the Royal Horticultural Society held on Tuesday, September 23, thirty-six new Fellows were elected, making a total of 934 elected since the beginning of the present year.

#### National Dahlia Society.

Arrangements are being made for the holding of a Conference on the judging of Cactus Dahlias in September, 1903, on the afternoon of the first day of the annual exhibition. The Conference will be opened by a paper from Mr. C. G. Wyatt. The exhibition will be held at the Drill Hall, Buckingham Gate, the arrangements being similar to those for the exhibition held recently, and the Conference will take the place of the fortnightly lecture of the Royal Horticultural Society. Several new decorative classes will be added to the schedule for next year.

#### The Year's Weather.

The Meteorological Department at Greenwich Observatory announces that the rainfall for the first eight months of the year was 1.786in below the average. Of sunshine during the eight months there has been a falling off of 313.8 hours, or about an hour and a quarter each day compared with the same period last year. The record of temperature does not show the summer months in any better light. The mean for the eight months is 49.3deg, which is 1.1deg below the average. One may well agree with the general verdict upon the year's weather to date:—Rainfall, below the average; great fall in sunshine; very cloudy summer; a cloudy year.

#### Examination in Horticulture, 1903.

The Royal Horticultural Society will hold its annual examination in the principles and practice of horticulture on Wednesday, April 22, 1903. The examination will be held simultaneously in as many different centres in Great Britain and Ireland as circumstances may demand. A centre can be established wherever a magistrate, clergyman, schoolmaster or other responsible person accustomed to examinations will consent to act on the society's behalf in accordance with the rules laid down for its conduct. No limit as to age, position or previous training of the candidate will be imposed. The new syllabus is now ready, and intending candidates should send a penny stamp for a copy of it. Copies of the examination questions set by the Society's examiners in previous years—price 1s., complete—can also be obtained on application to the Secretary, R.H.S., 117, Victoria Street, London, S.W.

**National Sweet Pea Society.**

An extraordinary general meeting will be held at the Hotel Windsor, on Tuesday, October 7, at 4 p.m., to consider a proposed alteration of Rule 7.

**Apples in Texas.**

The Red River fruit belt in northern Texas is proving to grow Apples very successfully. The varieties most grown, named in order of popularity, are Ben Davis, Jonathan, Red June, Early Harvest, Black Twig, Winesop and Gano, with many other varieties on trial.

**Importations of Sweet Potatoes.**

Large quantities of the Sweet Potato (*Ipomæa Batatas*) are about to be imported to this country from Barbados, "by special request of the Imperial Department of Agriculture for the West Indies. They will be shipped in barrels of about 1cwt. to Pink and Sons, at Portsmouth. Sweet Potatoes are cooked by boiling, roasting, and broiling, and can be used in pies, rissoles, and other dishes."

**Assisting Infirm Gardeners.**

As a practical instance of what might be done in the cause of charity by the clergy of the Church, we would cite the efforts yearly made by the Rev. W. Wilks, M.A., Vicar of Shirley, on behalf of the Gardeners' Royal Benevolent Institution. We quote from the "Croydon Advertiser," of September 27:—"Shirley Church Harvest Thanksgiving, October 5, 1902. Sermon at 11 o'clock a.m., by the Rev. Prof. George Henslow, M.A. Offertories throughout the day for the Gardeners' Royal Benevolent Institution." At other harvest thanksgivings, special appeals in aid of the funds of this charity might quite appropriately be made.

**Changes at Kew.**

Mr. Frank Garrett, for about fifteen years foreman of the Greenhouse and Ornamental Department at Kew, has been appointed head gardener to the Duke of Marlborough, at Blenheim, Woodstock, in succession to Mr. Whellans. At Kew, Mr. Garrett's vacancy will be filled by Mr. A. Osborn, for some time deputy foreman in the Ferneries. Mr. Dawe, till recently the deputy foreman in the Arboretum Pits, has been appointed to a responsible post in Uganda, and his position at Kew is filled by Mr. F. Stayner, late of Messrs. Veitch's. The Royal Gardens' control shortly will be transferred from the Board of Works to the Board of Agriculture.

**Gardeners' Winter Session at Ipswich.**

The third session of the Ipswich District Gardeners' and 'Amateurs' Association till the end of the present year will include lectures as follows:—October 2.—Garden Roses, by Mr. F. Cant, Colchester; October 16.—Germination of a Seed, by Mr. A. Martinielli, illustrated by specimens and drawings; November 6.—Spring Bedding, by Mr. I. Battram, Oakland Gardens, Ipswich; November 20.—Discussion on Chrysanthemums, &c. December 4.—Carnations, Tree and Malmaison, by Mr. W. E. Close, Holy Wells Gardens; December 18.—The Sweet Pea Family, by Mr. S. J. Batchelder. The hon. secretary is Mr. W. E. Close, of Holy Wells Gardens.

**Mr. W. H. Patterson.**

The recent changes and reduction in staff at the Swanley Horticultural College have brought promotion for the Superintendent, Mr. W. H. Patterson, for he has accepted the post of lecturer in horticulture, and keeper of the gardens to the senate of University College, Reading. Though he had been but a short while at Swanley, having accepted a six months' engagement to reorganise the garden work, great changes and improvements were effected in the time, and it seems a pity the committee should consider it necessary to adopt the retrogressive step of excluding men students, for if horticulture is to advance greatly by means of training colleges, it is to the men that most of the future depends. Fortunately Reading fully recognised this fact, and the work will be arranged for the benefit of those who are taking up the subject as a profession. Mr. Patterson, who assisted in the production of "Cassell's Dictionary of Gardening," under the editorship of Mr. W. P. Wright, has received botanical and horticultural training at the Technical College, Colchester, the Technical Laboratories of the Essex County Council as well as in Kew, market gardens, private places and nurseries.

**Canadian Florists 12,000 Strong.**

Mr. Joseph Bennett, of Montreal, the retiring president of the Canadian Horticultural Association, gives it as his belief that so many as 12,000 persons are employed in the florists' business in the Dominion of Canada.

**Medal Award.**

"I see in the Journal of September 25 you state that a silver Knightian Medal was given by R.H.S. for the collection of fruit from Tilgate, Crawley. It should have been Silver-Gilt Knightian. Will you please correct it in the next issue?"—E. N.

**Lost in the Post.**

We have received a label bearing the postmark "Mayfield, Sussex," and dated September 25, and additionally stamped thus by the post office officials: "Found in E.C. without contents." The address is correctly and clearly written on the label, which must have become unclosed from the parcel.

**United Horticultural Provident Society.**

The annual dinner of this society as previously announced to be held on Tuesday, October 7, has been unavoidably postponed. It will now be held at the Holborn Restaurant (Throne Room), High Holborn, W.C., on Thursday, October 16, at 6.30 p.m. Arthur W. Sutton, Esq., F.L.S., V.M.H., will preside.

**Meetings at Cardiff.**

The members of the Cardiff Gardeners' Association have drawn up another bright, varied and useful syllabus of lectures to be delivered during the coming months at their meetings. Competitions for plants, vegetables and fruits are arranged for three of the evenings. The hon. secretary is Mr. J. Julian, 15, Bertram Street, Roath.

**Ascot Chrysanthemum Exhibition.**

The Ascot, Sunninghill, Sunningdale and District Horticultural Society will hold its eighteenth annual exhibition of Chrysanthemums and other autumnal flowers, with fruits and vegetables, on Wednesday and Thursday, November 5 and 6. There are three good open classes for groups; schedules may be had from Mr. H. R. Attfield, Ascot.

**Torquay Gardeners' Association.**

The programme of essays and lectures for 1902-03, to be given before the members of the above, has been lately published. Many of the lectures are to be of a scientific character, on the subject of plant life. Prizes are offered in certain classes set apart for each of the meetings. The hon. assistant secretary is Mr. George Lee, The Gardens, Upton Leigh, Torquay.

**Seed Potatoes [for South Africa.**

From "South Africa" for September 20, we learn that a Mr. W. J. Malden, who is said to have made a study of this esculent, writes protesting against the announced intention to get supplies of Potatoes for planting purposes in the newly-acquired South African colonies from Madagascar and the Soudan, the reason for selecting these countries to supply the sets being that it is supposed they are "acclimatised" to South African conditions. The South Africans will find these relatively just about as useful as the worn-out remounts which found their way to South Africa during the war, and it is hoped someone will be led to stop such an unscientific and unpractical step as the using of "worn-out or acclimatised" Potatoes. Otherwise, before the stocks sent out can possibly be developed to quantities that can substantially help the country they will have broken down altogether. New varieties are desirable.

**Meeting at Shirley, Hants.**

The following is a list of the awards made for exhibits on September 22, at the Gardeners' meeting:—Certificate of Merit to Mr. Jno. Miles for wasps' nests; W. H. Rogers and Son, collection of Roses (very fine), F.C.C.; Mr. F. Cozens, two very pretty seedling Pompon Dahlias, F.C.C.; twenty-four Cactus, V.H.C.; and twelve Show H.C. Mr. Wilcox, V.H.C. for collection of Cactus Dahlias, and a dish of Strawberry (St. Joseph) from the open. Mr. B. Ladhams, V.H.C. for a very fine stand of cut blooms; and Mr. Tomsett commended for twelve single Asters. A hearty vote of thanks was given to Mr. Miles for his address on wasps, also to the exhibitors and to the chairman for presiding. The next lecture will be given on October 20, by Mr. James Hudson, V.M.H., Gunnersbury Park, Acton, W., on the Cultivation of Figs.—J. M.

## Afternoon.

Rest.—But the rest is not enjoyed unless the morning and quite the early part of it has been filled with good useful work. Idlers have no right to an afternoon. I only wish that all of us could put away our work and cares with the morning toil. To some of us afternoon only comes very late in life; to some of us never. A perfect type of afternoon comes in with St. Michael; such a sweet calm, such a peaceful, restful feeling in the air. There is none of the alertness of spring, no biting, cutting east winds; rather the soft, damp breezes of the west, the morning mists that hang long and close in early. If there is a touch of frost it soon fades away; the days are rainless, indeed, rather too rainless for these poor town folk with their depleted reservoirs. The dew is thick on grass and hedge, and glistens in the mellow light. The scents of autumn cannot be described by the word "sweet," they are aromatic, and appeal to the senses far more than do mere sweetnesses.

It is said that only those of noble birth can detect the scent of the dying Strawberry leaf, but a very plebeian can enjoy the scents of the autumn garden and field. I am always so glad to welcome the pungent Chrysanthemum, the late Mignonette, the homely Turnip, and, above all, the slightly acrid smell of burning weeds and rubbish. We have not reached that point where decay becomes apparent, it is only afternoon yet. The lawns are green, the flower borders intensely bright and gay with all vivid colours. As the season wanes the colours deepen. There are flaming reds, gorgeous crimsons, brilliant purples, burning ambers, golden yellows, and warm, rich browns. I must not forget the jet black of the Elder and the purple-black of the Sloe. For wonderful shades of colours, commend me to the Fungi tribe as found in deep woods, and do not forget the little white deliciously flavoured "buttons" of the field. Talk of Mushrooms from beds! Well, if you have nothing better be content; but get up with me in the uncertain twilight, and let us gather fresh from their grassy bed, soaking in dew, the little natural-born Mushrooms. If you are honest you will say which has the better flavour cooked.

I do not know any pursuit so alluring as the pursuit of the Mushroom. You have so many surprises and so many disappointments, and there is such a feeling of satisfaction when you have filled your basket. I wager you come home with an enormous appetite, and also with very wet boots! Never mind, they will dry, and you have filled your lungs with good, fresh air, and exercised your muscles (especially those in the small of the back). Ought I to say a word about caution? I do not know. If you have not the gift to distinguish the real from the false I cannot put it into you.

Now is the time for the Red Admirals, the Tortoiseshells, the Peacock, the Painted Lady—they are all dressed in autumnal tints, and so harmonise with giant Sunflowers, the Dahlia, and the "Daisy of St. Michael." How that Daisy has become legion! In my younger days it was such an undecided mauve, and generally imperfect in shape; now you are met with improved varieties on every hand. My Holly tree is more than "well set" with berries, on the north side, and the last year's berries lingered till mid August. I suppose the birds had better and juicier fruit. One funny part I noticed was that they freely ate of the bright coloured Victoria Plum, but left the more luscious Green Gage severely alone. How was that? Did other people notice the same fact?

Talking of Plums, which are my "perk," I had only about 10st of Green Gages to sell, as against 40 last year; and of a little rose-coloured Plum 15lb, as against 20st. It has made a difference to my pocket. We have eaten our last Apple pie, that is, of Apples of home production. I cannot put Pears into a pie, nor yet into mince-meat. This has been a Pear year here, and so I indulge the family with stewed Pears, treated with Elder fruit syrup. I give this recipe gratis. The only difficulty I find is that we cannot cook enough Pears for our needs. There is a great call on the stock. I wish it were all afternoon. That sounds as though I were idle; but no, only tired. I should like to lay down my burden, as all Nature is doing, and rest. You grow while you sleep, and wake with fresh vigour. I should like to keep a year of Sabbaths; I think my work would be better afterwards.

Even down here in the heart of the sweet country we are beginning to have city notions and losing somewhat of

our calm. I know there are people who think our life lethargic, but because ours is different they cannot gauge it, and I fancy we have as much to show at the end of the year as the bustling town dweller. At any rate, we oftener see the sun rise, and have done a good day's work before office or shop is opened. We can afford to rest with the set of sun, and to take an occasional holiday in the afternoon of the year.—THE MISSUS.

## Odd Notes.

### Flowers for Church Decoration.

Flowers are never out of place in beautifying a church or a chapel, except when the use of them is overdone, or inartistically carried out. Using too many, or huddling them together, is bound to have a bad effect, and by no means should it be countenanced. Glaring colours are out of place, though in harvest festivals the use of bright colours, such as red and yellow, may be employed in various arrangements with telling effect. Among the flowers available are Cactus and Pompon Dahlias, late-blooming forms of Helianthus, Pyrethrum uliginosum, Salvias, white, mauve, yellow, and white Chrysanthemums.

### Plants for Church Decoration.

Among foliage plants, Palms, such as the Kentias, and various forms of Adiantums among Ferns, are extremely useful. No better flowering plants in pots can be used than white Chrysanthemums, chief of which at the present season is Madame C. Desgranges. It is dwarf in habit, and specially chaste and pure in colour.

### Expensive Bulbs.

Large sums of money are spent in various ways nowadays, gardening having some enthusiasts in its ranks who can indulge in novelties in the shape of new bulbs and plants. Of the former there are some high-priced bulbs of Narcissi catalogued at £21, £20, 10 guineas, 7 guineas, and 5 guineas.

### Cheap Bulbs.

Although the newest and choicest varieties of Narcissi and other bulbs are naturally dear when first introduced, it is gratifying to know that by naturally increasing, they in time become plentiful and cheap, losing none of their characteristics in the process of multiplying. The varieties of Narcissi are specially amenable to rapid increase by cultivation, hence it is that now there are quite a number of excellent Daffodils which may be obtained from bulb merchants at a cheap rate for extensive planting. The pages of the bulb number and other numbers of the Journal testify to this.

### Cinerarias.

The weather has been excellent for Cinerarias, and they have made rapid growth of foliage and abundant roots. Plants in small pots should be transferred to larger before they become pot-bound. On the appearance of grub in the leaf, crush the insects. Green fly must be destroyed by nicotine fumes, dosing them when the foliage is dry.

### Lifting Salvias.

Salvia splendens growing outdoors may be readily lifted and potted for blooming in the greenhouse. These plants make quite an effective display of rich scarlet blooms for a considerable period, which may be extended when the colder weather arrives by subjecting the plants to a little heat under light conditions.—E. D. S.

## NYMPHÆA STELLATA AT GUNNERSBURY.

The gardens of Leopold de Rothschild, Esq., at Gunnersbury House, Acton, Middlesex, under the charge of Mr. James Hudson, are famed for a number of specialities, including the wall-gardening, the fruit-growing, the possession of a Japanese garden as a feature, also specimen scented Pelargoniums, Roses, the "Bamboo" collection, and, to conclude with, the unrivalled Water Lilies. *N. stellata* and *N. s. pulcherrima* are cultivated both under frames such as that shown in the illustration (from a photograph by Mr. J. Gregory, of Croydon) and also during summer in an open-air basin specially constructed for them in the recently formed Japanese garden, the water within which is warm, being conveyed in galvanised lin pipes covered with felt and enclosed in drain pipes, from one of the warm houses. The position out of doors is, of course, sheltered, and the plants grow strongly, sending up hosts of their large and beautiful lavender-blue flowers. In the frames much attention is accorded in keeping the leaves, which form dense masses of stalks and blades, free from decaying matter and confervæ. For this purpose the water is skimmed at least once every day with a fine-meshed net. If market men, or at least a few of them, could cultivate the Blue Water Lily with the same success as does Mr. Hudson, the profits from the sale of the dozens of cut flowers which robust plants will produce weekly would, indeed, be very considerable.

## Among the Fruit Trees.

We have heard a great deal this season about the scantiness of the Apple crop, and there can be no doubt that in some orchards and plantations the crop is a lighter one than it has been for years; on the other hand many trees may be met with laden with good, though not very highly coloured, fruits. I have read several reports of the fruit crops in Warwickshire, and each seems to indicate that the Apple crop is a complete failure. Such reports do not by any means give an accurate account applicable to the county generally, though they may be true of certain localities. In some of the warmer districts fruit of all descriptions is very scarce, while in the colder ones Apple and Plum trees are as a rule, carrying good crops. Another point I have noticed is that isolated trees, the branches of which have been kept fairly thin, are fruiting better than those in more sheltered positions. These things seem to indicate that where full exposure retarded the blossom buds, they were just late

like the present. When it is done during the first week in August the cut-back shoots do not often start into growth again, but they sometimes will. It is, therefore, scarcely safe to cut the side shoots closely upon spur-pruned trees. This necessitates going over them again during the autumn or winter. Pruning during September, however, answers the purpose of summer and winter pruning too, as the shoots may be cut back to any point without fear of their starting again, and while the leaves are yet on the trees, it is easy to see exactly how much thinning is necessary. Some maintain that trees cannot be completely pruned until the fruit has been gathered, and this is certainly true of any which have been neglected, because many of the bearing shoots will need cutting away in consequence of being worn out, or to allow more light to penetrate to the inner branches. Such cases are, therefore, exceptions to the rule, that pruning can be completed now instead of during the winter. On the other hand, when the thinning of the shoots is regularly performed each year as a rule only the young wood requires to be removed or shortened; this, there-

*Nymphaea stellata* at Gunnersbury.

enough to escape the May frosts. I am more than ever convinced of the wisdom of planting on upland sites rather than in the lowlands, even when it has to be done at a disadvantage with regard to soil.

A greater amount of sunshine throughout the summer would have been decidedly beneficial for fruit trees, but I question if we have had too much rain. Two or three dry seasons previously had the effect of greatly limiting the growth of trees, causing them in innumerable instances to become stunted. Fruit trees which continue in that condition for long, may bear well for a few years, but the fruit gets smaller, and the trees become weaker each year, until for a time they are almost worthless, unless special methods of feeding are adopted. The copious rains of 1902 have promoted growth in a remarkable degree, and when the trees get suitable treatment there is no reason why that growth should not yet become well ripened, as a fine late September and October always benefits fruit trees immensely. Raisers of trees have, no doubt, blessed the rains of early summer, as young trees have made more growth since then than they sometimes do in two years.

Summer pruning is of special benefit during seasons

fore, can be done better now than later on, because it lets in the light to ripen both wood and fruit. Young shoots which are not required should be cut back to within two or three buds of their base. When the terminal shoots on a branch are strong and sturdy they need no shortening. If they are long and thin, in fact not self-supporting, shorten them back moderately, not hard, as some pruners cannot resist the temptation of doing, and as a result get several strong shoots the following year. When a shoot is very weak cut it back hard. Any shoots which are still growing freely at the points should have the soft portion removed, even if they are strong and erect and do not require shortening on that account. Varieties like Lady Sudeley, which fruit on the tips of the shoots, should have the ends of the leaders removed, the side shoots being thinned, and those retained left unshortened.

A good many controversies have been waged in regard to this point, viz.: Will Apple or Pear trees produce a shoot on which fruit buds will form during the same year (except on the points)? Of course they will. It just depends upon the variety. Early sorts often do this, but late ones seldom.—WARWICK.

## Peaches and Nectarines.

### Their Classification and Selection of Varieties.

(Concluded from page 294.)

Following the classified list, with original illustrations of my own, the lists of varieties of the Peach and Nectarine as under, may be found useful to those who are interested in the culture of these delicious fruits.

#### SELECTIONS OF PEACHES AND NECTARINES. PEACHES.

##### I.—Very Early Varieties. Season: Mid-July to early August.

|                |              |
|----------------|--------------|
| Alexander      | Early Louise |
| Amsden June    | Early Rivers |
| Early Beatrice | Waterloo     |

##### II.—Second-early Varieties. Season: Beginning to Middle of August

|                       |                      |
|-----------------------|----------------------|
| A Bec                 | Early York           |
| Condor                | Hale's Early         |
| Dagmar                | Large Early Mignonne |
| Early Alfred          | Merlin               |
| Early Grosse Mignonne | Rivers' Early York   |

##### III.—Early Mid-season Varieties. Season: Middle to end of August.

|                  |                 |
|------------------|-----------------|
| Acton Scott      | Dr. Hogg        |
| Belle de Doué    | Golden Rathripe |
| Crawford's Early | Magdala         |
| Crimson Galande  | Sulhamstead     |
| Early Silver     |                 |

##### IV.—Main Mid-season Varieties. Season: Beginning to the middle of September.

|                      |                 |
|----------------------|-----------------|
| Alexandra Noblesse   | Grosse Mignonne |
| Bellegarde (Galande) | Noblesse        |
| Belle Beauce         | Red Magdalen    |
| Dymond               | Royal George    |
| Exquisite            | Stirling Castle |
| Goshawk              | Violette Hative |

##### V.—Late Varieties. Season: Middle to end of September.

|                      |                   |
|----------------------|-------------------|
| Albatross            | Prince of Wales   |
| Barrington           | Princess of Wales |
| Late Admirable       | Raymaekers        |
| Marquis of Downshire | Sea Eagle         |

##### VI.—Latest Varieties. Season: End of September to middle of October.

|                 |                     |
|-----------------|---------------------|
| Comet           | Lord Palmerston     |
| Desse Tardive   | Nectarine Peach     |
| Gladstone       | Osprey              |
| Golden Eagle    | Salwey              |
| Lady Palmerston | Téton de Venus      |
| Late Devonian   | Walburton Admirable |

#### NECTARINES.

##### I.—Earliest Varieties. Season: End of July to middle of August.

|              |                     |
|--------------|---------------------|
| Advance      | Goldoni             |
| Cardinal     | Lord Napier         |
| Early Rivers | Précoce de Croncels |

##### II.—Second-early Varieties. Season: Middle to end of August.

|                    |                  |
|--------------------|------------------|
| Darwin             | Pitmaston Orange |
| Downton            | Rivers' Orange   |
| Hardwicke Seedling | Rivers' White    |
| Improved Downton   | Stanwick Elrue   |
| Murrey             | White            |

##### III.—Mid-season Varieties. Season: Beginning to middle of September.

|               |                 |
|---------------|-----------------|
| Albert        | Humboldt        |
| Albert Victor | Newton          |
| Balgowan      | Oldenburg       |
| Byron         | Pineapple       |
| Elrue         | Violette Hative |
| Dryden        |                 |

##### IV.—Late Varieties. Season: Middle of September to early October.

|                 |           |
|-----------------|-----------|
| Galopin         | Spencer   |
| Milton          | Victoria. |
| Prince of Wales |           |

#### SELECTIONS OF PEACHES FOR VARIOUS PURPOSES.

Varieties for growing against a south wall in all but cold localities, named in their order of ripening.

##### Twelve Varieties.

|                 |                    |

--G. ABBEY.

## White Heathers.

At present *Erica cinerea*, the fine-leaved Heath, has the most beautiful variations of tone to be found in any one of our hardy Heaths. In the *Calluna*, the Heather or Ling, there are fewer good colours, the tones in some of the varieties being somewhat dull, although effective enough when seen in masses. Few plants show such a diverse habit as the Heather, and what with dwarf and tall, spreading and erect, variegated leaved, and varieties with flowers from pure white to deep crimson, and many shades between, one may have a rich display of colour, with much interest in the autumnal garden from the presence of this one moorland flower and its varied forms alone. If the choicest of forms were selected, such would surely be the white Heathers, and by these are meant the white flowered *Callunas*, for it may be well to refer to the British *Ericas* as Heaths. *Calluna v. dumosa*, is of dumpy, stiff habit, as neat as a trimmed Box edging, and the earliest of all white Heathers to commence flowering. The similar stiff habit is seen in the varieties *Hammondi*, *tomentosa alba*, and *Serli*, although not to the same extent; and while *dumosa* is a very dwarf plant, these three white Heathers rise in a fastigiate way to several feet in height. One of the prettiest Heathers is *C. vulgaris alba*. It is much looser in growth than those already mentioned, and is dwarf without being stiff. This is an elegant rock garden plant. At the recent Caledonian Flower Show, Mr. Hayes, nurseryman, Keswick, included in a stand of Hardy Heaths and Heathers a charming seedling *Calluna*. Its well chosen name is *Calluna vulgaris gracilis*. It is a spreading plant, with numerous very slender shoots, that are well wreathed with blossom. The diffuse habit of this seedling will render it an admirable companion and contrast to the sturdier varieties, while none could wish for a better representative of the Scotch Heather with which to adorn the rockery or garden.—D. S. FISH.

## Gadding and Gathering.

"HERE AWA', THERE AWA'."

For many generations now, the Rivers of Sawbridgeworth, in Hertfordshire, have cultivated fruit and farmed their extensive estate in that picturesque district. Their work continues still on the lines that have placed the firm high and secure in its reputation for quality in the stock produced. New orchards of trees that are readily saleable take the place of those that have gone before, and even extra ground has been taken under fruit culture during the past few years. The older orchards are remarkably fruitful, especially the Plums, and so are some of the Apples, even in this unfavourable year; but the promise all round at the flowering time was rosy indeed, till frost withered both flowers and hopes.

### Varieties of Plums.

Many acres are devoted to orchards of standard trees, the ground beneath them being kept clean by surface culture. Plums and Apples are grown thus extensively with Currants occasionally beneath and between the lines of well developed trees. At the time of my visit during the last week in August, Czar Plums were being gathered from the trees, and tons each day were despatched to the London and Birmingham markets, where good prices were accorded. Czar Plum has been heavy this year at Sawbridgeworth. Monarch promised excellently. This is an oft decried variety, and private gardeners are said to affirm that they fail to fruit it. Under genuine orchard-culture on the Rivers' estate it ropes the branchlets heavily with handsome fruits, and is consistently a successful cropper. Grand Duke was seen in splendid condition, and affords a good late dessert Plum for walls. In normal seasons fruits ripen in the middle of October, and besides being very large, the flavour is altogether excellent. Diamond, a good black cooking Plum, for use at the end of this month, is hardy, vigorous, and prolific, and the sight of a "screen-belt" of it bearing prolifically, gave one more confidence than before, if that were needed, in its attributes of hardiness. Williams' Golden Gage, a big, handsome Plum, crops moderately one year, and generally misses the next; it may be less popular on that account. Sultan is an early kitchen Plum, with large round fruits of a dark red colour, and yields a full crop regularly. Another reliable variety for orchard culture is Autumn Compôte. It may be seen in a well-developed state at the present time (middle of September), and begins now to yield its handsome red fruits. Grand Duke is a seedling from it.

Pershores, of course, require no description, but is it generally known that serviceable fruiting trees of the variety are readily attained from suckers? Their habit, when developed, however, causes them to produce suckers luxuriantly, which places them somewhat under a ban. Still, among Plums, comes Belle de Louvain, a dark purple kitchen sort, in use as August closes. This has also yielded satisfactorily in a poor fruit year in the orchards, and so has the Early Orleans, which was being gathered a month ago. Its agreeable, juicy character is appreciated. Fruiting on the borders of the plantations was the common Damson, the true old variety, which must recall to many minds the orchard scenes of one's earliest years.

The late Mr. Thomas Rivers raised a large number of seedling Plums, among which are the names of most of those I have mentioned. His heirs to-day continue the work of crossing and raising. Deeply set amidst an orchard of trees of a newer generation, stands the original Early Rivers Plum bearing an inscription which informs the visitor that:—

This is the original tree of the  
Early Prolific, or Early Rivers Plum,  
raised by Thomas Rivers in 1834.

The gnarled patriarch (for Plums are not famed for longevity) is lichen-covered, having two main trunks and others branching from them, these being propped up on two or three sides. The variety is a very early kitchen Plum, and generally well known. Under glass, in pots, the Early Transparent Gage delighted the eyes and tempted the palate, for it is an undoubted gem amongst early Gage Plums. Transparent Gage ripens some days later.

In season at the present time are Bryanston Gage, a round, greenish-yellow, juicy sample; Denniston's Superb, which we find fruiting well on a gravelly loam, and trained to a south wall. It is robust and a free grower. The fruits are greenish-amber, of large size for a Gage, round in form, with a sweet, juicy flesh. Reine Claude de Bavay, comes into use now, and furnishes another variety of fruitful character, and generally dependable. A new Gage is the Reine Claude du Comte Atthem, a very fine, round and red, late Plum, with fruits of good size, firm and excellently flavoured. Mr. S. T. Wright finds it succeed satisfactorily on his dry, sandy soil at Chiswick, and speaks in its favour. The same remarks apply to the early ripening McLaughlin's Gage, a greenish-yellow American Plum of merit.

Of the dessert Plums not already mentioned, I may name the lovely little Coe's Golden Drop; the popular Jefferson, good for any garden; Kirke's, which, if memory serves us right, was disqualified in a class at the fruit show last week, and stated to

be "a Gage Plum." The large, deep blue-purple fruits are very beautiful on a dinner table, and delicious for dessert. The tree is hardy and a splendid cropper, doing well on gravelly loams in the north. Washington is still another handsome and good September dessert Plum. Added to the culinary varieties may be named the Red and the White Magnum Bonums.

#### Cross-bred Varieties.

The matter of cross-breeding was broached. This is a very necessary work; it is also a remarkably testy and trying one. In the earlier days when varieties of general superior quality were few, the experimentalist's perseverance along this line was pretty sure of a number of successes in the period of a dozen years; but now the field is filling up, and though there are better results obtainable through crossing improved sorts with one another, yet the excellence demanded is very high indeed, and requires much patience, and judgment, and ripe experience on the part of cross-breeders and introducers of new varieties, to ensure any advance. A variety is crossed this year at the flowering time. Presuming that the cross is effective and fruit has ripened, the seeds are sown. They germinate, and the seedlings are potted-on. In five years or six, they are yielding fruit, and this has generally to be proved for one or two seasons. That being so, before a selection, and a few trees are ready for commerce, ten years of one's lifetime have gone. Of course, one sterling advance made, one high-class variety gained, during ten years, may well repay the labour; but again, it may not! and in any case the watching and waiting is always exacting.

It was interesting to view the trees left in the brakes from last season's selections. These are the "failures in life" if we may so term them, their co-evals having been drawn off in batches for the supply of customers, while they, from one cause or other, have been passed by, and there they stand, lonesome and separate, one here, another there, at wide intervals apart over the ground, and though they would make good trees if they were required, yet "it would not pay," as Mr. Somers Rivers informed me, to transplant them. They are, therefore, ingloriously consigned to the fire, and the whole brake is replanted with young stock, afresh. Growers may therefore feel assured that they only receive the freshest, best, and most robust of young trees.

#### Care in Budding.

August and early September are the months when budding is actively performed, and many hands were busy, and backs were bent among the Peaches on this occasion. The shoots bearing the buds are tied in little bunches and kept with their cut ends in tiny pails of water. Each variety has a number attached to it which corresponds with a number and name in a book kept by the firm. The stocks to be budded are each in lines 2ft apart, the plants being 1½ft from each other in the rows. The man who is budding takes a bundle of the shoots from the pail, and proceeds to make his cross and vertical cuts, nipping off a bud and smartly inserting it within the stock. Following close upon him is a boy who binds the stock and bud with raffia, and the business is completed. By working constantly during the day, a good budder will insert 1,000 buds. Very few of the buds fail to unite and grow, but should they fail in the case of Apples, Pears, and Plums, there is still a remedy by grafting in March or April. The results in the end are the same, but grafting is a more expensive operation than budding, hence the large fruit growers rely largely on the latter means of propagation.

After budding, the succeeding year's growth is allowed to fully develop, but the shoots are cut back to five buds or so, and the plants may be lifted and set wider apart. If they are intended to be "trained," it is imperative that they be set 2 or 3ft apart either way. As the shoots from the five or six buds advance, they are bent in the desired direction and secured to stakes—as in the case of fan-shaped trees. At the end of the second year from budding, the trees are again shortened in order that they may be better furnished and filled out, and are sold as two-years-trained trees.

Peaches are here in liberal numbers, many as pyramids in pots for this autumn's despatch, and pictures of health and careful training they are. Others are as trained standards for use on walls. These riders are generally planted to cover the top half of a house or wall, while the lower portion is occupied by a dwarf tree, which in time, but not immediately, may require the whole of the wall space. Others are trained as dwarf, bush, or pyramid trees. The bush-trained tree being the natural style of growth with the Peach, is the form recommended to amateurs, or to inexperienced growers, should they wish pot trees, or others for open-air culture free from walls.

#### Trained and Orchard House Trees.

Plums and Cherries may be had as standards, bushes, or pyramids. Apples and Pears are grown in all forms—cordons, dwarfs, pyramids, half-standards, and full-standards, or they may be had trained for espaliers and walls. Feathered Plum trees are mostly sought for by market growers, as the trees, being run up to a single straight stem, and so much as 8ft in height, with top and lateral shoots, can be transformed into almost any form of tree most convenient to the market-men's requirements.

Pot-grown trees in the orchard house were a feature of special interest. Most of the habitués of the James Street Drill Hall meetings have seen the fruitful Sawbridgeworth Gage Plums and other kinds of fruit trees, and the visitors to the Edinburgh Show on the 10th, 11th, and 12th of this month were likewise surprised and delighted to see such fine samples. Some of the trees are over twenty years of age. They stand 8 to 9ft high, and are confined to 12in pots. Each year, just as the leaves are falling, the trees are turned out of their pots, and as much of the surface and exterior soil as possible is clawed off with a small hand fork. The pots having been cleaned and dried, the balls are reinserted, and fresh, good compost is firmly rammed in. By this annual procedure, and by judicious feeding during the fruit-swelling period, the trees remain healthy and yield heavy crops of typical fruits for years. By having these fruiting plants always beside them, the firm is enabled to test their varieties, and to prove that their stock is all true to name. Most of the scions and buds are procured from these orchard house trees. Included in such houses are Cherries, Peaches, Nectarines, Plums, Pears, and Apples.

The vineries contain a great assortment of Grape Vines, many of them old, but so well cared for that they appear as vigorous and fruitful as the younger canes. Young Vines in pots, proved to be stout and well ripened. Oranges, and in fact the whole of the Citrus family, are cultivated and fruited. Even the Kew folks go to Sawbridgeworth occasionally for a species or variety which they require a stock of.

Specimen fruiting trees are protected in a new area with small meshed wire netting, which excludes the tiniest birds. Near by, it was decidedly interesting to see the battalions of pot Peach, Apricot, Cherry, and other trees already ripening off, each specimen ready in another season, wherever it may be despatched to, for fruit-bearing.

A practical and useful system of growing outdoor Pears was pointed out. The trees are grown on the gridiron or similar pattern, horizontally, over a wooden framework. This frame is 1½ft to 2ft from the ground, so that during the flowering period in April, sashes, mats, or tiffany can be fixed above the trees and render them sufficient protection to avoid any injury. By this simple means, grand fruits and good crops can generally be secured, and the trees, moreover, being free in the open, are well-ripened during the autumn.

Nuts are cultivated; also the Wineberry and other novelties, with Strawberries, Medlars, Mulberries, Quinces. Dwarf Prolific Walnuts, and other kinds of fruit. Even osiers for basket making and for tying bundles, are not omitted. One would like to particularise on certain fine varieties of the different fruits, but these may form a subject for another occasion. In concluding these notes, it may be useful to mention the fact that fruit alone does not comprise the subjects of culture at Rivers', for Roses, Conifers, hedge plants, and ornamental shrubs in variety are grown in considerable quantities.—WANDERING WILLIE.

### NORTH IRISH FLORA.

Mr. E. Lloyd Praeger, in his paper before the British Association on the composition of the flora of the north-east of Ireland, said that the counties of Down and Antrim formed the most easterly part of Ireland, and the portion which most nearly approached to Scotland. Their combined area was 2,148 square miles, and their flora numbered 820 species of flowering plants and vascular cryptogams, Antrim yielding 778 species, Down 752; the total flora of Ireland being reckoned at 1,020 species, and the average number occurring in an Irish county, according to present knowledge, at between 630 and 640. Down was formed of slates and granites, Antrim mainly of basalts. Limestone was very sparingly represented, and while the number of calcifuge plants in the flora was large, the calcicole group was poorly represented. With regard to the types employed by Watson to show distribution in Great Britain, there was in the local flora an almost complete representation of British type plants. English type plants were rather poorly represented, and were more plentiful in the Antrim than in the Down flora. Scottish type plants reached in Antrim their maximum for Ireland; in Down they were somewhat fewer. Of Highland type species there was a fair representation as compared with other Irish counties of similar character; Antrim, though of less elevation, contained more Alpine plants than Down. Germanic plants were extremely few in Ireland, being only thirteen in number; of these the district yielded but four. In Atlantic type plants Down and Antrim were comparatively rich. Turning to the types of distribution which the reader had recently proposed for the Irish flora, it was found that the district was naturally very poor in central type plants, which were largely calcicole and marsh species; while Munonian and Conacian species were practically absent. Marginal type plants, on the other hand, were very largely represented, while of Ultonian species Antrim was conspicuously the focus, Down being considerably poorer. Lagenian plants were only tolerably represented, their focus lying further to the southward.

## SENECIO CLIVORUM.

A new Central China and Japanese species, introduced by Messrs. James Veitch and Sons, Limited, Royal Exotic Nurseries, Chelsea, S.W., through their collector, Mr. E. H. Wilson. It is a hardy perennial, growing strongly to a height of 3ft to 4½ft, on moist, grassy spots on the mountains of its native habitats, and flowers about the end of July. The flowers are borne in the manner shown by the drawing on this page. They are orange-yellow in colour, ten or twelve in a head, and 4in across. The large leaves resemble those of the Butter-bur of our own native streams. The plant is likely to become a favourite in gardens, and has already received an Award of Merit when specimens were exhibited before the Floral Committee of the Royal Horticultural Society on August 18, in the James Street Drill Hall. Dr. Augustine Henry has described this species and its allies in the "Gardeners' Chronicle," September 20, 1902.

## Economy.

(Continued from page 239.)

Many men, many minds; a score of masters, twenty different methods of managing men. Let it be understood we are still dealing with the past, and from the loom of memory the shuttle of thought can easily pick up among the dropped threads of life that embodiment of fuss, fume, fret, and flurry, the clever (?), but cranky old gardener. Such a one is clearly presented to mental vision. More than once a friendly labourer's advice was, "Keep out of his way, my boy, he's ravaging round like a ramping lion; hear him, now, bellowing like a bull." Once, and once only, did this man of wrath unbend to his pupil with, "Go in among those Strawberries, boy, and get a good feed," with the qualification to "hurry up and not be all day about it." However, the sweet enjoyment was all too abruptly foreshortened with, "Get out, you little hog." A clever gardener? Yes; at least it was so assumed by those who measured ability by the vituperation of tongue deemed necessary to manage the garden, but more than a suspicion then crossed the youthful mind that there was something wrong, and now it is known as a fact that all was muddle and mismanagement. Constant friction between man and men, and all friction of whatsoever kind means waste. True, these historical sketches of character may not find exact parallels to-day, but history repeats itself under changed forms, and there is still as much difference in men's ruling powers as there is between some noisy old steam thrasher and a powerful engine which awes one by its silent force.

Perhaps the man who really makes the most of his men is somewhat of a rarity. Perhaps not. It is not easy to analyse his character, but its moral influence is plainly seen in the smooth running of the complex machinery of garden management. Each worker seems specially selected for the work he is best adapted to, and is perfect in it by long practice. He has, all unconsciously, perhaps, been made to feel that he fills an important part, and takes a consequent pride and pleasure from that innate sense of responsibility. Implicit trust and confidence imperceptibly grow under such a healthy regime into loyalty of service and devotion to the master's interests. Whip nor spur are needed to urge on in filling the want that occasional high pressure brings; men cheerfully rise responsive to the call; they will, as some have been heard to say, "do anything for such a master;" and for such men, honest, loyal, and true, a master will do all that lays in his power, and fear not any auditing of his labour bill, for a good balance to credit bears witness to his wise rule and economical management.

### The Seedsman's Bill.

*Prima facie* seed order sheets now supplied with catalogues are a boon and blessing to gardeners. No writing out of lists or poring over catalogues that "words of long length and thund'rous sound" should not disgrace our spelling. No troubling of troubled men, no bothering of bothered ones; jot down ones and twos, and so on, of quarts, ounces, packets, and so forth; sign your name, no more, the seedsman does the rest. Handy, however, as the seed list is, and innocent as it looks, it is neither guiltless of aiding and abetting big bills, nor wholly guilty of doing so. This is not fault-finding with our seed merchants, or need there be any suspicion of design to wound their *amour propre*. *Per contra*, it is possible to show that a little more attention paid to this subject would be better for all concerned. Ninety per cent. of complaints about seed germination lay in the fact that proper attention is not paid at that most critical period of a plant's existence—its birth from the embryo—for the simple reason that men handicap themselves by attempting too much and, consequently, accomplish too little. For instance, one of the craft yearly sowed nearly every delicate annual that is listed, and ten times the quantity he could possibly plant, supposing they were

all successfully raised and properly cared for. Why was it? "Oh! M' leddy juist marks doon a' the things she likes, then I mark doon a' the things I want, and de'il tak it—" Rising wrath stanch'd further speech, but the forefinger indexing some scores of pots, pans, and boxes; some with a label only (seeds bad, of course), others as crowded a crop as Mustard and Cress waiting for salvation in the shape of "pricking off," all sorts of congested life, spoke volumes to which the bill would probably add finis, for "M' leddy's vera pernicketty, and she's aye changing." An exceptional case! Granted; yet the same wretched system permeates many gardens in more or less degree.

Impatience defeats its object. Who has not seen complete failures of the great spring-sowing of Broccolis, and "sic like

*Senecio clivorum*.

One-third natural size.

greenies" through sowing too early! Two seasons ago another neighbour rushed round with his tale of woe. "Never a seed up, all failed; no Broccoli, no Cabbage, no Cauliflower, no nothing." He felt very sore; condemned the seedsman. But he felt sorer still when he saw a fine "hit" sown a month later with seeds supplied by the same firm. The best manager in other directions would need to be a miracle monger as well in order to show any balance to his credit. When guided by inclination, instead of governed by reason, men thus play fast and loose with the ethics of economy. So "bad seasons," "bad seeds," "employer's bad taste," anything, in fact, except gardeners' hobbies and the wildest of wild estimates of what is possible and what is impossible are pegs on which to hang every excuse as well as hang themselves. So, "Our remedies oft in ourselves do lie which we ascribe to heaven."—Quizz.

### Grapes Splitting.

This misfortune, for it can hardly come under the designation of disease, appears frequent enough in vineries to make it a cause worthy of investigation. I have given some consideration to the matter for the last few years—indeed, ever since the interesting discussion which took place in the *Journal* between the late Mr. Thomson and Mr. McIndoe. I have encountered not a few curious cases of “cracking” since then, and though in many of them some people would not hesitate to give a reason, yet I feel in the rather peculiar position of being yet “at sea” with regard to the real cause of this evil. I have not only observed the behaviour of Grapes, but also of other fruits, especially out of doors, and here also I am as yet quite unable to arrive at any satisfactory conclusions. I have also, as far as I know, read all that is worth knowing on the subject without faring much better. Probably many of your readers will think me “tremendous dull” in the understanding, which to me in this connection is a matter of no consequence. But to be more specific, I may say that I entertain no doubt that the exciting cause of Grape cracking is superabundant moisture. My difficulty comes in when I begin to inquire how, and in what manner, does this acknowledged general cause act in producing the disastrous effects? I learn this can take place in two ways: first, by endosmosis, and, again, by exosmosis. Can your many able readers throw more light on this mysterious question?—GRAPES.

### Wanted—Inventors.

Under the above heading you published in your issue of September 11 a most interesting article, which I am sure has met a responsive echo in the minds of many practical gardeners. I quite agree with your correspondent that inventors generally have let the garden severely alone in the way of new and time-saving appliances so far as public records go. It does not follow, however, that new methods have not been adopted in some places by men who have realised the necessity of handier and more useful implements. But the reason that they are not more widely known is not because they do not exist, but because the expense of putting them “on the market” is generally more than most gardeners can afford. Take my own case for instance. As head gardener, I have under my care several houses containing Orchids, stove, and greenhouse plants, Melons, Cucumbers, &c., and, as a natural consequence, occasion sometimes arises as how to adopt the best means to improve the various methods now in use, so as to bring about an improvement in the way of lightening labour. I have designed and have in use several useful appliances, such as an improved support for fruits of Melons; also a support for fruits growing in pits and frames. Another is a plant protector, very useful in the Melon and Cucumber houses during the earlier stages of the plants’ growth, when the Melon and Cucumber are so very liable to be attacked and often destroyed by slugs, snails, beetles, and woodlice. We have in use in the Orchid houses here a very useful invention, which insures perfect safety to the plants from the above-named foes. I may state that some of the supports and plant protectors are in use in the Royal Gardens, and have given entire satisfaction. There is no doubt, if one could afford the expense of taking out the necessary patent, and properly advertising these things, they would find a ready sale, and be found of great use to growers of these plants. But, sir, when I wrote to the “Patent Agents,” with the intention of taking out the necessary protections, I was startled to learn what their fees amounted to, besides having to prepare sundry drawings and specifications. The result was that, as my purse could not stand the strain, my “inventions” remain known only to myself and a few friends to whom I have shown them. I would suggest that you, sir, should obtain the services of an “expert,” who for a small fee would advise upon such matters, and thereby lend much-needed assistance to those in the same position as myself. If this is not possible, then, perhaps, you might in one or more articles tell us how to get the best and cheapest way to work, because I cannot but think that the fees demanded by the agent referred to represented to a great extent his own remuneration, and not the mere fees which any intending inventor would have to pay at the Patent Office.—JAS. BARKHAM, Longford Gardens, Havenstreet, I.W.

Mr. H. Muncey in your issue for September 11, furnishes an interesting article and calls for inventions dealing with gardens.

We are not quite so backward as he would suggest, as a perusal of some of the sundriesmen’s lists will show. “H. M.” desires an unbreakable pot. It is already in existence in the U.S.A., being made of papier-mache, and of a terra-cotta colour. However, they are only in small sizes, and mighty expensive at that. Regarding syringes, there can be no improvement, whilst retaining the size necessary to make it convenient to handle. The “Abol” is among the best of its kind, and the aerated sprayer is excellent for insecticides. One thing that requires improvement is the barrow, the greatest instrument of torture in the garden. Give to us a self-balancing, easy running barrow, and we will be thankful.—SQUIB.

[Our correspondent enclosed sketches suggestive of inventions, and these are: (1), a pneumatic-handled spade, with spring to neutralise any jarring effect, and a sliding grip. (2), a one-wheeled barrow (wheel in the centre) to relieve the weight on the trundler’s arms, the handles being placed above the wheel and worked by a lever so as to act either as legs or as handles, as the case required. There would be hooks beneath, for hanging things on when the barrow is full. (3), a broad-toothed rake, convertible into a hoe by slightly pulling out a rod at the side.—ED.]

### Gardeners and Good Manners.

Writing under the extended title, “One Reason why Gardeners should be Educated,” on page 249, your correspondent “Agnos” dilates in a very self-assured manner on the necessity of polish and a gentlemanly address as another essential to the equipment of a fitly trained head gardener. Granted that it is requisite that gardeners be cultured gentlemen, would it not be reasonable that employers who require men with a university form of speech should pay a relative wage and treat them as gentlemen? How many are there at this moment smarting under the injustice, and even cruelty, received at their hands? No amount of mental culture will produce a gentleman. It will but produce a corresponding amount of polish, through which the inner man may at any time break through. How comes it that we find labouring men with no manners as understood by the aristocrat, but with the instincts of gentlemen implanted deep in their moral fibre? If it were not so, such characters as George Elliot’s “Adam Bede,” one of the finest in fiction, would be an utter absurdity. On the other hand, we know only too well that the term nobility, while it may stand for refinement, as equally often, perhaps, means much that is vulgar, low, and degrading. The most elegant superstructure in the world, built on mental culture, is not to be compared to the meanest temple founded on the bed-rock of all real gentlemanly qualities—right principle, which is of the heart, not the intellect, and which is equally as much the birthright of the peasant as the sovereign. In the storm and stress of life the finer sensibilities may, perhaps, become blunter and dull, but never can the manhood be undermined which is so founded.—D. N.

“Agnos” remarks regarding uneducated gardeners are true to a great extent. Quite recently I overheard a garden boy, when questioned by his employer as to what he was doing, reply, “digging the spuds!” However, “Young Gardener” (page 292) should set to work to improve his “ignorance,” as he terms it. No one is past learning, and the educational books are legion. I am acquainted with a young gardener, who received a poor education yet in manners and speech is quite gentlemanly. Moreover, I feel convinced that he will push forward at a far more rapid rate than his prototypes who are too fond of the leaving-off time and sporting attractions. Without a doubt, the man who studies hard possesses a great pull over those who do not. The collegian may succeed more quickly in obtaining a head position, but the outsider may compete with him if he will only use his brains.—T. A. W.

### High Jinks in Ireland.

Referring to the query concerning the reproduction of a photograph of *Dracæna*, which appeared in your *Journal*, page 205, and also to the query by “Quiz” in the *Journal* of September 4, I am sorry I could not have answered sooner. I am obliged to “Quiz” for drawing my attention to the same. The plant in question, or, rather, photo of same, was not “australis,” but “Lindeni.” However, I am not quite sure, as the owner of the original plant has consigned it to the rubbish heap; therefore, I was led to compare the negative and print from same with the well known “Lindeni,” and the balance of evidence would name it “Lindeni,” so that I have made a mistake in naming it “australis.” But the fault of creeping into the avenue of error does not entitle “Quiz” to deduce the cause as of a bibulous condition. re his remarks: “Oh, it was rare old times, I hear, and what with ‘purty’ colleens hovering about, poteen flying around, and elegant Potatoes at sixpence per stone, small wonder that the littlest of little errors might creep into Irish correspondence.” I may as well state for “Quiz’s” benefit that the photograph was sent previous to these “high jinks,” and was likewise taken in

the earlier months of the year, so that "Quiz's" attempt at cheap sarcasm is utterly devoid of an atom of truth, and suggests a form of journalism that does not bear the impress of manly action. Personally, if I desire to ask a question, I should do so under my own name, certainly not under a nom de plume, as the latter course is suggestive of that questionable code of honour that prefers to stab your opponent in the dark than meet him in open combat.—A. O'NEILL.

### The Germination of Ferns.

Recent investigations by some German physiologists show that in the germination of the spores of Ferns, Horsetails, and Mosses, light is an essential factor. They are thus in contrast with the majority of plants, the seeds of which do not require light for the germinating process, or may even be impeded in growth by its effects. A few exceptions, however, occur amongst Ferns, where the absence of light makes no difference. Generally light acts as a stimulus, also it brings about certain chemical changes in the embryo. Within the spores of most Ferns and Mosses sufficient nutriment is lodged to enable them for a while to retain vitality, but the Horsetails, not possessing it, must germinate speedily or the spores die.—J. R. S. C.

### Apple, Peasgood's Nonsuch.

I am rather surprised to find that your esteemed correspondent Mr. W. J. Murphy (page 249), cannot succeed with the above-named Apple. A tree which only cost half-a-crown three years ago at the nursery, and which I planted here, is now bearing a crop of beautiful fruits, as it also did last year, and I know an old tree not many miles from here which bears some of the best specimens I have seen, and which have helped to win prizes at the Crystal Palace and at the local shows. I should advise Mr. Murphy to take the blossoms off the tree if he has not already done so, as they cannot do the tree any good, but probably some harm.—R. M., Babington, Bath.

### Red Spider on Vines.

On page 292 Mr. A. Jefferies, after a long silence, again takes up the above subject, and—to use a well-known metaphor of Dickens—he seems to be "swelling visibly" in contemplating his recent achievement in not being able to kill red spider after having vaporised with XL All at twenty-five times the usual strength. Mr. Jefferies asks me to explain how I managed to destroy similar insects so easily by the aid of XL All? Well, I do not believe in mere repetition; all I have to write about the matter I have already written in my previous communication. It would be quite easy for me to forward to the editor a few Vine leaves covered with red spiders, all quite dead, but that would prove nothing, as it seems that the "hardened criminals" in Essex are not caught—I mean killed—so easily.—H. D.

I do not wish to enter into the discussion between "H. D." and Mr. Jefferies on this all-important subject to gardeners, but I trust that the latter will pardon me for venturing to say that, excellent in detail as the description of the experiment made by him is, it lacks one most essential factor, viz., the state of the atmosphere of the pit, with respect to moisture, in which, and at the time, the experiment was made. When vapourising with nicotine compound, a comparatively dry atmosphere is absolutely necessary, and inattention to this factor frequently makes all the difference between success and failure. In making this statement I do not wish to infer that vapourising with XL All nicotine compound will destroy red spider in all its stages either by one strong, or what is far better and safer, repeated minor doses; but I do wish to emphasise the fact, that a given dose administered in a moist atmosphere containing 90 per cent. of moisture may prove ineffectual, whilst in one containing only 60 per cent. it will prove destructive to insect life.—T. CHALLIS.

We are still waiting in expectancy for that which is destined to be the greatest boon ever yet conferred on a gardener, a compound or article which is perfectly reliable and certain in its destructive powers against "insects," while equally perfect in its harmlessness to the most tender plants. XL All, mentioned by Mr. Jefferies on page 292, perhaps does not claim to be blameless further than others of the many eurative potions which exist for the relief of plant troubles. It, nevertheless, is among the best insect destroyers we yet possess. This we think few people who have given it a fair trial will feel prepared to dispute. But even with the oft-employed tobacco, we find red spider can stand a good deal of the fumes and still keep a steady foot and upright gait. To Adiantums, XL All is a disastrous foe, browning the young fronds in a very short time. It deals death readily and speedily to the green fly, but a few years ago we failed to get it serviceable in destroying fly in Chrysanthemum blooms. Fumi-

gate them as we would, still they lived. We then concluded that it was possible there might be bad XL All as well as bad whisky. Red spider is an extremely difficult insect to kill if once established, but is it not quite possible, if careful watch for its first appearance is kept, that this destructive little creature may cause little trouble? Preventives are better than remedies.—C.

### Murmurs from the Garden.

Men, of course, often say queer things, and some of those who say very much more than they think have recently been saying the following:—"That, notwithstanding the drain made on our young men by circumstances attaching to the late war, the gardening profession is still suffering from plethora. That nowadays there is a disposition on the part of our modern journeyman to shun the excellent training ground of the nurseries. This, if true, is a great mistake, for better time could not be spent than a short period in a first-class nursery. Gardeners should be well up in the culture and nomenclature of many of the ornamental trees and shrubs which furnish our pleasure grounds but, alas! they are not. The nursery is certainly the place for this. That because the summer and autumn were unkindly to plants and men, the winter is to follow suit by being very severe. We have personally not very much faith in prophecies, especially when connected with material so fickle as the weather. That it is quite possible the Chrysanthemum won't make so much noise as usual this year, because, first, the season was not the best possible, and again because the fateful 3rd of September occasioned a few broken 'heads' also the succeeding hard frost injured not a few. That gardening is not worth the candle, because everyone who earnestly desires to get a 'plum' doesn't get one. Well, the getting, no doubt, is a serious enough matter, but it is keeping it, that troubles one.—H.

### Societies.

#### R.H.S., Scientific Committee, September 23rd.

Present: Dr. M. C. Cooke (in the chair); Rev. W. Wilks, Messrs. G. Massee, Saunders, Holmes, Douglas, Dr. Rendle, and Dr. Masters.

*Diseased Helianthus*.—Stems of *Helianthus* exhibited were rotting at the base, and dying off in great numbers. Externally there were, here and there, traces of white mould, but when cut down longitudinally the pith was found to be occupied by numerous sclerotia similar and perhaps identical with those found in Potato haulms and Tomato stems, and appear to be quite sufficient to account for the dying off. This Potato disease is fully described in Worthington Smith's "Diseases of Field Crops," p. 15, and the life-history of the sclerotium given, in which it is shown that the ultimate development is a small *Peziza*, there called *Peziza postuma*, but undoubtedly the same as had previously been described as *Peziza Libertiana*, and more recently called *Sclerotinia Libertiana*, and by Massee as *Sclerotinia sclerotiorum* (see Massee's "Plant Diseases," p. 150, fig. 32). It seems to be found indiscriminately upon plants of various kinds, but commonly on Potato and Tomato, Chrysanthemum, Cucumber, Turnips, and Sunflowers.—M. C. C.

*Pear disease*.—The Pears sent to the last meeting, cracked, shrivelled, and blackened by the attacks of *Fusicladium pyrinum*. In no case could I find any evidence of the presence of the *Entomosporium*, which produces similar results. It is noteworthy that, intermixed with the *Fusicladium*, were found profusely the hyaline, curved, and septate conidia of some species of *Fusarium*, which certainly bears no relationship to the *Fusicladium*, and would be a distinct parasite. This requires further investigation, since many of the species of *Fusarium* are destructive parasites, and this has every appearance of being a new and undescribed species.—M. C. C.

*Leaf-spot of Celery*.—The leaves of Celery exhibited were spotted with somewhat orbicular bleached spots, at first brownish, and then whitened towards the centre. Scattered over these spots are the minute black dots which represent the perithecia, enclosing the sporules. These are not so numerous as in most other species, and the sporules are long and thread-like, oozing out in a tendril in damp weather (35–40x1–2μ). It is the same species which occurs on the leaves of Parsley, and is known as *Septoria petroselinii* (Desm.). It occurs also in France, Belgium, Germany, Italy, and South America.—M. C. C.

A vote of thanks was voted to Dr. Cooke by acclamation.

*Abnormal Pear*.—Rev. W. Wilks showed an instance of a fleshy fruit-like growth resulting from a double flower. The end of the flower-stalk in these cases becomes fleshy internally, but externally bears leaves in successive whorls one above another, like so many ealyees. No true fruit or seed is formed. The condition is not uncommon.

*Clubbing in Cabbages*.—Mr. Massee pointed out that if the seed bed were free from the pest, the soil dressed with gas lime, and if the seedling plants can be got over the first three weeks of

their life free from attack, there is no danger of subsequent infection.

*Chlorosis of Apple and Other Trees.*—In reference to this subject, discussed at the last meeting, Mr. Gaut now sent twigs of Apple trees and of Raspberries from a garden in Yorkshire, together with samples of the soil taken at a depth of 9in and 18in respectively. It was suggested that the samples be sent to the analyst to determine whether or no they contain copper.

*China Asters.*—Specimens of these plants, showing the symptoms so commonly met with, were referred to Dr. Cooke for report, the supposition being that the condition was due to the Aster-worm, described and figured in the "Gardener's Chronicle" by the Rev. H. Friend.

*Spot in Grapes.*—From Derby came specimens of Muscats affected with this fungus, now too commonly met with. It is due to a species of *Glæosporium*, often noticed in our columns, and also in Viala's work on the diseases of the Vine. Destruction by fire of the affected berries, so far as possible, and the use of a fungicide spray next season, are the only remedies that can be suggested.

*Distorted Apples.*—Some distorted fruits were shown, whose small size and crippled appearance were attributed to imperfect fertilisation and a check to growth.

*Callas.*—Some specimens from Rougham Hall were exhibited, in which the leaves had failed to expand properly. This was supposed to be due to some arrest of growth, the reason for which could not be ascertained without knowing all the circumstances under which the plants were grown.

*Canada Rice.*—Mr. Douglas showed a specimen of this annual Canadian grass, whose seeds are used as an article of food. A fine clump may be seen at Kew.

*Begonias.*—Mr. S. Brown, of Edwinston House Gardens, Newark, sent male flowers of tuberous Begonias in which the anthers had been replaced by stigmas, and the upper surfaces of the petals were covered with imperfect ovules. Such changes are common in cultivated Begonias.

*Chrysanthemum Leucanthemum.*—Dr. Masters showed a specimen in which stalked flower-heads proceeded from the axils of the leaves all up the stalk.

*Sweet Pea.*—The same gentleman showed flowers of Lady Grisel Hamilton from his garden, in which the base of the standard was deeply divided into two rounded lobes; almost all the flowers on the plant were thus affected, and some few on other varieties, so that it seemed as if this formation was, or if selected might be, a precursor of a separate race.

*Griselinia littoralis.*—Mr. Burbidge sent from Dublin a specimen of this New Zealand shrub, with small, ovoid, berry-like fruits, which are very rarely produced.

*Diseased Melons.*—In reference to the supposed bacterial disease of Melons referred to at the former meeting, Mr. Willard now sent the following letter, which confirms his original statement:—"Acting on your suggestion, I have tested inoculation still further. Two plants were selected that had finished their fruit off satisfactorily, and to all appearance were remaining healthy. The first had a hard woody stem; the sap of a diseased plant was introduced by a scratch in the bark, the next day discoloration took place, in three days the disease could be seen, and in a week the plant succumbed. In the case of the other, which was somewhat more succulent, the inoculation was done on Monday morning, and the plant was practically dead on the following Friday, the disease going right through the stem, and seemed to cut off the supply of sap from the root. I may add, these two plants had thick, healthy green leaves, more so than usual for plants that finish their fruit quite up to ripeness. The house has not been shaded, and the plants have had abundance of air during the day with a little left on at night.—J. WILLARD, Holly Lodge Gardens, Highgate, N., September 22, 1902."

### Bristol Gardeners' Association.

The summer session of this association was concluded on Thursday evening last, under the chairmanship of Mr. Binfield. Mr. Garnish, Staple Hill, provided the paper, his subject being "Bulb Culture," with which he dealt in a practical way, advising potting early for Christmas blooming, such as Hyacinths, Tulips, and Narcissus, and at intervals for successional blooms. He added that our gardens could be made most gay and pleasing if planted with Narcissus, Tulips, and others, blooming as they did when flowers were so scarce. His paper was a very interesting one, and he was cordially thanked. Prizes for collections of Apples and Pears were awarded to (first) Mr. J. B. Brain (gardener, Mr. Atwell); (second) Mr. Bruce Coles (gardener, Mr. Lee); and (third) to Mr. J. Chetwood Aiken (gardener, Mr. Clarke), all three exhibits being exceptionally good. For three sections of honey the prizes went to Mr. A. Baker (gardener, Mr. Orchard), Mr. Mills Baker (gardener, Mr. Board), and Mr. Chas. Wills (gardener, Mr. Shewring), respectively. Certificates of merit were awarded to Mr. A. Baker (gardener, Mr. Orchard), for a basket of Peaches, and to Sir Herbert Ashman (gardener, Mr. Shorland) for two *Kochia scoparia*. A special certificate was recommended for Lady Cave (gardener, Mr. Poole, F.R.H.S.), for a good collection of Plums.

### National Dahlia Society, Sept. 23rd.

First Class Certificates awarded to the following New Cactus Dahlias:—Manxman, from Mrs. S. Mortimer; Mrs. Seagrave, Mrs. W. Cuthbertson, Charm, Minnie West, all from Mr. J. T. West; Princess, from Keynes, Williams, and Co.; Coronation, do.; H. F. Robertson, Mabel Tulloch, F. H. Chapman, from Messrs. J. Stredwick and Son; Decima, Ella, and Albion, from Messrs. J. Burrell and Co.; also Show Dahlia, A. M. Burnie, from Mrs. St. Pierre Harris; Pompon Meplisto, from Mr. C. Turner, and Imogene, do.; single Serita, from Messrs. J. Cheal and Sons.—J. F. HUDSON, Hon. Secretary.

### PLUM, RIVERS' PRIMATE.

This handsome kitchen Plum was raised at Sawbridgeworth, and received an Award of Merit on 11th of October, 1898.

Plum, Rivers' Primate.

In Messrs. Rivers' catalogue it is described thus: "Very large; skin, bright purplish red, with a bright bloom, thickly spotted with small dots; juicy; a freestone. Will hang on the tree until the middle, or end of October." The late Mr. T. Francis Rivers, the raiser, wrote to the *Journal of Horticulture* regarding this and other varieties, as follows: "This is a valuable Plum for market, and, like the Monarch, is also well adapted for drying. October is gradually being furnished with good Plums. For dessert we have Reine Claude de Bavay, Late Transparent, Grand Duke, Late Orange, and Coe's Golden Drop; and for the kitchen, Monarch, Primate, Wyedale, Late Orleans, and September Beauty."

### Meteorological Observations at Chiswick.

Taken in the Royal Horticultural Society's Gardens at Chiswick, height above sea level 24 feet.

The early mornings have been misty and cold, the days fine, bright and warm.

### Trade Catalogues Received.

H. Cannell & Sons, Swanley, Kent.—*Autumn Catalogue.*  
W. Fromow & Sons, Chiswick.—*Bulbs.*  
William Paul & Son, Waltham Cross, Herts.—(1) *Roses*; (2) *Hardy Trees and Shrubs, and Herbaceous Plants.*  
Perry's Hardy Plant Farm, Winchmore Hill, London, N.—*Bulbs.*  
André Schwartz, Rosarian, 238, Grand Rue de Montplaisir, Lyons.—*Roses.*  
L. Späth, Baumschulenweg, Berlin.—*Fruit Trees, Roses, Shrubs.*  
William Watson & Sons, Clontarf Nurseries, Dublin.—*Carnations.*

### Hardy Fruit Garden.

**GATHERING FRUIT.**—Another substantial addition may now be made to the quantity of fruit in store, completely clearing the trees of those varieties of Apples and Pears which should now have matured well. The latest may hang until they are more fully advanced towards ripening. Premature gathering is detrimental to their keeping in good condition for a lengthened period. They probably would not decay, but they are liable to shrivel, and gain no flavour. The late varieties, both of Apples and Pears, are of hardy texture, and will not suffer from a few slight frosts. With careful picking and storing a large percentage of the fruit will keep well, examining them occasionally for defective specimens, which remove. The early varieties now in store must be more frequently inspected, as being softer in texture they are more liable to decay.

**COB NUTS AND FILBERTS.**—On the nuts becoming quite ripe they are readily gathered from the trees or bushes. Before placing them, however, in store, it is necessary to thoroughly dry the husks. Lay the nuts thinly in a dry airy place under glass for some days, turning them over frequently. They may then be stored in a cool, dry room. After the leaves fall, suckers from old plants may be dug up, and planted to form fresh plantations.

**RENOVATING WALL TREES.**—After the clearance of fruit from the trees, no better opportunity can be chosen to examine thoroughly the branches and spurs of the various forms of fruit trees. Spurs may be elongated, and the branches too thickly placed. Elongated or distorted spurs are caused by the crowding of the branches. The removal of all branches that are nearer together than a foot is desirable now. The spurs may be gradually thinned out, and shortened as opportunity permits throughout the winter and early spring. Where quite a large number of branches require removal, it will be better not to attempt them all in one season, as too severe amputation is likely to be detrimental. Pare cuts smoothly. In the case of fan-shaped trees, a re-arrangement of the principal branches may be effected, and, in doing so, cut out those weak and exhausted.

**ROOT-PRUNING.**—Carrying out a judicious system of root-pruning is an excellent manner of bringing fruit trees into a bearing condition. The luxuriance which is fatal, is where trees make long and strong growths, form large leaves, and do not produce or properly perfect fruit spurs. The real cause usually lies at the roots; these, instead of being present in dense fibrous masses, are more in the nature of long and strong, thick roots, which have a greater tendency to grow straight downwards than in any other way. The object of root-pruning is to alter the character of these roots, which can be effected by shortening them, thus giving them a check, and inducing them to put forth their vigour in a greater number of smaller roots. When root-pruning is decided upon, it is wise not to carry it out too severely, therefore, in the majority of cases only operate on one side of a tree in any one season. A trench, not less than 3ft from the bole, should be excavated. The strong roots found should be cut smoothly at the side of the trench. Go down low enough to see whether there are any strong, descending roots. If so, one or more of these may be severed, leaving the ends perfectly smooth, not jagged or split, for by this care only can fibrous roots be expected to push. Where it is possible to lift the roots and place them horizontally, do so, as a more fruitful condition of the trees will ultimately be ensured if the roots can be induced to ramify and multiply near the surface. The lowest descending roots cannot be so readily raised, but the higher roots may. In filling in the soil again, which may consist of the staple material taken out, with the addition of some substantial loam, mixed with a little bonemeal and wood ashes, work it well round the roots, and make it firm. The fibrous roots found in the course of excavation should be carefully placed on one side, and laid out horizontally to their full extent. Mulch the surface with light, flaky manure.

**SOIL PREPARATION FOR FRUIT TREES.**—As the planting season is fast approaching it is necessary to prepare the proposed sites for planting trees and bushes. In all cases, deep cultivation should be practised, taking pains to thoroughly break up the soil to a good depth. With the exception of Gooseberries and Currants, Raspberries and Blackberries, manure should not be introduced, for rich soil induces Apples, Pears, Plums, and Cherries to make strong and unfruitful wood. In breaking up the soil do so to a depth of 2ft, and manage so as to keep the spits of soil in their same relative position, for it so happens that the best soil lies usually near the surface.

**STRAWBERRIES.**—A final planting of young, well rooted specimens should be made. These can be obtained from between the rows of established Strawberries, reserving promising young plants when clearing the beds of weeds and runners. Small plants, too, which have been rooted in special beds, will, with good treatment have become strong and abundantly furnished with roots, and should lift with compact balls of soil attached. Plant firmly in rows 2ft apart. All plants for forming new beds ought to be secured from good fruiting plants, as it is unsafe to use any from a fruitless source. Newly procured varieties of Strawberries are necessarily not furnished with soil to the roots. Spread out the fibres on small mounds of soil, and cover carefully so as to give them a good start.—EAST KENT.

### Fruit Forcing.

**CHERRY HOUSE.**—Where light, airy, and well-heated lean-to or three-quarter span-roofed houses are available, and these face the south, Cherries can be had with certainty early in April, and are then welcome additions to the dessert. The trees may be either in pots or planted out. By the first of these methods the trees can be removed as soon as the fruit is gathered and the wood sufficiently matured, to a sheltered, sunny situation outdoors, and the house is then at liberty for growing Cucumbers, Melons, or Tomatoes, which, from a remunerative point of view, are quite as good an investment as the Cherries. On the planting-out system finer fruit is had, the growths being trained 9 to 12in from the glass, but it is necessary to have the roof lights moveable, and the house can only be used for the Cherries. If it is intended to plant any trees it should be seen to as soon as the leaves commence falling. Cherries thrive best in calcareous gravelly or sandy soils, but for trees under glass the compost is preferably rather strong, especially when the loam contains a free admixture of calcareous or flinty particles. Turfy loam, with a sixth of old mortar rubbish, and a similar proportion of road scrapings, will grow Cherries well. If the soil be light, add a fourth of dry marl, dried and powdered fine. Provide a drain of 3 or 4in pipes, having due fall and sure outlet. There should also be 9in depth of brickbats or rubble for drainage, the roughest at the bottom, with the material diminishing in size upwards to that of road metal, and on this place 3in thickness of old mortar rubbish, being careful to have it free from pieces of wood. A depth of 24in of border is ample, and 6ft width will meet the requirements of trees grown under glass. The compost should be placed together firmly. Early Rivers, Governor Wood, Black Tartarian, and Elton are excellent varieties, both for size and quality. The lights having been removed, they need not be replaced for six or eight weeks, the old surface soil being removed without injury to the roots, and fresh compost supplied, that above named answering with the addition of a fourth of well-decayed manure.

**TREES IN POTS** required to be drifted into larger sizes should be attended to at once, and those not needing such treatment may be turned out of pots, removing a few inches from the base, cutting back the roots, supplying fresh loam, adding old mortar rubbish, if not calcareous, with a fourth of decayed manure, and providing good drainage. Remove the surface soil in other cases as well as the last named, and supply fresh loam duly enriched, making quite firm. Afford a good watering, and place the trees in a position where they can have abundance of air.

**VINES—EARLIEST FORCED IN POTS.**—For affording ripe Grapes at the end of March or early in April, well-ripened canes from cut-backs started early in the year are most suitable, they being as stout as walking sticks, short-jointed, brown and hard, with eyes like nuts. They should now be at rest, have had the laterals cut off close, and the cane shortened to the length required, 6 to 8ft. The Vines do best in a lean-to or three-quarter span-roof house, and preferably with a pit along the front of 3 or 4ft depth for holding leaves, there being a pathway at the back, and a trellis for training the growths at a foot distance from the glass. A good start is assured if bottom heat can be provided, a bed of fermenting material two parts, two parts leaves and one part stable litter, affording a mild, lasting heat. Place loose brick pillars, 9in square, about 2½ft apart, for the pots to stand on, and so high that the rims of the pots are level with the top of the fermenting bed. The material must be brought off loosely about the pots in the first instance, and not have a temperature of more than 65 or 70deg at the commencement. Vines that have ripened early, been pruned, and had six weeks' rest, may be started at once for supplying fresh ripe thin-skinned Grapes as early in the year as possible, which cannot well be effected before March, and to effect this the earliest varieties, as White Frontignan, Foster's Seedling, Black Hamburgh, and Madresfield Court should be chosen. The temperature at starting should be 55deg by artificial means, and when the buds show signs of breaking it may gradually be increased to 65deg. The canes should be slung in a horizontal position, or lower at their extremities than the base, to induce them to push their buds evenly throughout the length of the canes, syringing them two or three times a day, also the paths and

walls. Sufficient water must be given at the roots to keep the soil moderately moist whilst the Vines are inactive, and only evenly so after they start, but when in free growth they need liberal supplies of nourishing food in liquid form, preferably alternating with supplies of water.

**EARLY FORCED PLANTED-OUT VINES.**—The Vines intended to be started early in December for supplying Grapes in late April or early in May should be pruned at once, so as to allow them some weeks' rest before starting. The Vines must be thoroughly washed with a tepid soapy solution, merely removing any loose bark without interfering with the live wood or bark, as harbour of this kind is favourable to the hibernation of red spider, mealy bug, and thrips, following with an approved insecticide. Where the roots have the run of outside borders it will be advisable to prepare some fermenting material for placing on that part after the Vines are started, the border in the meantime being protected from heavy rains by spare lights. Two-thirds of Oak or Beech leaves to one of fresh stable litter thrown into a heap and turned over once or twice, moistening if necessary, will afford a durable heat and source of nutrition. These materials will require renewal from time to time, and if this cannot be effected, it is better to dispense with any at the beginning, only such protection of leaves and litter must be provided as to prevent the soil becoming frozen in the severest weather. Thoroughly cleanse the house, everything being put into proper order, and keep as cool as consistent with the safety of the Vines.—ST. ALBANS.

### THE COLLARET DAHLIA.

A new type of Dahlia has come into existence. It has been named "the collaret" form, and first was brought to notice by Messrs. H. Cannell and Sons, Swanley, Kent, from whom we kindly received the small illustration of a flower of this race. This new class possesses, round the ordinary yellow disc, a series of stalked appendices of a collaret form, producing a great ornamental effect. The engraving gives a good idea of its nature. The colours are somewhat limited at present, but in the course of another season or so, the variation of tints will be very much increased, and the formation of the remarkable collaret growth more accentuated. The original plants have already been awarded Gold Medals and Certificates at various important exhibitions. President Viger is the best-known variety, with large, circular flowers, on stiff footstalks of a reddish carmine colour, with a smaller collar of pure white florets; very distinct and effective. Joseph Goujon is another collaret, producing flowers a trifle larger than the above, of a bright reddish scarlet, the collar florets being yellow, slightly marked red. Either plants or seeds of these can be secured, and as there may be a future for this race, it is probable that many growers will obtain plants to form a beginning with them.

### TRADE NOTES.

#### "Bitter Oil" Insecticide.

If it were not for the attacks of vegetable parasites and of insect depredators, the gardener's task would be inestimably lightened. But these destroyers or hinderers of his labour most emphatically exist. It is, therefore, advisable to employ and to test the efficacy of insecticides such as those prepared by responsible firms who have devoted studious attention to the subject. It is in order to bring to notice the bitter-oil insecticide that we pen this paragraph. The oil itself we are about to test, and have received from the Hull Chemical Works, Limited, a half-gallon tin for the purpose. Their "plant-cleanser" is also sent to us in the same size of tin. A friend of ours with whom we communicated regarding the use and effect of this insecticide has been kind enough to forward the following letter:—"On Friday last I visited a fruit-grower in my neighbourhood to inspect particularly some Apple trees. Two trees when in full blossom were dressed with Bitter-Oil for the purpose of preventing ravages of the codlin moth. We examined the trees carefully, and couldn't find any diseased fruit, and I send you a sample of the fruit gathered on Friday. The grower informed me that last year these two trees had heavy crops, but not only were the Apples absolutely unsaleable, but couldn't be used in his own house, and were given to the pigs. He also drew my attention to the clean and healthy appearance of the trees compared with those which had not been dressed." It only remains for us meanwhile to add that the Apples were safely received, and that they were perfectly clean, juicy, and healthy samples.

\* \* All correspondence relating to editorial matters should be directed to "THE EDITOR," 12, Mitre Court Chambers, Fleet Street London, E.C. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense.

**DAHLIA, F. W. WELLESLEY (J. Allen).**—This new Cactus variety is one of the finest seen during the current season. In our issue of August 21, on page 182, we described thus: "A rich crimson Cactus variety of large size, and beautifully narrow fluted petals; good in form." An Award of Merit was bestowed by the R.H.S. The raiser's name and address is Mr. H. Shoesmith, Claremont Nursery, Woking, Surrey.

**RANUNCULUSES FROM SEED (Amateur).**—Keep the seeds you have saved in a dry cool place. Early in spring mix a compost of strong loam and leaf mould, and fill some boxes or seed pans, well drained, very nearly full; sift a portion of it and place a thin layer over the rough compost, and press it very gently down. Mix the seed with some fine soil, rubbing the seed and the soil well together till the seeds are separated from each other. Sow this mixture upon the soil in the boxes or shallow pans; press it down level, and with a fine sieve sift some of the compost

Collaret Dahlia, President Viger.

evenly over it the thickness of a shilling: then with a watering pot, the nozzle of which has the finest holes, give a gentle watering. Place the seed pans under glass in a cold frame or pit, or in front of a low wall facing the east, and contrive a covering or shelter of some kind to protect them from heavy showers. Whenever the soil appears dry give water with the fine-rosed water pot, and in strong sunshine place a shade over them till the seedlings appear above ground and have attained a leaf or two to each plant. Search well about where the boxes or seed pans stand, and even lift them up and examine under them to see if any slugs or woodlice have crept there to hide themselves. Continue this attention till the leaves begin to decay and then cease watering, but keep the plants clear of weeds. When the leaves are all decayed and winter is approaching place the pans of seedlings in some very cool place where no rain can fall upon them, and keep them there till spring. About the middle of April bring them out and give them a good watering. Sift over the soil a thin layer of fresh compost, and repeat the care and attention with regard to watering, looking after insects, and keeping clear of weeds as in the previous season. This second year, when the leaves fall and the plants are at rest, the tubers will have attained some size. They should now be taken out of the soil, and the surest way to accomplish this without losing any roots is to sift the upper part of the soil through a fine sieve, fine enough to catch even the smallest roots. Store them away in a cool dry room, and in the spring plant them out.

**ANONA, PURPLE INSIDE (J. D. A.).**—We can assign no reason other than you may have been feeding the plants more liberally than usual. Doubtless the colouring has no material ill effect.

**GROWING PELARGONIUMS PLANTED OUT IN HOUSES FOR CUT BLOOM (Ninga).**—Beyond making the soil firm we do not know of any other method of keeping the wood within bounds, this securing, with due space for development and stopping irregular growths, sturdy growth in the plants and fine trusses of bloom. It is usual to cut the plants hard back after they have produced their wealth of bloom in the spring and early summer, so as to secure a good plant by about September, when they will bloom in a light house with a temperature of 50deg to 55deg by day and the atmosphere always on the dry side. Young plants should be stopped once or twice to encourage a compact habit, care being always taken to pinch to a joint at which is situated a growing bud. The plants are probably best from cuttings inserted the previous autumn or early in spring, and the plants obtained should be grown on throughout the summer, and not allowed to flower until, say, about September. A light, airy house or pit with a warm, fairly dry, atmosphere, will be the best situation from the time the plants are rooted until about midsummer, when they should be placed on a bed of coal ashes in the open air, or in a shallow pit with the lights removed. This plan is adopted in order that the growth may be short-jointed and become well ripened by autumn.

**MARIE LOUISE VIOLET LEAVES TURNING YELLOW (J. P.).**—The plants are suffering from a deficiency of nitrogenous matter, and possibly also of iron, being in the condition known as chlorosis, and is not unusual to the Neapolitan varieties on limestone soils. The plants appear to have been very loosely planted, the soil falling away from the roots without handling. It was sweet and good, but contained a considerable amount of lime. Had the soil been firmer the plants would have made a sturdier growth and larger leaves, though this would have been an advantage in helping to retain colour, yet the poverty of the soil is clearly accountable for the foliage being so pale. Another season we should manure the ground heavily, and if you can command it work in some leaf mould, making the ground quite firm before planting, and in summer mulch the whole border with short about half-spent manure. It would also be advisable to give a few sprinklings of soot, say a peck per rod, which would improve the colour of the leaves as well as otherwise contribute to the health of the plants. As you are about to place the plants in frames it would be desirable to plant in good rich soil, they doing capitally with leaf mould mixed with it, and the plants may be watered with soot water, but keeping it off the foliage and flower buds. If you would like to try the effect of sulphate of iron, you may sprinkle it on the soil before planting in the frame at the rate of a quarter-ounce per square yard, finely powdered before application. It should be kept off the plants.

**NAMES OF PLANTS.**—*Correspondents whose queries are unanswered in the present issue are respectfully requested to consult the following number.* (J. C.).—1, *Helianthus giganteus*; 2, *Helianthus rigidus*; 3, *Echinops sphærocephalus*; 4, *Geranium sanguineum*; 5, *Clematis integrifolia*. (J. M.).—1, *Cassia corymbosa*; 2, probably *Ficus repens variegata*, but we are unable to identify such a mere scrap with certainty; 3, *Adiantum trapeziforme* var. *Catharinæ*; 4, *Adiantum Paccottii*; 5, *Codiaeum (Croton) pictum* var.; 6, *Codiaeum*, Mrs. Swan. (Journeyman).—A Liliaceous plant, but not identified from the piece sent. (W. Brown).—*Mimulus cardinalis*, a capital plant for spring flowering in pots, or for beds in the summer. It is easily cultivated. (J. B.).—1, *Betula urticifolia*; 2, *Betula nigra*; 3, *Betula alba lentæ*. (F. N.).—1, *Begonia margaritacea*; 2, *B. sanguinea*; 3, *Hoya imperialis*.

**NAMES OF FRUITS.**—*Correspondents whose queries are unanswered in the present issue are respectfully requested to consult the following number.* (J. G.).—1, *Duchesse d'Angoulême*; 2, *Capsheaf*; 3, *Deux Sœurs*; 4, *Calebasse Grosse*; 5, *Marie Louise d'Uccle*; 6, *Beurré Superfin*. (J. Petts).—26, *Brabant Bellefleur*; 30, *Cellini Pippin*; 31, *Emperor Alexander*; 32, *Stoke Pippin*.

## Covent Garden Market.—October 1st.

## Nature Studies.

And Nature, the old nurse, took  
The child upon her knee,  
Saying, "Here is a story book  
Thy Father hath written for thee.  
"Come, wander with me," she said,  
"In regions yet untrod,  
And read what is still unread  
In the manuscripts of God."  
And he wandered away and away  
With Nature, the dear old nurse,  
Who sang to him night and day  
The rhymes of the Universe.

We believe Longfellow wrote these lines, having in his mind that great Swiss savant Agaseing, who, with the inquiring spirit that ever seeks for truth, penetrated deep into the hidden things of Nature, and yet, with the humility of a little child, considered that his knowledge was but of the slightest. So it is with the wisest. Their very wisdom shows them the depth of their own ignorance. It is only the ignorant that are confidently certain about anything.

We are only just beginning to realise the difficulties that beset the path of those who would educate the masses.

Allowed that our manners are faulty, and that we concede at once, the next difficulty is that the masses just get a crumb of knowledge and then turn round and challenge the whole world of learning. We cannot compel them to a longer course, and they do not get enough to make them value more. They will strive possibly after out of the way "subjects" that are good in themselves, but of no practical value in the daily life of the would-be learner. The text book system seems to be the main thing. Outline work instead of deep research. That is because the work of a lifetime is compressed into the compulsory school attendance. When school is finished, the books are shut, and in the majority of instances the mind lies fallow and lazy.

But at last our educational authorities appear to be waking up; at any rate, to the needs of country children, and we welcome with satisfaction any move in the right direction. Now, this course of teaching that comes under the head of "Nature Studies" seems to us to be a likely plan to awaken in dormant minds love of the country and of country pursuits, and by so doing may tend to wean lads (and lasses too) from the ever growing desire to migrate to the towns.

The first step is the acquisition of a garden plot. That entails the purchase of tools. The tools, rent of ground, and manures (farmyard and chemical) are met by the Government grant; the managers finding seeds. There is also an Aid grant to fall back upon. We are struck with the fact that in the case of one school mentioned the gardening class is taken by the mistress. When the weather does not permit of outdoor work, the children have conversational lessons, write essays on the work done and about to be done, and study diagrams and pictures.

From a well kept garden to a well tilled farm is but a step, and a child who has noted the growth of vegetable life in a garden, and practically studied the best methods to ensure the vitality of the plant, will have a lively interest in the crops of the farm. The work at first is bound to be rudimentary; but it is at the early stages it must be made of interest. Object lessons are now made most delightful in elementary schools, and this work touches on objects that surround the child in its home. Insect life presents a wide field. There are insects in the various stages easily reared, and their development watched. Let them collect the objects themselves, remarking where and when found, and the teacher must do his part by explaining why certain forms of insect life are injurious or otherwise to animal and plant life. Fortunately here the teacher has immense assistance from coloured drawings and diagrams provided by the late Miss Ormerod.

Then we pass on to animal life, hedge and wood life, and it will often be found that intelligent children have gained much information for themselves, which only needs to be put into some sort of form by the teacher. We see that for Standards IV. and V. it is suggested that the child's attention should be directed to no less than thirty\* subjects; but we ourselves think the range is rather a wide one. All the subjects are most excellent, but as the average child only stays in a standard one year there would be fifteen subjects for each year. Of course, it is not as if much time could be allotted to each of the fifteen subjects. We fancy the limit is two hours per week. We will pick out the subjects on which, if we were teachers, we should be inclined to dwell:—Food of plants; common garden weeds, desirable and undesirable; grasses (and here we should suggest the value of a good collection from, say, a firm like Suttons or Carter); insects injurious to flowers, vegetables, farm crops; animal pests; bird pests; "the farmer's friend," as comprised in animals, birds, earthworms. Here surely are subjects for most useful lessons, better, we think, than courses of tonic sol fa and—but we dare not go further, or all the schoolmasters of Great Britain will be down upon us.

For Standards VI., VII., it is suggested that the formation of soils be the first subject, then the classification of the same, and the working of ditto, or, rather, how the working affects the plant life. Land surveying follows this course, and here the chain plays a prominent part. Nowadays so much is piece work that it is well if the labourer can check his own measurement instead of leaving it, as is now the case, in the hands of outsiders. There would be fewer disputes between master and man.

We cannot go seriatim through all the admirable sug-

gestions for the Nature Study course found in pages of the "Schoolmaster." We are only afraid the task as it stands at present is almost too big to be grappled with. That we fully agree with the moving spirit goes without saying, and it is always best to try to attain a high ideal. We think something might be done for the girls in the poultry line, for it is to them the care of fowls is generally committed, either on the small farm or in their cottage homes. We are certain of one thing, that someone needs teaching the art of dressing for market. There is such an advantage to be gained by those who send their fowls to either the big centres or to private customers ready for the oven.

We constantly see fowls on the table which fall far short of what they should be. We do not mean they are not fat, but they have not been dressed and trussed into good form. The young girls do not like the work, and would rather not learn. They are not taught soon enough. We do not go so far as to say this is a subject for the Elementary School "marm" to handle, but someone should do it. The fine art of female milking is very much on the wane, and the sister art of calf rearing.

Here we are with a sad shrinkage in our live stock, in a great measure because there is the difficulty of rearing. The old fashioned farmers' wives were as proud of their hand reared calves as the men were of their crops. Depend upon it, for all the ridicule thrown upon the movement, we must have women back as co-workers in the agricultural sphere—we were going to say "field," but that might have been taken too literally. There are, indeed, some field operations which are really best performed by women; but, after all, they can, if willing, find work enough and to spare in and about the homestead.

### Work on the Home Farm.

Strong winds have been rather trying to both loaders and stackers, but they brought the corn into fine condition, and stacks are rising in every direction. Here all is in stack except rakings, and a corner or two which are of little value, and will be put in the heap with them. Raking stacks, at any rate large ones, is somewhat of a novelty since binders came in, but this year they are very bulky. Threshing is general, and will be for the sake of straw, as well as money. Oats are reported to yield well, and Wheat fairly so. Barley has not yet been put to the test. Farmers are not paring their Barley stacks, neither are they thatching them at all freely. This points to early threshing. It is to be hoped they will allow the sweating period to pass before commencing. Present-day maltsters are generally prepared to take a big lot of Barley at Michaelmas if it is in condition, but not otherwise.

As we anticipated, the price of Oats has tempted farmers, and rather large quantities have been marketed. A dealer tells us that he bought 500 quarters at one country market, that the supply is already exceeding the demand, and he expects to buy at 16s. next week.

The reared calves are grazing the old seed pasture and look well. They come into the covered yard at night, and have an allowance of corn cake.

Scarce as hands are, we saw a man thatching a Wheat stack yesterday. The farmer (occupier of about 300 acres) told us he had twenty-one men at work, including a gardener, blacksmith, joiner and a saddler. Harvest did not take him long.

Potatoes will soon be ready to lift, but thatching has to be finished, and while that work is proceeding there will be a chance to put the cultivator through the Wheat stubbles. Not much can be done, but once over will be better than nothing, and they are very clean to begin with.

Lea intended for Wheat must be ploughed at once. Many thin pieces of seeds were broken up before harvest. These may be ploughed later, but as soon as convenient. The untouched seeds should be ploughed first, so as to get a stale furrow. Where Oats are in favour, no doubt these fields will be retained and sown with them, as the pasturage may be made good use of until Martinmas, especially where few roots are grown.

The sheep are finishing the Cabbages on the land where they grew. The next break is Thousand-headed Kale, after which it will be a case of common Turnips or nothing. A small allowance of Clover is given them in the racks, and  $\frac{1}{4}$  lb per head of lamb food. This is a small allowance, but lamb food is dear, and Clover plentiful. The Thousand-heads are hardly ripe enough, neither will the Turnips be when we get to them, so the dry Clover will be all the more necessary to keep the sheep free from indigestion and scour. Good horse corn is still an expensive item, and may be so for many weeks yet. New Oats are not very good feeding though they are comparatively cheap. Maize is very dear, and will be until the new crop comes in. Split Beans, Maize, and bran in equal proportions remain the best available food for the arduous autumn campaign of three months' work in two months' time.

\* This, of course, is optional.

## BARRS' GOLD MEDAL DAFFODILS

Have received Twelve Highest Awards, 1902, including **TWO GOLD MEDALS**  
Descriptive Catalogue of all the finest sorts in cultivation free.

## BARRS' GOLD MEDAL TULIPS

Have received **FIVE GOLD MEDALS** from the Royal National Tulip Society; **SILVER CUPS** at the Great Temple Flower Shows, 1900 and 1901, and **GOLD MEDAL** 1902.  
Descriptive Catalogue of the finest kinds for pot culture and for forcing, and for beds and borders outdoors, free.

## Journal of Horticulture.

THURSDAY, OCTOBER 9, 1902.

### The Sweet-Sop.

SOME years ago, while staying with a friend in Yorkshire, he received a large case of Orchids and other plants from Singapore, among which was a bundle of cuttings, all planted together in a large tin case, each cutting about 7in long, without name or any clue by which to recognise them. Some had rooted, it is true, and were just beginning to grow; but for the most part they were in a wretched condition, and looked very unhealthy. As I have always had a fancy for any new or unknown plants, and my friend evidently did not set much store by his "leafless plants," as he called them, I begged they might be given to me, and on my request being granted I took them home next day, and carefully planted in separate pots as many as I thought had any chance of living, putting them into a new hotbed, and keeping them moist and shaded for a week or two. The few which remained I stuck into the bark-bed of the stove, where I had been working, pushing them into the tan behind a large Pine.

I took immense pains with my cuttings in the frame, tending them with the greatest care—with too much, in fact; for, do what I would, after they had rooted slightly and begun, as I hoped, to grow, all died off one after another. I moved two or three into a drier atmosphere, but with no better result; and the upshot of the matter was I lost them all, much to my vexation.

Two months after this, having occasion to renew some of the bark in the stove, I was moving the Pines for that purpose, when lo! behind one of them was a plant which I recognised directly as one of the very cuttings I had stuck in there ten weeks before. Yes, there it was, sure enough, growing like a

**READERS** are requested to send notices of Gardening Appointments or Notes of Horticultural Interest, intimations of Meetings, Queries, and all Articles for Publication, officially to "**THE EDITOR**," at **12, Mitre Court Chambers, Fleet Street, London, E.C.**, and to no other person and to no other address.

Willow, with shoots 6in or 7in long, and looking as healthy as ever I wish to see any plant, the sole survivor of my three-dozen ill-fated slips!

The next thing to be considered was what should I do with it? Move it I must; but with the fate of its companions still fresh in my memory I hesitated about taking it up. However, at last I got a large pot, drained it well, and filled it about half full of good rich garden soil, mixed with a little leaf mould. I then carefully dug out the plant, putting it into the pot, tan and all, taking particular care not to injure or disturb the roots, and kept it close and warm for a few days until I saw that it was settled, giving very little water. Directly it began to grow I placed it in the hottest part of the stove, where it could have plenty of sun. It grew rapidly, filling the pot with roots in the course of the summer, and forming a nice bushy tree. I kept it dry all the winter, repotting it early in spring, when it started afresh, growing with great vigour, and in August it bore three large greenish flowers.

Up to this time I had not the faintest idea what my tree was; but one day, while I was showing my plants to a gentleman who had recently returned from India, he exclaimed, "Why, you have got a Sweet-Sop tree!" and so it was. My cutting had turned out to be the *Anona squamosa*, or, as it is commonly called abroad, the Sweet-Sop.

After this I had much trouble with it, as the fruit would neither grow nor ripen, dropping off soon after the flower; and for more than two years, although I obtained plenty of blossom, I did not get anything else. At last, however, I hit upon the plan of growing the trees (for by this time I had several), in smaller pots and poorer soil, and I then had the satisfaction of seeing the fruit grow and ripen.

When ripe the fruit becomes of a yellowish colour, and is covered over with large scales on a thick rind. It is about the size of a small Pine Apple, and when cut open is not unlike one in appearance, only instead of having a firm flesh, it is filled with a delicious pulp, tasting uncommonly like Strawberries, or Raspberries and cream, with the creamy taste predominating. Even in this country, when well ripened, the flavour is delightful, and I have little doubt but that in its own it is far better. The fragrance of the pulp, too, is remarkable, being like rosewater, or rather sweeter—more like the scent of an old-fashioned Cabbage Rose.

There are several other species of *Anona*, cultivated for the sake of their fruit, particularly *A. Cherimolia* and *A. muricata*. They are all natives of the tropical parts of Asia, Africa, and America; but, as I know little about them, I shall confine my remarks to the Sweet-Sop (*A. squamosa*). This tree, even in its own country, never grows above 7ft or 8ft high, and here it never exceeds the size of a bush. To grow it for fruit it should be planted in a 13in pot, and kept plunged up to the rim in a bark bed, as it will not thrive without plenty of bottom heat. The soil should be a good ordinary garden loam, not stiff, and by no means rich, as if the soil is too good the tree will flower but not fruit. Like the Mango, the Sweet-Sop delights in a very high temperature, with plenty of moisture when growing, and requires little air. Indeed, it is best grown with the Mango and Mangosteen, and treated in every respect as these trees are, excepting that the fruit requires thinning as soon as it is fairly set, leaving no more than ten or a dozen on each tree. When ripe it should be cut, although it will hang for some weeks by removing the trees into a rather cooler atmosphere. Like many other fruits, it is best when gathered fresh from the tree.

At dessert the Sweet-Sop should be divided into two or four parts lengthwise, never across, a very sharp knife being needed to sever the thick rind. This must, however, be done at table, and not before dinner, or the fine aroma will be lost. When first opened one fruit will perceptibly scent the whole room, and for this reason, when practicable, the Sweet-Sop should always be served along with the Durion, its delightful perfume completely overpowering the disagreeable scent of that fruit.

One point must be borne in mind, which is, that the flavour of the Sweet-Sop depends entirely upon the fruit

being thoroughly ripened in all the sun possible. For this very reason the taste often varies, sometimes being all that could be wished, and at others quite tame and insipid, the least shade when ripening being quite fatal to flavour.

The Sweet-Sop grows very readily from either seeds or cuttings, but when raised from seed it is shy of flowering, and, therefore, in practice, the latter is the best mode of propagating it. Care must, however, be taken not to give the cuttings too much water, as they are exceedingly liable to damp off until well established. They will not bear fruit for two years.

The Sweet-Sop is rarely attacked by insects, and is not, I believe, subject to any disease; it is easily fruited if grown in a small pot, and kept constantly in a high temperature; and, when the exquisite flavour of the fruit and its delightful perfume are considered, I think I shall not be far out if I express the opinion that ere long this luscious fruit will be found in every tropical fruit stove.—J. H.

## The Lachenalia.

The season is now far advanced for the planting and potting of those bulbous plants intended to flower next spring or early summer, whether for the embellishment of the garden out of doors or the conservatory or greenhouse. One of the prettiest and most indispensable for the latter purpose is certainly the *Lachenalia*. As it is one of the prettiest, so also is it one of the easiest to grow successfully.

The *Lachenalia* is a native of South Africa, and comes into flower at the end of April, continuing to bloom well into June. The flowers are produced on leafless stems, in a manner similar to the English Bluebell (*Scilla nutans*), only the scapes are not quite so long. The colour of the flowers varies from rich gold in the varieties *taurica* and *Nelsoni*, to bright green, red, and yellow in tricolor. Each bulb will produce from two to four flowers, according to its size and quality.

*Nelsoni* is the handsomest variety of all, and where the first desideratum is a brilliant show of flowers in abundance, there only tricolor and *Nelsoni* need be grown. Bulbs of the tricolor species are abundant, and can be bought at small cost. *Nelsoni* bulbs are scarce, and command higher prices.

The compost that suits them best is loam two parts, leaf mould and decayed manure one part, river sand one part, the whole well mixed and passed through a half-inch sieve. They should be potted into 5in pots. If the bulbs are of good size, five bulbs in a pot will be sufficient; but if only of second quality seven or eight will not be too many. Bulbs of various sizes should never be planted together in one pot, but selected; the largest by themselves, the medium sized and small the same.

The bulbs should be covered with the soil to the depth of half an inch, and the soil should be pressed rather firmly over the bulbs. So soon as the potting is over, the pots should be placed in a cold pit on a floor of ashes, on which a little quicklime has been sprinkled to prevent worms getting into the pots. The soil in the pots should now receive a good soaking of water, and no water must afterwards be given until the young growth appears on the surface, and this will be in about a month or six weeks after potting. The days will now be shorter and colder, and the plants must be removed to another pit or some other structure from which frost is excluded; but the young plants should not at any time be subjected to artificial heat, and should during the winter occupy a position near the glass, where they may enjoy abundance of cool air, protected only from frost.

Growth will make good progress during the autumn and winter, and the plants should be encouraged by careful watering to form strong plants by the spring. The flower scapes will appear during the month of April or May, and a little artificial manure sparingly applied at this time renders useful help in developing the size and brilliancy of the flowers. Liquid manure from the farmyard is the best to use, and should be applied in a weak state, and not oftener than twice or three times a week.

The best position for them to develop their flowers in is a shelf in a greenhouse close to the glass, where they can have abundance of air. So soon as the flowers are fully developed, manure water must be withheld, and the plants arranged in a cool and airy place in the conservatory, where their pretty and brilliant blooms will help to make this house gay and interesting for a matter of five or six weeks. After the flowers are over, water should be given more sparingly until the foliage decays, when the pots may be placed on their sides in a cool place until the bulbs are again wanted for potting in August.—OWEN THOMAS.

### Forms of Orchid Flowers.

"One of the characters which especially impresses a student of the great Orchid family," writes Mr. Lewis Castle in his interesting shilling book on Orchids, "is the surprising range of floral variation, yet within such definite limits that an Orchid flower is usually easily recognised. In the majority we find three outer divisions—the sepals—and within these three, other divisions alternate with the sepals, two—the petals—being more or less similar to them in form, though frequently differing in colour, while the lower one (in a few cases this is uppermost)—the labellum or lip—is strangely metamorphosed, sometimes excessively large, at others very small, of the most peculiar forms, mimicking insects and birds, or extraordinarily and indescribably

### Forms of Orchid Flowers.

| 1. <i>Oncidium raniferum</i> (Frog Orchid).                            | 6. <i>Cynoches ventricosum</i> (Swan Orchid). |
| 2. <i>Peristeria elata</i> (Spirito Santo of Panama), the Dove Orchid. | 7. <i>Oncidium pulvinatum</i> .               |
| 3. <i>Prescottia stachyodes</i> .                                      | 8. <i>Bolbophyllum barbigerum</i> .           |
| 4. <i>Gongora quinquenervis</i> .                                      | 9. <i>Catasetum viride</i> .                  |
| 5. <i>Cirrhaea tristis</i> .   | 10. <i>Peristeria cerina</i> .                |

grotesque. It is this which gives the prevailing character to Orchid flowers, and it is an important organ.

"In the centre of the flower we find no stamens or pistil, such as we are familiar with in other flowers, but a compound body, the column (gynostegium), which faces the labellum, and bears on that surface a hollow glutinous cavity—the stigma—and has at the summit a box-like depression, covered with a lid, the anther-case (clinandrium), in which are situated the pollen-masses (pollinia), consisting of grains of pollen, connected into various forms by a web-like or glutinous substance. Beneath the flower is the ovary, termed from its position inferior, and this, when cut across, is found to be one-celled, with three rows of seeds extending down the inner surface of the walls. They are mostly very minute, very numerous, and covered with a loose skin (testa).

"These are the prevailing characters of the family. There are, however, some exceptional cases, and some details which will be referred to presently. For instance, an Orchid flower is usually very irregular, owing to the development of the labellum;

yet in a few genera, as the *Thelymitra*, *Hexisea*, and *Paxtonia*, the parts of the flowers are nearly all equal.

"In these the lip is the same size as the petals and sepals, and could scarcely be thought to be the same organ as the lip in the *Ladies' Slipper* (*Cypripedium*). Through these regular flowered Orchids, Lindley traced the relationship to the *Iris* family, especially to *Sisyrinchium*; and we obtain a chain of forms, varying in the modification their flowers have undergone, from these to the strangest and most mechanical flowers imaginable."

### The Week's Cultural Notes.

The weather must be closely watched now, and the treatment of the various sections of Orchids varied accordingly. In dull, wet weather it is a mistake to damp down as usual the first thing in the morning. Better by far to wait until later in the day, while on some days it will not be necessary to damp at all. Anyone who has had a little experience knows by the feeling on entering a house whether it is right or not, and will damp or not accordingly. When a little fire heat has been kept in the pipes, and a good circulation of air thereby allowed, damping will be necessary more frequently than when no heat is used.

But an hour or two of drying never hurts any Orchid at this time of year, while a too abundant supply of moisture is harmful to many, especially should the outside temperature be low, and prevent free admission of fresh air. In the mildest cases it leads to flabby and weak foliage; while in the worst, mould, spot, and other attendant diseases difficult to check are set up. Those growers who, for the sake of a little trouble or a trifling outlay in fuel, leave their fire out entirely at this time of year, little think what a short-sighted policy they pursue, for without a little warmth in the pipes it is unreasonable to expect a proper circulation of air.

*Cattleya Harrisoniae* is a lovely plant, but one very often badly treated by growers. The flowers are very lasting, and what is more to the point, are very freely produced, but none the less even weak plants are allowed to carry them until they fade, and this often in a draughty conservatory or room where the atmosphere is quite uncongenial to them. A more weakening régime, or one more calculated to injure the plants, can hardly be imagined, yet this is what goes on in scores of places yearly. Were the flowers removed after a reasonable time and the plants returned to a situation where the atmosphere would replenish the energies spent upon flowering, all would be well.

And this reminds me of a fact often lost sight of, that when *Cattleyas* once fall into a really bad condition they can never be again restored to health. A newly imported piece may come home with shrivelled stems owing to the long drying it has had, and in the presence of heat and moisture will soon plump up and regain strength; but once let a plant that has been grown for years under glass shrivel up badly owing to wrong treatment, and not the most skilful of Orchid growers will in one case out of a score bring the plant back to health. Keep well aired, then, is my advice to growers of this useful species, and do not be led, because of the lovely show the plants are making, to keep them at work too long, and thereby imperil their chance of future usefulness, or even life.—H. R. R.

## The Perennial Lathyrus.

So far, the pure white form of *Lathyrus latifolius* has monopolised the attention of amateur and professional alike, but surely the deep pink and delicately blush-tinted and striped varieties deserve some attention. It may not be generally known that varieties embracing so many shades of colour exist, and undoubtedly, when they are as well put before the flower-loving public as the white *Lathyrus latifolius* has been, they will attain as great a meed of praise.

To ensure good results they require generous cultivation, and to have them in really fine form will amply repay for indoor culture. When this can be afforded, crops of flowers may be obtained some six weeks before their wealth of bloom enlivens the gardens. If planted indoors, the back wall of a cool greenhouse suits them admirably. A good trench to the depth of 3ft should be taken out, the bottom deeply broken up with a fork, and the trench refilled with a compost of good loam, a sprinkling of  $\frac{1}{2}$  in bones, with a liberal addition of charred garden refuse. Vigorous syringing with soot water will keep in check the troublesome red spider. Copious douchings overhead with weak liquid manure during active growth not only help to keep this in check, but assist the plants considerably.

Like its blood relation, the Sweet Pea, the season of flowering may be prolonged by keeping the seed pods removed, and I have found a slight rest and pruning helpful in stimulating fresh growth, with the invariable sequence of a good crop of useful flowers in the late autumn.

The plants can be increased by cuttings taken near the base,

but unfortunately they resent too much cutting when the growth is young. As screens for covering unsightly places, or forming arches and bowers, they are extremely useful, whilst their hardiness and their increasing vigour when once planted compensates to some degree their lack of perfume, a quality that makes *Lathyrus odoratus*, or Sweet Pea, such an universal favourite. Let us hope that ere long the assiduous cultivators who have taken it in hand will give us new varieties embracing in one form the good qualities of both.—E. J. LOVE, E. Dereham.

## Arbor Days.

(Concluded from page 306.)

The question is always asked whether forests will pay. I can only say that Herr Gustav Wegener, Councillor of Forests, of Coburg, in advocating a term of eighty years for the cutting of Pine forests, calculates to receive from medium soil a yearly revenue of from 3 to 5 per cent. on the value of the land. With Beech forests it would be about the same; but the timber of Oaks, requiring from 120 to 160 years before being felled, is constantly rising in value, and the State is in future only going to plant Oak for timber, and not for firewood.

I have always advocated Arbor Days since, in 1882, I passed through the west of the United States, and noticed the alteration they have made in the appearance of these formerly treeless regions. Whether these are or can be introduced with advantage in Great Britain I am unable to say; but if so they might within a short time become a most enjoyable holiday for the whole neighbourhood. I presume there are not many schools with an area of five acres—the smallest area recommended in the United States. But if there is any available land for planting in any neighbourhood the children of the school or schools, although taking part in the planting, need not prevent grown-up persons from planting also, and thus make it a general holiday, as sketched by Mr. H. S. Sterling Morton, who established Arbor Days in the United States, when he said in 1887 at the State University of Nebraska, "Ordinary holidays are retrospective in honour of something good or great, but Arbor Day is not like other holidays; it sketches outlines, establishes the useful and beautiful of ages yet to come, etches upon our prairies and plains gigantic groves and towering forests of waving trees, whose beauty will compel the admiration and gratitude of men and women yet unborn. It is the sole holiday of the human family which looks forwards and not backward."

Cannot horticultural societies offer premiums to the men who properly plant the greatest number of trees during the next three years, or at any District Arbor Day? And would not such Arbor Days soon be welcomed with as much zest and enjoyment as they are now in most of the United States (and here in South Australia), even where there is no great scarcity of trees in the neighbourhood? Each year larger and larger numbers interested in previous plantations, which may be near or adjoining that to be planted, will meet there and enjoy both this meeting with old school-fellows, and also be pleased with the growth of the trees they had formerly assisted in planting.

To encourage the best growth, it seems to me not out of place now to refer to manuring. Only quite lately Belgium, Denmark, and Germany have commenced to fertilise the land upon which forests are to be planted, or even established forests. Formerly nursery plots for forest trees were usually manured with dung, but in 1869 Peruvian guano was first applied, and soon afterwards other commercial manures. It was not, however, till 1880 that this became at all general. Photographs taken of young trees of the same age have convinced me that the increased number and size of the roots produced in fertilised nurseries gives them a better chance when transplanted, and Dr. Smets states in his pamphlet, "La Culture du Pin Sylvestre en Campine," that "if you sow Pines, as so often is done, in a nursery with impoverished soil, you can only obtain sickly plants, which have little chance of success."

M. Martinet also says: "It is a wrong idea that young seedlings should be acclimatised and made hardier, so that, if intended for poor soil, they may be satisfied with the local conditions. Pines one or two years old take out of the soil from 24lb to 28lb of potash, 20lb to 24lb of phosphoric acid, 60lb to 64lb of lime, 16lb to 20lb of magnesia, and 56lb to 64lb of nitrogen per acre, so that it is an undoubted fact

that after the removal of the seedlings from the seed-beds the soil is so impoverished that mere stable dung and green manuring is not sufficient to again raise strong seedlings from beds which must of necessity be used again and again."

Dr. Giersberg, of Berlin, from whom I take the particulars as to the manuring, recommends for nurseries the use of from 640lb to 800lb of Thomas' phosphate and the same quantity of kainit, the latter to be applied long before the sowing of the seeds for green manuring. The crop should be ploughed in when in full bloom and the first pods are formed. Without green manuring, nitrate of soda should be applied between the rows in one or two doses, according to the quantity which seems necessary, from 80lb to 160lb. Dr. Giersberg also thinks it advisable to put a portion of the Thomas' phosphate into the subsoil, and the rest, before or after sowing or planting, into or on the surface soil. In nurseries on peaty soils in Denmark and in Schleswig-Holstein the ground is dug at least 13in deep in autumn, and then receives 640lb of kainit and 400lb of Thomas' phosphate of 17 per cent. per acre.

In May 200lb of Lupines are sown and ploughed under as before mentioned, with 1,200lb kainit and 800lb Thomas' phosphate again applied. This may seem too much, but when actually 3,200lb of each were applied the seedlings thrived well, and were certainly not damaged. Frequently up to 160lb of nitrate of soda is given later on, and even a second dose.

Belgium seems to be in advance of all other countries in the use of large quantities of fertilisers for forests. Sixteen to 18in is the usual depth of ploughing there before planting, and if a subsoil plough can be used 2ft 4in to 2ft 6in is not unusual. Large tracts of waste lands are thus planted and fertilised, and to do so at the smallest expense Rye and other crops are raised for some years between the rows of the young trees. Green manuring mostly consists of Lupines, which will penetrate even hard and pebbly soils to a depth of 3ft, and thus permit the moisture to rise, by means of the openings left by their dead roots, for the benefit of the trees.

Liming is also used, or in very sandy soil marling is preferable. Potash and phosphoric acid are added to improve the surface soil, which, when thus treated, is expected to keep the trees in good health and growth for ten to fifteen years, after which time the roots are likely to find sufficient nourishment in the deeper subsoil. Where green manuring with Peas was used on a sandy soil of the eighth class, a good crop gave no less than 180lb of nitrogen per acre, equal to about 1,150lb of nitrate of soda. Professor Dr. Goetting used in one instance 640lb of Thomas' phosphate and also of kainit; in another twice as much; and Dr. Dalgas, of the Association for Planting Danish Heath-lands, actually recommends five to ten times as much potash, and four to six times as much phosphoric acid.

That it will pay to use fertilisers for forests can hardly be doubted. The experiments, at least, are very encouraging, but more time must elapse to decide whether any further fertilisers are required, whenever, for instance, Pines show at a certain age a stoppage in their growth. Professor Dr. Wohltmann, after many experiments, declares that in most instances large stores of mineral fertilisers are to be found in the deeper subsoils, and thinks more manuring unnecessary. It is ascertained that 1lb of nitrogen is sufficient to produce from 125lb to 200lb of dry wood, 1lb of potash up to 3,300lb, and 1lb of phosphoric acid up to 5,000lb.

Whenever fertilisers are given to single seedlings or to larger trees, they should not be used in larger quantities, nor without being well mixed with the soil. From 1oz to 2oz of Thomas' phosphate,  $\frac{1}{2}$ oz to 1oz of 40 per cent. kainit, and  $\frac{1}{2}$ oz to 1oz of nitrate of soda may be sufficient, the last to be repeated the following year. In Eberswalde, in a forest of seventy-year-old Pines in poor condition, 800lb of both Thomas' phosphate and kainit and 160lb nitrate of soda per acre were used. At Hadamar, Oaks eighty years old have been felled, and Pines sown amongst the stumps with the same quantity of fertilisers. The stumps showed shoots as much as 6ft long, while on unmanured land these were only 2ft to 3ft long. Fifteen-year-old Pines in miserable condition, only 1ft 8in high, and making only 2in shoots annually, were three years ago mulched with horse-dung. In the very first year they showed a fine green colour, and the average annual shoots made since are more than a foot long. Mulching with Potato haulm or other material gave not quite so good a result. The annual shoots averaged 8in; the nourishing constituents in the dung caused, therefore, the growth of the extra 4in.—F. E. H. W. KRICHAUFF (in "Journal of the Royal Horticultural Society.")

# NOTES & NOTICES

## Appointment.

Mr. Alfred Clark, late foreman under Mr. F. G. Small, of Ashton Hall Gardens, as head gardener at Melbourne Hall, Melbourne, Derbyshire, an estate of Earl Cowper's.

## Beckenham Gardeners.

An interesting syllabus of meetings and lectures for the coming winter has been arranged by the members of the Beckenham Horticultural Society. This society possesses a horticultural library of 300 volumes, and nine evenings are specially set aside that members may foregather among the books and discuss them. Applicants should be sent to Mr. Mark Webster, librarian, Beckenham.

## Scotch Carnations.

How wonderfully late Carnations are this season with us in the north. Plants are full of bloom still, and no end of buds that, alas! shall never be able to expand into lovely flowers. I have never seen even such good doers as Asphodel, Sadek, Mephisto, and others, so fine, and some of the newer kinds are retaining the good opinion previously formed of their qualities. At the beginning of the season, and especially under glass, the gloriously brilliant Sir R. W. Griffiths was just a little disappointing, as were also some others; but of late, in the open, it has come out in all its beauty. In its home in Kelso, in Messrs. Laing and Mather's nurseries, it was last week, producing the most lovely orange-scarlet blooms in great profusion. Our layers have done splendidly, too, and it may well be noted as an indispensable border Carnation.—B.

## Flower-adorned Business Premises.

"When at Bath some weeks ago," writes "E. D. T." to the "City Press," "I noticed what an effective show was made by a little floral decoration outside one of the banks in that city. I found on inquiry that it was the banking firm over which our own Lord Mayor presides that sets this excellent example. I inquired as I passed how much it cost to thus enliven the premises all the year round (for in winter, evergreen shrubs take the place of flowers), and I was struck by the comparative smallness of the sum. The City proper, and London generally, would be much improved if more attention were paid thus to 'appearances.' The attempt on the piazza of the Royal Exchange compares most unfavourably with the instance I quote at Bath. There is another consideration to name in this connection, and that is the help it would be to our nurserymen and florists in the suburbs, if more regard were had to making dingy business premises look a little more cheerful by floral and evergreen decoration."

## Reading Gardeners' Association.

The first fortnightly meeting of the winter session was recently held in the Abbey Hall, and was well attended, Mr. G. Stanton presiding. The subjects for the evening were: "Melons in Pots," and "Stoking." The former was introduced in a very practical manner by Mr. E. F. Exler, The Gardens, East Thorpe, Reading, under the following headings: Soils, watering, syringing, stopping, ventilation, shading, insects, disease, varieties, &c. The latter subject was taken up by Mr. E. Fry, The Gardens, Greenlands, Reading, who made some forcible remarks on the stokehole, boilers, and fuel. The discussions were well sustained. Great interest was created in an exhibit of Cactus Dahlias staged by Mr. C. P. Cretchley, The Gardens, The Honeys, Twyford. The varieties were Lord Roberts, Rosine, Vesta, J. W. Wilkinson, W. Jowett, J. Weir Fife, Cornucopia, Mrs. E. Mawley, and Mrs. Carter Page. Mr. H. House, The Gardens, Oakfield, Reading, staged a collection of Apples and Pears, and Mr. G. Durrant, The Gardens, Preston Lodge, Reading, specimens of the various types of Dahlias. Seven new members were elected. The subject for the meeting to be held on October 13, is "Flowering Trees and Shrubs," illustrated by limelight pictures, by Mr G. Gordon, V.M.H., editor of "The Gardeners' Magazine."

## Trial of Potato Diggers.

The great trial of Potato diggers, under the auspices of the Royal Lancashire Agricultural Society, whose president, the Right Hon. the Earl of Derby, K.G., G.C.B., offered very valuable prizes (first prize £20, second prize £10), was held at Carr Hall Farm, Burscough, yesterday, at 11 o'clock prompt. Nine machines, representing the best makers of Potato diggers, competed, and the trials are looked to by agriculturists and growers of Potatoes in the North of England with special interest.

## Tree within a Tree.

There has been found at High Wycombe a curious illustration of growth under abnormal conditions. A quantity of Canadian Birch timber arrived at one of the chair factories there, and in the centre of one piece, 3in. in thickness, there was found a young Birch tree, 2½in in diameter, which had escaped the saw. It had enjoyed an independent growth, and it is supposed, reports the "Sun," that years ago a seed fell into a sapling, which forced its way up through the trunk of its parent. The hollow was completely filled a distance of several yards. This curiosity is to be preserved.

## Horticultural Meetings in London.

Meetings of floriculturists in London were held on Tuesday last as follows:—The Committees of the Royal Horticultural Society, 12 to 1 o'clock, in the Drill Hall of the London Scottish Volunteers; National Rose Society's General Purposes Committee, at 3 p.m., in the rooms of the Horticultural Club, to consider the programme for 1903, &c.; National Sweet Pea Society, at 4 p.m., in the Hotel Windsor, to consider the alteration of Rule 7; and in the Royal Aquarium the Floral Committee of the National Chrysanthemum Society met after the judging at the Society's early autumn exhibition, was completed.

## Horticulture at Brotton.

At the request of several miner-gardeners and allotment holders in Brotton, Yorks, a course of five lectures on "Horticulture" has been arranged, and will be delivered in the Institute by Mr. Alfred Gaut, of the Yorkshire College, Leeds. Mr. Gaut has lectured at other centres in the Cleveland district, and the instruction gained by those who attended has proved of value to many who cultivate the soil, either as a hobby or for profit. The arrangements have been made in connection with the North Riding County Council technical instruction scheme, and Mr. A. P. Maddison, Brotton stationmaster, is the local secretary.

## Echoes from Hamilton.

October has opened here with good prospects. The air is dry and cold, but seasonable, and we see more of the sun than has been our fortune for some time. Those among us who declared that on the reappearance of the sun, it would be meet to have its photo taken for "Auld Lang Syne," can have every opportunity for doing so now. Harvesting of all kinds has become now general. What a comparison with ordinary years; quite a month behind. Nor do the cereals look as if they were even yet quite in approval of the application of the sickle. They appear so wan and tinged with an unnatural greenish hue, so different to that healthy golden colour generally associated with the advent of autumn. But our soil is naturally cold and unkindly; a cold clay and consequently retentive of moisture. The forests themselves also seem to share in the sickly, yellow-greenish tinge, and do not present themselves in their wonted garbs of golden red. The leaves, already, it is true, come rustling down, but they seem not to have passed through those interesting—and shall we also say instructive?—stages at this period of their existence. September was a phenomenal month in many respects. It furnished us with a very severe and destructive gale, also one night of severe frost. Wet, of course, and sunless days were largely in evidence, but, perhaps, upon the whole, with all its defects, it was a decided improvement on the two or three months preceding it. Chrysanthemums, though naturally not so good as usual, are nevertheless in some cases looking exceptionally well. They promise, both at Camphill and the Botanic Gardens, Glasgow, to be very fine, and already there is a fine display to the fore. The good weather of the last few days has wonderfully revived bedding plants, and at present our gardens are looking not quite so desolate as they appeared some weeks ago. Hawthorn berries are in abundance, and so are blackbirds.—D. C.

#### Housing the Plants.

Unsettled and treacherous weather is now our portion, and it is not wise to trust good plants to the buffeting of wind and rain, and the probability of sharp autumn frosts. The latter may not harm late plants, but those with prominent buds are more susceptible to injury. In addition to these reasons for housing, is the important one of advancing the buds so that the blooms may open at the time expected of them, whether for exhibition or other purposes. Immediately any plants show colour in the buds it is distinctly injurious to the buds to allow the plants outdoors longer, for the colder nights and heavy dews cause a check which may not, however, be evident for some time.

It is assumed that the structure in which the plants are placed is thoroughly clean, and a light position can be accorded them. Before taking in the plants, go over them, and pick off any decayed leaves; cut out any weak or superfluous shoots, rubbing out side shoots forming or extending in the axils of the main leaves. Pull out weeds on the surface of soil in pots, and wash the latter clean, dealing with the under surface as well as the sides.

Attention next must be given the foliage, which is liable to mildew attacks, especially on the under sides. The remedy for mildew consists in the use of Veltha, or of a mixture of flowers of sulphur and water. Lay each plant on its side in some convenient place, and syringe the under sides of the leaves with the mixture. A large mat placed on the ground, and the plant laid upon it, will answer well in preventing the foliage being splashed with dirt. Mildew is a fine, white deposition on the leaves, and is the result of the growth of a fungus. If a good deposition of fine sulphur can be made to cover it, it will be destroyed.

A light, airy house, and one that can be heated if necessary is best for Chrysanthemums. Many growers, however, must utilise the space they have at command. It is not advisable to have the heads of the plants too near the glass, as the extremes of heat and moisture are there great. This may cause injury to the blooms as they advance, they then being very susceptible to adverse influences. Plants producing exhibition blooms may have their heads about 18 in or 2 ft from the roof. The pots should not stand too closely together. It is better that air and light should reach well among them, so as to preserve the foliage until the last.

Groups of plants to give decorative display may stand more closely, but they are no worse for extra space if it can be afforded. Specimen plants must stand singly. In arranging a group with a background, place the tallest plants in the rear, gradually sloping towards the front, where the dwarfiest must be placed. The shape of such a group may be oblong, square, or semicircular. Such groups are best constructed when the plants come into bloom, as a tasteful combination can be formed with the help of other plants—Ferns and foliage plants. For a time, after first housing, it will be noticed that there is no progress, and the wants of the plants are few. Plenty of ventilation is essential.

Feeding may continue with all the plants from the time the buds show until the blooms are well advanced, when it should cease, clear water only being given. Disbudding is another item which requires attention, especially from the later plants and those producing the flowers on terminal shoots. Remove dead foliage from stems as necessary, and also take the opportunity of affording more space by removing any plants as they get past their best.—E. D.

#### The Collection at Draycot House, Chippenham.

The present is a time of much speculation as to the coming prospects among Chrysanthemum growers, and especially by those who number among the large body of exhibitors. The name of Bible has been a familiar one among successful exhibitors for a long time, not only since he has held his present important charge, but at an earlier period. Draycot Gardens has during the past two decades possessed reputations of a varied order, but in Chrysanthemum fame it has only taken up its new rôle since Mr. Bible has taken over the cares of its destiny. A recent visit paid revealed one eloquent fact, namely, that he is an extreme enthusiast, endowed with wonderful energy, and possessing a memory much to be envied. With all these high attributes it is only to be expected that not only Chrysanthemums are in good hands, but that other sections of the garden and its crops are similarly well done and cared for. The kitchen gardens, lawns, woodland walks, herbaceous borders, and glass departments are all severally bearing the mark of a generous employer—which the Prince Hatzfeldt undoubtedly is—and a gardener worthy of his name and calling.

For the production of large flowers some eleven hundred plants are grown, and among these many of the better novelties of the year may be found. Mr. Bible is enabled to grow sufficient of the newer ones to prove for himself their true merits, the time of stopping, and the best buds for producing large and well coloured flowers. He places, and rightly, too, a large value on depth of colour, apart from mere size in his blooms, and as the shows calling for his patronage extend over a somewhat wide period, he necessarily has to treat his plants with these objects and dates well in view. Thus, while some were at the time of my visit fast developing their buds, others were outdoors peacefully awaiting their turn. They are drafted inside in batches as their purpose instruct. Japanese and incurved sections only are grown, and though in numbers the former preponderate, the last-named are, if anything, the greater favourites, and they embrace a wide range of variety old and new.

The fruit houses at Draycot, some of which are of modern times, are very well adapted to the flowering of Chrysanthemums, and for the present they are allowed to enjoy all available light without shade or other roof obstruction. The forward buds display wonderful vigour and colour, and their future promises well.

Among novelties of the season may be mentioned Mrs. Thomas Pockett, Mrs. H. Emmerson, and General Hutton, of Australian origin, and the complete set sent out by Mr. Godfrey, all of which display great vigour of stem and leaf, and which is expected will be a distinct gain in bright colours. Older varieties are legion, but among them Ernest Bettisworth, W. R. Church, J. J. Thorneycroft, Mafeking Hero, E. Molyneux (good), Mrs. J. Lewis, Kimberley, Madame Carnot, Mrs. Mease, G. J. Warren, The Princess, Loveliness, Lily Mountford, Nellie Pockett, W. R. Barrett, Mons. L. Remy, Calvat's Sun, Sir George White, Mrs. Barkley (extra fine), Miss Elsie Fulton, Mrs. Coombes (good), H. J. Jones, and J. R. Upton.

The newer incurved number among them Mrs. F. Judson, Mrs. C. Crooks, William Higgs, Mrs. Neville, and George Hunt; others, such as Duchess of Fife, Mrs. H. J. Jones, Mrs. Murray, Globe d'Or, the Princess of Wales family, Dome d'Or, Ada Owen, Baron Hirsch (deep coloured), The Colonel, Rose Owen, Mrs. R. C. Kingston, C. H. Curtis, and Queen of England are excellent in every respect.

Disease is not absent, though its presence does not give cause for much alarm, for the rust spots are not yet abundant, and, as in other years, it is only certain kinds that seem liable to its attack. As might be expected, efforts have not been wanting for its suppression; a prescription of Mr. Bible's own has been brought to bear upon them with the aid of the syringe for some time past. Mystery still hangs about the disease despite the fact that anti-rusts and other fungus-destroying remedies are claimed to do all that is needed.

Though the season has been such a sunless one, maturity of the Chrysanthemum does not appear to be an absent quality, the stems displaying the pleasant brown tint, leaves leathery, and the buds swelling up with a freedom that gives occasion for genuine hope. Despite the multitudinous duties, and the vast area that has to be traversed over parkland and garden Mr. Bible finds time to attend personally to every detail of his Chrysanthemums.—S. Trowbridge.

## Lilies of the World.

(Continued from page 238.)

**CHINESE LILIES (GENUS LILIUM).**—Of these there are some twenty-five species known at present, but it is expected now that China is being opened up this number will be greatly added to. Very few of the twenty-five species are yet in commerce, but soon will be, and if they bear out the reports of collectors, they will form valuable additions to our garden plants. Lily amateurs are anticipating great things from this comparatively new Lily source, and from what we know leads us to anticipate there will be no disappointment.

**L. BROWNI.**—This is a plant with a history, beyond that of almost any other Lily I know of in cultivation. Some fifty or sixty years ago a Belgian one day was wandering about the now world-famed nursery of Mr. Charles Turner, Slough, England, and accidentally discovered flowering in a pot a Lily he had not before seen, and bought the same for 21s. from the proprietor of the nursery in question, who could give no history as to how the plant came into the nursery, it being part of the stock he found when becoming proprietor of Brown's business, as it was at that time called. It appears there were two brothers Brown, original proprietors. One became a missionary and went to the Far East, and the supposition is this was part of a consignment of Lilies, &c., sent home by the missionary Brown from China, all of which appear to have perished from neglect except this one, which would not follow its companions. The Belgian, whose name is not recorded, increased the plant and sent it out under its present name (Browni) in compliment to Mr. Brown. From this one Lily bulb sprung the entire stock of this Lily, now well known commercially in Europe, &c. From descriptions of recent finds of Lilies in China, I should in no way be surprised to learn that this beautiful Lily is one of them. I am thus particular, inasmuch as Japan has been named as the home of Browni, and the Japanese under this name send annually to Europe and America *L. odorum*. Under the name *L. Browni* it is somewhat in the same way, but quite different. *L. Browni* has long, pure white flowers of great substance, measuring some 10in in length. Outside, the flower is rich chocolate-brown, height 3ft to 5ft. *L. odorum* will be found fully described under Japanese Lilies.

**L. Henryi**, named after Dr. Henry, a gentleman in the Chinese Customs, Szemas, Tonkin, who sent bulbs to Kew as a new species of Lily. For its introduction into commerce we are, however, indebted to the enterprise of a Yokohama merchant, who, at great expense, went to Hong Kong, and from thence sent a Chinaman to collect the Lily in its native habitat, no doubt with the assistance of Dr. Henry. I had an offer in Hong Kong of the same assistance, but I said the man who first risked his money in the enterprise was the man to reap the harvest. When in Hong Kong, I heard of two collectors out from England to gather in the spoils of the Celestials. One I traced up the Yangtse, sent by Veitch, Limited, London, and no doubt under the auspices of Dr. Henry, if the Boxers did not have his head, returned home with much spoil of the land. The other was sent out by Sanders and Co., St. Albans, on a secret mission. Of him it might be said he came and went, leaving no footprints on the sands of time. When he passed through Hong Kong all was quiet at the time. How far he went into the unknown land in search of spoil I have seen no report, neither as to whether the Boxers left his head on his shoulders. I have noticed that some writers describe *L. Henryi* as a form of *L. speciosum*. I could not endorse this. I considered its nearest relative is *L. tigrinum*. *L. Henryi* has beautiful, soft, orange-yellow flowers, with as many as twenty on a stem when the plant is established and strong. Its culture is one of the easiest, and I may say its future is ensured; height, 6ft.

These two Chinese Lilies named are of the easiest culture, and those new species from the same country, which may soon be in commerce, from the flattering descriptions which precede them of their exquisite beauty and easy culture, we Lily amateurs may well look forward to a great treat, and I am sure South Africa will find a place for most of them in her rapidly developing gardens, now that it is found that the Cape Peninsula has the finest climate in the world for the growth of flowers.—PETER BARR, V.M.H.

## Needs of Fruit Trees.

(Continued from page 108.)

Respecting the need of fertilisers for orchards, Professor Voorhees says, it is argued by many that fruit growing is quite similar to growing timber trees; that the question of soil exhaustion is not a matter of very great importance provided the soil is well cultivated, and that all soils contain sufficient quantities of the food elements to insure the relatively small available supply required from year to year. It is admitted that on soils of good mechanical condition, well drained and cultivated, which are naturally adapted for fruit as well as other crops, because well supplied with the essential constituents—nitrogen, phosphoric acid, potash, and lime—the exhaustion arising from the continuous removal of crops will not become apparent for a long time, but it should be emphasised that it is only upon soils which possess these characteristics that the growth of fruit, even poor fruit, can be continued for any considerable period without the application of manures.

### Different Crops Require Different Food.

It is obvious that such specific results as have been obtained concerning the needs of general garden crops cannot be applied with any degree of accuracy to fruit crops, particularly the larger fruits, as Pears, Apples, and Plums, because these differ from vegetables—first, in their habit of growth; second, in the character of the produce; and third, in their relation to soil exhaustion.

In the first place, garden crops as a rule require but one year for the entire processes of vegetation and maturation. For fruit crops, with but few exceptions, the purely vegetative processes continue for at least three years, and with many kinds much longer; while after the fruit bearing period begins, the vegetative processes do not cease, but are coincident with the growth and ripening of the fruit.

In the second place, the product of the fruit harvest differ very materially in its character from that of ordinary garden crops, which mature their products and die in one season, because a whole season is required for its growth and development; that is, it is necessary that there shall be constant transfer of the nutritive juices from the tree to the fruit throughout the entire growing season, while the growth for each succeeding year of both tree and fruit is dependent upon the nutrition acquired and stored up in buds and branches, as well as upon that which may be derived from the soil.

In the third place, the relation of fruit growing to soil exhaustion is very different from that in general crop gardening, because in orchards there is an annual demand for specific kinds and proportions of soil constituents; it is really a continuous cropping of the same kind; there is no opportunity, as in the case of ordinary garden crops, to correct the tendency to exhaustion by a frequent change of crop, or the frequent growth of those which require different kinds and amounts of plant-food constituents.

### Principles Regulating Growth.

In studying methods of manuring orchards, it must be admitted that the general principles which apply to fruits apply quite as well to vegetables; that is, the essential constituents of manures must be the same. A fruit tree will not make normal growth in a soil destitute of nitrogen. That nitrogen encourages leaf-growth is a recognised fact, and since trees grow by means of leaf and root, its presence is required in the soil in order to promote the growth and extend the life of the tree. It is very evident, too, that potash is an essential constituent in the growth of fruits, not only because it constitutes a large proportion of the ash of the wood of the Apple, Pear, Cherry, and Plum, and more than 50 per cent. of the ash of fruit, but because it forms the base of the well-known fruit acids, and in order to nourish a tree properly as well as to ensure proper ripening, phosphoric acid is also very necessary. It is also a matter of common observation that, in the production of stone fruits

particularly, lime is an important constituent. Its function seems to be to strengthen the stems and woody portion of the trees, to shorten the period of growth, and to hasten the time of ripening. Fruit trees growing on soils rich in lime usually show a stocky, steady, vigorous growth, and the fruit ripens well; while those on soils which contain but little lime, particularly the clays, appear to have an extended period of growth, the result of which is that the wood does not mature and the fruit does not ripen properly.

Nitrogen is particularly efficacious in promoting growth. In fact, the amount of growth and the colour of foliage are reliable guides for the application of nitrogen. When mature or bearing trees make a foot or more of growth upon all shoots, and when the leaves are of good size and dark green coloured, the soil probably has enough nitrogen. A free application to such soils of the element nitrogen might do more harm than good in promoting growth at the expense of fruit.

#### Tillage an Advantage.

In general it is better to supply nitrogen by good cultivation, which assists nitrification in the soil. If the trees do not make sufficient growth and are yellowish in foliage, good cultivation begun early and repeated very frequently in connection with the use of potash and phosphoric acid, will usually correct it.

Potash is generally the most important ingredient to be applied directly to orchards, particularly after the trees have reached mature age. The store of available potash in the soil is much increased by the thorough tillage which has already been recommended, but in fruit-bearing orchards potash should also be supplied in some commercial form, as sulphate or muriate of potash.

In general phosphoric acid is probably less important in fruit production than potash, although it throws the tree into fruit quicker, and has a most beneficial influence on the growth of the wood and leaves. The best form in which it may be applied to trees is probably by bonedust, and half and quarter-inch bones. The coarser the bones the heavier should the dressing be.

The amounts of manure to be applied depend upon the character of the soils, the kind of fruit, and the age and vigour of the trees.—J. J. WILLIS, Harpenden.

## Insects as Garden Adornments.

A little while ago, taking his morning stroll round, a gentleman remarked to his gardener, "I can't think how it is, John, that there seem so few butterflies about the garden now." To this John replied, "It's because we don't grow the old-fashioned flowers, they don't care for these new sorts from abroad." I doubt whether the old man was right on this point, for the perfume of many exotic species is highly attractive both to butterflies and moths. But if he was thinking about the food of the caterpillars, hardly any occur in gardens or orchards, except those of the common white kinds.

With regard to this present season, owing to the wet and stormy weather of early summer, butterfly life has suffered generally throughout our islands, hence the numbers resorting to garden flowers have been below the average in 1902. Recent experiments have been made with a view to the introduction of various ornamental species of butterflies into London parks and gardens, but they are inclined to make themselves at home, and of course they offer a great temptation to juvenile hunters. Stragglers of the Vanessa tribe, such as the red admiral and small tortoiseshell, occasionally appear upon flowers in London's open spaces, it is true. But the commonest butterfly we see is the small white (*Pieris Rapæ*) which breeds in many London gardens, living as caterpillar upon all sorts of plants. Some of the large white (*P. Brassicæ*) also take excursions amongst the flowers, having fed upon Cabbages or kindred vegetables on kitchen garden ground near.

We all welcome the "children of the sun" to our gardens, be they small or large that visit us; some of our friends, though admiring the large, handsome species, think it is quite delightful to see the small blues and skippers moving gracefully from flower to flower. Much depends upon locality—a garden near heaths, extensive fields and old chalk pits, or patches of waste land where nettles and thistles are surrounded by a thick undergrowth, is one likely to have butterfly visitors. Certain woodland species seldom leave the copses for gardens, though the Rev. J. G. Wood sets down the high brown fritillary on his list of insect foes, because the caterpillar was stated to have been found on garden Violets. Its occurrence must be exceptional, and it

A View of the Gardener's House at Drumlanrig.

would not seriously damage the plants. Fritillaries, about which I wrote recently in these pages, seldom fly into gardens, though they are welcome visitors, beautiful, and speedy on the wing. Probably the likeliest to appear is the silver-washed fritillary, somewhat of a rover. Even the splendid purple emperor has been known to visit a garden, his fine sense of smell, we suppose, informing him of the presence of over-ripe or fallen fruit, since their juices are to him a source of enjoyment.

Conspicuous, if not handsome, is the black-veined white species, with semi-transparent wings, and well-defined blackish or brown markings. This butterfly is said to be fond of the Broad Bean bloom, and, being sociable, it sometimes occurs in parties upon wild flowers in patches, such as Great Ox-eye Daisy. It is rather scarce and local in our island, which is quite as well, so we seldom come upon it about gardens now. Likely, this insect was once commoner, for an old Chelsea entomologist records having seen the caterpillar plentiful upon Hawthorn in hedges amongst suburban market gardens. On the Continent there are many localities where the gregarious caterpillars are abundant, and cause serious injury to the fruit crops some years. They resemble our lackey caterpillars in living under a web at first, becoming full grown in May. Occasionally a clouded yellow butterfly (*Culias edusa*) is tempted into some garden near Clover and Lucerne fields on sunny autumn days. This is handsome and easily recognised, even at a distance, but it is dexterous in avoiding the net.

Place of honour amongst our garden beautifiers belongs to the strong-winged, many-hued butterflies of the Vanessa tribe. Brave and brisk is the red admiral, *V. Atalanta*. His Latin name tells of his speed, and he will fearlessly alight upon a flower close to our feet. This is one of the few butterflies that take excursions after dark, and sometimes it comes to the sugar spread by entomologists. "Admirable" some say the name was originally, and indeed it is to be admired. Both sides of the wings are lovely, the under having a charming combination of grey, pink, and brown. This butterfly appears in gardens as a pioneer of spring. Having hybernated, the summer brood is out during August, and specimens occur till October, if the weather keeps fine. Still more familiar to us is the small tortoiseshell (*V. Urticæ*), which on sunny days visits some gardens by the dozen. It is one of those butterflies which seem to be attached to the residences of man. Specimens often hibernate in sheds, conservatories, and dwelling-houses. The caterpillars live upon the stinging nettle. Not unusually we observe them by parties of hundreds about June. Then we have a large tortoiseshell amongst our native species, but *V. polychloros* is rather local, and unknown in some counties. I have observed individuals visiting gardens in Kent and Hertfordshire. It might be a commoner butterfly, since the females are prolific, depositing each about four hundred eggs, the caterpillars being sociable, and living with us on Elm, Poplar, or Willow. But they may occur on Cherry and Pear, for in France the caterpillars have been so abundant in orchards as to strip these trees.

The peacock butterfly, akin to the preceding, prefers roadsides and open fields to gardens, but it has one favourite amongst cultivated species, and that is the Michaelmas Daisy. When settled upon a flower with closed wings, this butterfly looks almost black. Its beautiful eyes are hidden from view. That capricious dame, the painted lady, which is numerous some years and quite invisible others, is a possible visitor in September or October, when the wild butterflies are getting scarce. Now and then these pretty butterflies abound on Ivy blooms, from which they may be taken with the fingers, so intent are they upon the honey.

Mr. Inglis in front of his House at Drumlanrig.

Our Kentish Hop grounds have lost the comma butterfly, which used to be rather common locally; but the insect is still to be found in some counties. Its caterpillar feeds upon the Red Currant as well as the Hop, so the butterfly sometimes appears about gardens in spring and autumn. The wings are curiously angled. Stragglers from amongst the meadow species of butterfly wander over flower beds, especially the prettily marked *Pyrarga Megæra*, also called the wall butterfly, from its habit of alighting upon walls or palings during its excursions in the sunshine.

Again, we have sundry small butterflies which give liveliness to our flower domain, varying with the season. Very notable are some of the blues, especially *Lycana Icarus*, common from May to September, the males being pure blue, the females blue mingled with brown or grey. Deeper in colour is the azure blue, *L. Argiolus*, flying in May or September. Its little caterpillar lives upon the flowers of Holly and Ivy. Bright and pugnacious is the small copper butterfly, which likes to drive its companions away from flowers. It is fond of those of the *Verbena*, and is about in early summer, also during autumn.—ENTOMOLOGIST.

## SOIL FOR STRAWBERRIES

The New Jersey State Experiment Station (U.S.A.) has made a fruit survey of that State, and reports that for the northern section of the State 65 growers preferred a sandy soil for Strawberries, 18 a clay loam, and 3 slaty soils. In the central section, 57 growers preferred sandy soil and 23 clay loams. In the southern section of the State, where the great majority of Strawberry growers are located, 625 preferred sandy loam and 349 clay loam soils. From the southern section statistics were also obtained as to the yields on the different soils. In 1893 the average yield secured by 290 growers on clay loam soils was 2,909 quarts per acre; on sandy loam soils the same year 240 growers secured an average of 2,508 quarts per acre—401 quarts per acre in favour of the heavier soils. The following year the differences were still more marked. On a clay loam the average yield of 306 growers was 3,223 quarts, while on sandy soil 387 growers obtained an average of 2,359 quarts per acre—a gain of 864 quarts for clay soils. On the whole it would seem that wherever yield is of special importance, clay loams are likely to make the most satisfactory Strawberry beds. For early crops, however, it is advisable to select a quick, sandy loam, southern exposure, and early varieties; for late crops, a northern exposure, clay soil and late varieties.

## Drumlanrig Castle.

Overlooking the picturesque valley of the River Nith in the neighbourhood of the village of Thornhill, in Dumfriesshire, stands the massive pile known as Drumlanrig Castle, the principal Dumfriesshire seat of the Duke of Buccleuch and Queensberry. A stately building it is, the embodiment of strength and solidity, and quite in keeping with the standing of the noble family to which it belongs. Somewhat grim in some of its aspects, and typical in its appearance, as a writer once said, of the feudal power, its sterner features have of late been softened by the mantling growths of Ivy and of *Ampelopsis Veitchi* (*Vitis inconstans*), which give its sandstone walls a gentler aspect, and seem to typify the beneficent influences which were exerted by recent and present owners in the district around. A noble building it is, and vast in its dimensions does it appear as we stand beneath it and gaze at its many-windowed walls. Its erection dates back to the time of the Douglasses, when William, the third Earl, and first Duke of Queensberry, and Lord High Treasurer of Scotland, erected it on the site of an older castle, whose dungeons are said to have been retained for the wine cellars of the new castle. In the old building James VI. of Scotland paid a visit to the Douglasses of Drumlanrig, and the present castle was visited by our now reigning King in the year 1871, while other Royal and distinguished visitors have from time to time been entertained within its walls, both in the time of the Douglasses and since Drumlanrig came into possession of the Scotts of Buccleuch.

The architecture of Drumlanrig is mixed Grecian and Gothic, and has been attributed to the designs of Inigo Jones, though considerable doubt prevails on the subject. It is quadrangular in form, with an open court in the centre, and a square tower, surmounted by ornamental turrets, is placed at each angle of the building. The principal entrance is at the north front, and is approached by a long avenue of fine trees. Under the clock tower, the arms of the Douglasses appear in bold relief. The castle was begun about 1679, and finished ten years afterwards, though it was almost unoccupied from the accession of "Old Q." in 1771 until improved by the late duke in 1827.

Interesting as are the decorations of the interior, its historic pictures, and its traditional "bloody passage," said to be paced nightly by the spirit of a murdered lady, our concern is more with the horticulture of Drumlanrig, and thus we must turn to the gardens and what they contain. These have for long years been cared for by men of the highest standing in the horticultural world, and one need not do more than remind the younger and rising generation of the name and fame of Mr. David Thomson, who is now enjoying his well earned retirement near Dalkeith. The older men well know the position Drumlanrig gardens occupied in his time. His successor, Mr. David Inglis, had no light rôle to fill, but that he has done it well, all who see Drumlanrig at the present time will be ready to acknowledge.

The principal flower garden is situated to the west of the castle, and at the base of steep grass slopes kept in perfect order by the scythe. It is composed of a number of beds in the grass, and so planted as to be full of flower at the time when the family are in residence, which is only for a short period in autumn. Begonias and Violas are largely grown in these beds, the moisture and cool temperature of the locality making these plants very suitable for the purpose. Among the Violas most valued by Mr. Inglis are Walter Welsh, the best of the yellows there, although Bullion is also a great favourite. Nellie is one of the best of the whites, and Mr. Inglis thinks highly of the newer Sir Robert Pullar, a bright, telling blue, which is likely to be much used in the future. Among the large number of others grown are Blue King, Duchess of Fife, Lady Isabel, Primrose Dame, Skylark, The Mearns, and the much prized William Neil. Violette is always good. The annual Triumph Asters are also valued. In this flower garden there is a bordering of *Cotoneaster* in the form of the design on the shawl worn by the late duchess on her marriage day. This is somewhat elaborate, and is kept carefully clipped, with narrow gravel divisions between the various portions of the design. All these beds are admirably kept by the special staff for the flower gardens at the castle. On the same side is a pretty Rose garden; a favourite among

the Roses at Drumlanrig being Fellenberg, which lasts in bloom until an advanced period of the season. There are also Roses and other climbers on the walls of the terraces.

On the east side, what was formerly an American garden, occupied by the shrubs usually found in such, is now partially planted with beds of autumn flowers, among the most useful of these being late Phloxes, which do admirably here, perennial Asters, Rudbeckias, Violas, and *Pyrethrum uliginosum*, all useful, late in the year. In the vicinity of the castle there are many fine trees, the most noteworthy being some fine Yews, which must be of great antiquity, and whose size and age can only be appreciated when one walks among them. Thus seen, they cannot fail to be admired, with their great boughs and venerable aspect. An interesting thing to the writer, was a fine specimen of *Acer Negundo* fol. var., which some in Scotland think tender. This specimen was planted thirty-two years ago, so that its success in a cold place like this may satisfy some doubters. Near the castle is a commodious Palm house, at one time occupied with Camellias, but which now contains a number of healthy, clean specimens of the most popular species of Palms.

The main gardens are situate a little distance from the castle, and occupy a site which is admittedly one of the worst on the estate for a garden. Lying low down in the valley, it is exposed to early and intense frosts, which, with the humidity of the atmosphere, cause horticulture to be pursued under considerable difficulties, requiring both skill and judgment to overcome. An annual rainfall much in excess of most of the south-western Scottish districts is experienced every year, and one year's record reached no fewer than 75 in.; while that of the frost experienced during the intense weather of the winter of 1894-5, was lower than in almost any other part of Great Britain. Dahlias were much blackened when I saw them on September 13, 1901, and some other things showed alike early, the same effects of the winter's approach.

In this garden there were many more flowers than one had expected to see. There are several very fine herbaceous borders, replanted about four years ago, and filled with a variety of plants which have been selected with much judgment, so as to keep up a continuous display from early spring until late autumn. Phloxes do very well and last long in flower, and novelties among these and other good border plants are added from time to time. Asters are also largely grown, and many clumps of the old yellow *A. Linosyris*, assisted by *Rudbeckia speciosa* and other yellow Composites, helped to make the borders quite gay. Sweet Peas and other annuals are also grown in some quantity for cutting purposes. Outside the walled gardens there are also several beds of herbaceous and other flowers. Near these, too, there is a long stretch of arches, forming a pergola, covered with Clematises, Aristolochias, and other climbers. This seems to be an old feature of the garden. Dahlias are also grown to some extent, but Mr. Inglis purposes using more largely than in the past, the old decorative Glare of the Garden for effect in the borders, the modern Cactus Dahlias giving little show for this purpose. As the requirements of the family throughout the year in the way of vegetables are mainly supplied from Dalkeith, culinary produce of this kind is not much cultivated, except for the brief stay of the household at the castle. The most suitable and best types of vegetables are, however, cultivated with success.

As is well known to readers of the Journal, fruit has always been one of the features for which Drumlanrig has acquired renown. This, however, must be said with some qualification, as neither outdoor Apples nor Pears have given satisfaction, due partly to the soil, but in part the climate. The Pears are not so accommodating as the Apples, and even those on the walls do not satisfy Mr. Inglis. Soon after entering on his duties about eight years ago, he took in hand the planting of young Apple trees with a success which has surprised able gardeners, who did not anticipate good results from the methods adopted. These trees were thus among the things one specially desired to see, and it must be said that they showed surprising results, such as might well be the envy of those in more favoured gardens. All the old and worn-out trees were discarded, and young, healthy trees on the Paradise stock, planted on the surface and mounded up. By liberal feeding, keeping the roots on the surface, and replanting every three years, the trees grow well, bear freely, and colour up splendidly. I noticed, among others, fine crops of such Apples as Queen

Caroline, Warner's King, Gascoigne's Scarlet, Lane's Prince Albert, Bismarck, Graham's Jubilee, the old Galloway Pippin, and especially a tree of Peasgood's Nonesuch, with Apples quite fit to give a good account of themselves on the exhibition table.

The glass department is very extensive, and has all been overhauled, and several capital new houses put up in place of some of the old ones. The Vines have always been well done, and no effort is spared to maintain the reputation of the place for its Grapes. Gros Colman, as grown at Drumlanrig, is the favourite of His Grace the Duke of Buccleuch; but among the other favourites are Black Hamburgh and Muscat of Alexandria. A whole house has been planted with Mrs. Pearson, of which Mr. Inglis has formed a good opinion, and which promises well. Among the others are

under glass, and which showed great promise. Pelargoniums are much grown, and the Zonals, as well as the Show and Fancy varieties, are represented by the latest introductions. Space will not permit of the names of even the best of these. Eucharises attracted my attention from their vigour and absolute health.

This floral department under glass would require an article to itself, as there are so many things to notice, from the collection of cool Orchids being got together again, the deliciously fragrant *Pergularia odoratissima* in the Pine house; *Reidia glaucescens*, *Gloriosa superba*, the lovely old *Callicarpa purpurea*, *Tillandsia zonata*, or such things as *Fuchsia Countess of Aberdeen*, *Heliotropes*, &c. One might have taken notes ad infinitum. All, too, bore the marks of good culture, and the most absolute cleanliness reigned

Drumlanrig from the South.

Duke of Buccleuch, Alicante, Mrs. Pince, and Buckland Sweetwater. Figs are extensively grown. Brown Turkey is the mainstay, and crops abundantly; but others are St. John's or Pingo de Mel, Negro Largo, White Marseilles, and Brunswick.

It was a treat, too, to look through the Pines, and to see such a thriving lot in their various stages. Melons were also good, the favourite being a green fleshed one, raised at Drumlanrig, which is a capital cropper, and of excellent flavour. Among the Tomatoes the most useful is one named Drumlanrig, also raised in the gardens, though Stirling Castle is also found very useful. Other fruit under glass must be passed by, as there are too many things still to remark upon.

The floral department under glass is more extensive and varied than one expected. Chrysanthemums are grown for large blooms to the number of about 1,400, and were ready for housing, all but some of the earlier varieties already

throughout. A good feature was the number of small decorative plants for the table in small pots. Here and there outside, too, in the yards, and on the walls of the bothy, and potting sheds, were interesting shrubs, and it broadened one's estimate of its hardiness to see *Ceanothus azureus* in perfect health and blooming freely there. It may be observed that the smoke from the furnaces and the gas works is carried to a high chimney stack on the hill behind.

One must, however, bring these lengthy, yet for the subject too brief, notes to a close. Yet it cannot be done without a reference to the kindness experienced from Mr. Inglis and the bright family household in his picturesque, flower embowered home, which looks upon the garden over which he presides so well. For this and for the gardening pleasure afforded me I can only express my sincerest thanks, and present this imperfect appreciation of his work.

—S. ARNOTT.

### Apple, Newton Wonder.

In your issue of September 25 you mention that you "believe" Newton Wonder Apple does not do well in Kent, whereas it succeeds well. We have a standard tree, thirteen years planted, that has borne well for some years—8½ bushels on one occasion—and the tree is a magnificent specimen, some 24ft high and 30ft through, the picture of health and vigour. The dwarf trees on the Paradise, commence to bear the second and third years, and they are very happy on this stock. Our original specimen, in basin shape, is full of fine fruit. Our best Kent growers have already found out its value, and we have sold them many thousands. It cannot fail to beat Wellington, as it not only makes a large tree, but is not so subject to damage by severe frosts, mildew, and insects as Wellington is. We have also noted that Bismarck does not do well at Barham Court, Maidstone, although so near us. It grows remarkably well in our nurseries, and is a great success in some orchards near by. It does not possibly like restriction in pruning. The young quarters in our nursery have been so fruitful that they would purchase the ground they stand on. It grows large with us, colours finely, and keeps well into February.—GEO. BUNYARD AND CO.

### Red Spider on Vines.

I should like to state, in answer to Mr. T. Challis' note on page 321, that the atmospheric conditions of the pit were specially attended to, extra air being left on all day. The Crotons were syringed once only, and that in the early morning, and as the day was very fine I need hardly state that there was a very small amount of moisture in the pit. When the lamp was lit, all the crevices were filled with paper, so that none of the fumes should escape. The heat was left on all day to help in drying up the pit. The pipes, which are 3in, and four in number, run through the pit, two of them on the ground level, and 2ft from each other; the other two are at the back and front, and 1ft from the glass. No damping down was done that day, so the experiment was carried out very fairly and honestly. In answer to "C.," page 321, I may say that the XL All was of good quality, as some from the same bottle, and used at the ordinary strength, easily killed green fly. I agree with "C." that we are still waiting expectantly for an article that will kill red spider without damaging fruit, flowers, or foliage. I should not have commented on "H. D.'s" original article, entitled "Seasonable Hints on Vines," which appeared on page 24, but for the fact that I have proved over and over again that this vapouriser does not kill red spider, with me at all events, even when vapourised on two successive nights, at double strength, too; hence my attempt to kill it at twenty-five times the usual strength.—A. JEFFERIES, Moor Hall Gardens, Essex, October 4, 1902.

### Fruit Nomenclature.

The reports on the great fruit show at the Crystal Palace have led me to point out some errors which should not pass without an endeavour to correct them. Apple Potts' Seedling is, in the "Fruit Manual," "Potts's Seedling," and said by Dr. Hogg to have been raised by Mr. Samuel Potts, of Robinson Lane, Ashton-under-Lyne, about the year 1849. In very many catalogues it is entered "Pott's," and in one or two cases "Potts"; the latter would do as well as the entry in the "Fruit Manual," but Pott's is decidedly wrong. Thompson Pear, strange to say, is entered "Thompson's," not only in the "Fruit Manual," but in every other catalogue I have met with (and in the Horticultural Press), except in "Scott's Orchardist," and he entered it "Thompson, Vlesembeek, Van Mons," but as Van Mons was the raiser, it should have been entered "Thompson (Van Mons), Vlesembeek." Dr. Hogg proves this in his notes under "Thompson's," for he states "that it was raised by Van Mons, and being received from him by the Horticultural Society without a name, Mr. Sabine named it in honour of Mr. Robert Thompson."—SENEX, Devon.

[Even the Royal Horticultural Society's schedule of the exhibition of British-grown fruit is not faultless in the matter of nomenclature. Pear, Souvenir du Congrès, is there given as Souvenir de Congrès. A mistake is sometimes made in journals and elsewhere with the name of the Pear Bergamotte Esperen, which is rendered as Bergamotte d'Esperen. Pear Fondante de Thriot may often be noticed as Fondante de Thirriott, which

is wrong; likewise Spencer Nectarine should be Spenser, the name being that of the sixteenth century poet. Peasgood's Nonesuch Apple is frequently written as Peasgood's Nonsuch, and other instances might be given.—ED.]

### Best Quality and Best Forcing Nectarines.

On page 317 I have given Stanwick Elruge as the best quality Nectarine, and Pineapple as the best forcing Nectarine. This is just the reverse of what I intended, as I consider Pineapple the best quality Nectarine, and Stanwick Elruge the best forcing Nectarine. Perhaps some growers may have something to say on the selection of Peaches and Nectarines for the several purposes, and also the best quality and best forcing Peaches and Nectarines.—G. ABBEY.

### Strawberry, Saint Antoine de Padoue.

After three years' culture this excellent autumnal variety has much improved, and we are gathering very fine fruits, some up to 1½in across (cock's combed), of excellent flavour, and they promise a season of some four weeks' supply, which makes a novelty at this season. The older kinds must give way to it, as the "Saint" is a much better bearer, and the fruit larger and of finer flavour. "Just like the first June Strawberries," as a lady said.—GEO. BUNYARD, Maidstone, October 3.

### Carrots on Ridges.

It may not be generally known that Carrots of magnificent form and quality can be produced upon ridges. A trouble hitherto, with me, has been their splitting, but since adopting this system it has been practically eliminated; the Carrot-fly also being less noticeable. After deeply digging, the ridges are made up about 10in in height, and a slight depression made along the top, in which seed is sown. I have already drawn some wonderfully lengthy specimens, and perfectly free from blemish.—S.

### Late Strawberries.

The advantage of cultivating the perpetual bearing Strawberries is now being appreciated, despite the unpropitious weather. I have not yet tried the latest varieties, but St. Joseph and Louis Gauthier are now (October 6) fruiting splendidly. Regarding the latter, these white varieties do not appear to be popular, and never will be, for market work; but for the home garden they should not be omitted. Louis Gauthier this season produced a far heavier crop than any of my forty varieties, the flavour being excellent and the size immense, considering the smallness of other sorts.—SQUIB.

### The Lady Gardener.

The prospects of the citadel of horticulture being razed to the ground by the lady gardener, however humiliating the idea may be, is eminently pleasing. There are many thoughts embodied in such a prospect that certainly claim the attention of everyone who is able to rise above ordinary prosaic sentiment. We leave it to the imagination to depict the pleasing picture one shall find in the rosy future on entering one of our larger gardens, and compare that with things as now existing. This is the lady's realm. The Roman wives are said to have been the keepers of the garden, but the regulation of the Viridarium in some mysterious manner, and at some time unknown to history, passed out of the hands of the lady to the custody of man; and, like tailoring, it got eventually quite beyond the prescribed domains of woman's sphere, till it reached the critical stage it at present is about to experience. Gardeners and tailors (I mean men) were wont to consider this translation of their respective arts, the renaissance. Perhaps they were right, but tailoring and gardening, notwithstanding, are essentially women's arts. And we must admit the facts, sooner or later, and look with complacency at the inevitable—usurping if you like—invasion of women craft into the arena of practical horticulture. And yet it may admit of very much doubt if, after all, the claims of use and wont are capable of adding more superlative honours to the art, for why should women not be as capable to promote and advance the work as men?

Men, we have ample justification in testifying, are not likely to improve matters very much beyond the present state of things, for if we but look about us, the external, as well as the internal, evidences stare us in the face. The spade, the scythe, and the barrow are surveyed by the modern young gardener with something approaching contempt, while the sponge, the scrubber, and washing cloth elicit the fondest smile. After all, there does not seem to be such an alarming difference between the two opposing powers in whose hands hang the destinies of the future of the art of gardening.—C. H. S.

### Wanted—Inventors.

It may be of interest to your correspondents and others to know that "the instrument of torture" of which complaint is made, viz., the ordinary garden barrow, is being abolished in some places, and superseded by an instrument, if not of pleasure, at least one of ease. It is a pleasure to see with what small effort a boy can ply to and fro with heavy loads of plants by the use of the Improved Plant Barrow (particulars of which I enclose on a printed slip), whereas with "the instrument of torture" complained of, two men would have to work hard with less results.—R. E. SANDERS.

Exactly so! More power to you, Mr. H. Muncey, for your sort of a set-on-a-thinking article with which you led off our weekly feed of good things on September 11 (page 235). It was a palate tickler. We gardeners do want a lot, no doubt. "Man never is, but always to be blest." No man knows what a gardener wants so well as the gardener himself. He is, too, as "chokeful of science as old Sol Gills." Does any critic doubt it? Know, then, oh ye of little faith, that it is so, and that it only wants the Muncey method to set it leaking for the benefit of gardeners now and generations yet unborn. Still doubting? Then I'd have you to know that the article swallowed last night is so sudorific in its action that, this morning, it's oozing out of me at every pore; 6 a.m., waiting for the laggards; why tarries the crinch-crunch of their big brogues? Ah! The back tyre—my beloved free wheel—no sooner catches the eye than my hand catches the pump (inflator), one of those celluloid affairs. Wish-shoot, wish-shoot, wish-shoot, just three strokes; grand. A cyclist's blessing on thee, O celluloid man, whoever thou art; but, and to the point, thrice blessed be he by all gardeners who will give us a celluloid syringe. Oh! do, somebody who knows somebody else—some benevolent body in the celluloid trade—do tell him and let us have one, and if it is the success I guess it would be, then call it the Muncey.—Q.

I read with much interest Mr. Muncey's article, and, like him, I think it is high time we had some improvement in our everyday tools. Take, for instance, the lawn mowers; what a drag even the best of them are! Now, this does not come from the mere cutting of the grass, for with well ground knives and a keen sole plate, little weight is required for that. The dead drag comes from the sole bar trailing on the thick turf. To prove this, one has only to turn up a machine and see it polished like the fire-irons. If makers of mowers would keep their sole bar farther back, and higher up in the heel, so as to entirely clear the turf, they would save gallons (!) of sweat, both to man and beast. Only the edge of the sole plate, or bedknife should come in contact with the turf.—J. LORNE, South Park, Rothesay.

### Where is the Todea?

Not so many years ago the Todea formed an important addition to the fernery of almost every well constituted garden. To-day scarce any of the varieties then in repute are to be met with in gardens. Assuming that every effect has a cause, it would be interesting to discover the reason for this falling off in repute of such a graceful and unquestionable requisition in the complete decoration of the fernery. Its culture is by no means difficult—that is, unless it is cultured too much, and that may be possible in some cases, and ought not to be a cause for the complained non-representation in ordinary collections. There may be a more palpable cause in the vagaries of fashion, and perhaps it is to her door the reason must be traced. Fashion truly is a capricious dame, responsible for perhaps more evil than good to gardening.

Raw and loose jointed, a few years ago it was our destiny, like most gardeners, to find our way to the Scottish metropolis, and we lost little time in wending our way to the then celebrated Lawson nurseries. While most of all we saw was new and full of interest to a country boy, nothing took us with such force as the long span-roofed Todea pit. The sight was truly magnificent to us then, still is, and possibly ever shall be, for we do not think it easily could be rivalled. The plants were ranged along either side of the footpath which went up the middle of the house. The long graceful pendant fronds fell down the walled sides of the path, almost touching the ground. Not the less beautiful were those former denizens of the Antipodes, when often in winter their delicate fronds could be seen encased in ice, and hanging therefrom countless icicles. Todea superba comprised the greater number, and perhaps the most imposing, though there were one or two other varieties represented. The Todea being a Filmy Fern, it requires perfect shade and ample overhead moisture. This necessitates a small corner specially for itself in the fernery, hence probably another serious obstacle to its general distribution in gardens. Still, this latter reason is not sufficient, for in most places such a trivial obstacle could easily be removed. It is to be hoped that the Todea will yet return and become a universal favourite among the beautiful though flowerless class of which it is a subject.—D. C.

### The Fern Mite.

In reply to "Trem," page 307, I can truly sympathise with him in having charge of thousands of Ferns infested with the mite, more particularly as he is growing them for the market. It is quite bad enough to have a few solitary plants so infested, but when it amounts to thousands, and relying on them for a living, it becomes a most serious matter, and from what I saw of Mr. Nash's Ferns already referred to, I felt certain that what his were troubled with was not a solitary case, as what had affected him would make its appearance elsewhere, and that is why I sent my paper for publication in these columns. At the present time I cannot say if the mite that "Trem" has been fighting is the same variety as the one that Mr. Nash has been troubled with, and I would be glad if "Trem" will oblige by sending me a plant or two in pots, as grown—the worst infested plants he has got—carefully packed, to 21, Church Road, Wimbledon, so that I may ascertain if it is the same insect. The plants should have some young fronds just bursting up from the crowns, as it is on these that the insects are found, and to which the mischief is done, as immediately the fronds get slightly hardened the insects return to the crown of the plants to infest the next fronds that appear. These, in turn, are crippled before being developed.

As I have already stated, these insect pests are new to me. Mr. Nash is a nurseryman, and the loss of a quantity of Ferns just at a time he expected to turn them into money was a serious matter, and in looking through his houses I noticed a batch of them looking very stubby, the upper portions of the fronds having been cut off and the lower ends left. In the majority of them more than half the fronds were gone, and what remained had just the appearance as described by "Trem" on page 307. I at once inquired what was the cause of it, to which Mr. Nash replied, "We are puzzled to know. We believe it is an insect. We have fumigated and used all kinds of liquid insecticides, but nothing seems to stop them, and now we are applying a liberal use of the syringe to see what effect that will have," &c.

I brought away a plant, and after examining the soil and roots I found the insects seated in the crown of the plant and on the tenderest fronds, and under an objective of high power could fully define the insects, also their eggs in various stages, and by referring to my books I was able to identify them as the *Macrobiotus Hufelandi*. Having found out what it was, the next thing was to know its natural habitat, i.e., under what conditions it lived and thrived. It is figured in the *Micrographic Dictionary*, and described "as being found upon mosses growing on walls, stones, at the foot of trees, &c." It is also described in the "Manual of Zoology," by Nicholson; but more fully so in volume 6 of Messrs. Cassell's "Natural History," where it is described in the order of Tardigrada commonly known as bear or sloth animalcules, found in moss and in wet places.

The mouth is suctorial, and they are distinguished from all other Arachnidae by being absolutely hermaphrodite. The single ovary containing its eggs is always visible in the hinder part of the body, and at the posterior end of it are placed the male organs, both sets opening into a dilatation of the intestinal canal, &c. They live sometimes in water, but more frequently in moss, in damp places, and some of them are found especially in a rather curious locality, viz., in the gutters of the roofs of houses, and have the power of resisting desiccation. They may be found apparently quite dry among the sandy dust of a gutter, and will revive at once on being duly moistened.

Having found out the natural habitat of the insects, the next question is, What will destroy them? and, seeing that they thrive in moist places, points at once that insecticides in a fluid state are practically useless. Also, as they infest the crowns of the plants and the tenderest growth of the fronds, fumigation is hopeless. I therefore advised giving the plants a thorough good watering and then dust the crowns completely with tobacco powder, or any other strong insecticide in a powdered state, and repeat the dusting after the next waterings.

The plants began to thrive, and were soon in saleable condition. I will here say the insect, being hermaphrodite, i.e., the male and female organs existing in the same individual insect, it therefore has the power of reproducing itself as long as it lives or one is left; and although the cultivator may burn all his plants, a legion of the vermin may be left lodged under the wall plates, in the walls, under the stages, or in the gutters of his houses, to sally forth and infest batch after batch of his plants; hence the necessity of not only cleaning the plants, but every particle of the house in which the infested plants are grown in.

The eggs of the insects are situated in them as described, and are discharged three at a time in a very thin coating or sack. They are of a beautiful pale green colour, and it is most interesting to watch the young insects relieve themselves from the egg itself, after which the coating, or sack, that contained

the eggs has the appearance of a tiny bit of scarlet thread. After reading "Trem's" letter I paid Mr. Nash a visit to see if he was quite free from the vermin, but there were several plants that are infested now, and I am quite convinced that it is no easy matter to stamp it out after it has got a firm footing; no half measures will do it.

As regards the *Oribata demersa*, it is a totally different insect, although it exists under similar circumstances, and from the effect they had on the *Aspleniums* they appear to be as bad an enemy; but after a free use of the tobacco powder on the crowns the plants began to grow, and were soon sold out. The *Oribata* are described in the last edition of "The Microscope," by Carpenter, as "vegetable feeders, living in moss, lichen, fungus, dead wood, under the bark of trees, &c., and some few species on aquatic plants. They are widely distributed, from the Arctic regions to the equatorial."

I hope "Trem" will send me a plant, and after finding out under what circumstances his enemy thrives he will have a better idea as to what remedy to apply, and if I can be of any service to him by way of advice I shall only be too pleased to give it.—J. OLLERHEAD.

## Book Notices.

### The Natural History of Plants.\*

The "Natural History of Plants," by Professors Kerner and Oliver, is so well known that one hardly requires to describe its extent and treatment. As a popularly and lucidly written work on the nature, work, functions, and relationship of plants, it is almost indispensable in the gardener's library. It is a scientific work, yet one whose style is attractive, and which unfolds the history of vegetable life in a way as interesting as any story of human achievement. Four parts, each of about 110 pages (10in by 7in) have been issued in this reprint, and there are twelve more monthly parts. It is a useful book, too, for reference, and heartily we commend it to the notice of gardeners, the young men especially. The printing, paper, and illustrations are alike excellent.

### Vegetables and Flowers from Seeds.†

The cultural directions furnished for the different vegetables and flowers treated in this book are sufficient for all who have a fair practical acquaintance with flower and kitchen garden crops. After presenting the necessary advice on matters of practice, the following in reference to Carrots is how their wants in other climates are summarily recorded:—"For Egypt and other countries immediately south of the Mediterranean, October is the sowing season for main crops of Carrot, but the time can be greatly extended under irrigation. In Australia this is one of the most popular roots grown. Seed can be sown successively from February until September, and it is desirable to mix with the Carrot seed a few seeds of Turnip or Radish, which come quickly and mark the rows. To ensure the retention of moisture the soil must be made firm. Where the land is cold, three weeks elapse before germination.

"In South Africa, garden sowings of Carrot seed are made from August until October, and on a large scale from January to March. For the Argentine Republic, winter and spring are suitable for sowing seed, but there is no difficulty in maintaining a succession by a series of sowings extending through the entire year."

In regard to Leeks, there is the following paragraph:—"In the Himalayas, Kashmir, China, Japan, and Canada, seed should be sown immediately frost has gone, or perhaps a little earlier, on a hotbed, under protection at night. May, June, and July are the months for South Australia. In South Africa, temperate South America, India, Burma, and Ceylon sowings may be made at an altitude of 2,000 feet in August, and at the sea level in November. During October, the interval of calm between the south-west monsoon and the north-east current is the trying period for young plants of all kinds."

Little is said of the culture and behaviour of the Brassica and Turnip tribes in tropical or even semi-tropical countries; fuller information in this respect would have added to the value of the book. Perhaps, too, a summary statement of the climate and physiography of the main divisional features of the globe would also have added character to the book. It will prove a useful book for colonists without doubt, and we commend it to the notice of those who are in foreign parts, or who are about to go. It is brightly illustrated to the highest quality paper, the typography being excellent, and a good index is included. The price is not stated, but may be 5s. net. (pp. 331, 8½in by 5½in.)

\* "The Natural History of Plants," Kerner and Oliver. Blackie & Son, Ltd., London, Glasgow, Dublin. Price per part, 1s. 6d. net.

† "Vegetables and Flowers from Seeds in Tropical, Semi-Tropical and Temperate Climates," by Sutton and Sons. Published by Sutton and Sons, Reading, England.

## PERENNIAL ASTERS.

The season of Michaelmas Daisies is now reaching its zenith, and but for them the garden would be much less bright than it is. During hard weather, when sharp frosts and early snowfalls have checked or killed nearly every other herbaceous plant, one can still rely on the continued flowering of the perennial Asters until the middle of November. Their culture requires but little note; they enjoy good treatment, and fair attention in such matters as thinning and tying the shoots, mulching during the summer if the soil is light and poor, and for such care the plants will return a bright display of beautiful flowers and dark, healthy leafage. The illustration of a posy of perennial Asters on page 341 exhibits forms of species of the genus, including *A. ericoides*, at the top, with small flowers; *A. acris*, the starry bunch beneath it; *A. Amellus* var., the largest flowers in the figure; *A. cordifolius* var., at the top right-hand corner; and *A. Novæ-Angliæ* var., the bottom right-hand blooms. *A. Novi-Belgi* is another well marked species, whose many varieties, with itself, form "a section" in the horticultural classification. The following are good varieties worthy of cultivation in gardens:—*CORDIFOLIUS*: Photograph, Diana, elegans, major, albus, and magnificus. *AMELLUS*: cassubicus, latifolius, amelloides, Onward, bessarabicus, Framfieldi, and Riverslea. *NOVI-BELGI*: T. S. Ware, Arcturus, Calliope, Harpur Crewe, Madonna, Candida, formosissimus, William Marshall, and Robert Parker. *NOVÆ-ANGLIÆ*: Diadem, Mrs. J. F. Raynor, præcox, Pæcicité, roseus, William Bowman, and ruber. Other good sorts are *Coombe-fishacre*, *Tradescanti*, *vimineus*, *ericoides densus*, *grandis*, *levigatus*, *ptarmicoides*, and Councillor W. Waters.

## Societies.

### Royal Horticultural—Drill Hall, Oct. 7th.

The meeting of Tuesday last was typical of the autumn season, there being quite an abundance of hardy flowers, Dahlias, and fruit and vegetables. Messrs. J. Hill and Son had a group of the Bird's-nest and other handsome Ferns, while Mr. John Russell, of Richmond, filled the centre of the hall with a varied collection of Ivies, all in pots, and trained as standards, bushes, and columnar specimens. From Dobbie and Co., Rothesay, came fifty basket-lots of Potatoes, in as many distinct sorts. These we refer to under Fruit and Vegetable Committee. Two collections of fruit were presented, one from Mr. J. H. Goodacre, gardener to Earl of Harrington, at Elvaston Castle Gardens, Derby, and another from Mr. W. Fyfe, gardener to Lady Wantage, Lockinge Gardens, Wantage, who also staged a collection of vegetables as a section of the same exhibit. Chrysanthemums from Mr. J. Surman, of Beckenham, and Messrs. Wells and Co., of Redhill, Earlswood; while Messrs. F. Cant and Co., and B. R. Cant and Sons, furnished each a magnificent collection of cut Rose blooms. Mr. R. W. Green, seed grower, Wisbech, who grows specially for the trade, staged a collection of newer varieties on this occasion, each being meritorious, and which we may again refer to. Messrs. E. A. White, Limited, Beltring, Paddock Wood, Kent, sent a collection of Apples on branches, the fruits and foliage all very clean and bright. The "Spimo" improved fruit tree wash had been used on the trees.

### Floral Committee.

Present: W. Marshall, Esq. (in the chair); with Messrs. H. B. May, Chas. T. Drury, J. Hudson, J. H. Nix, Chas. Dixon, J. Jennings, Geo. Gordon, Chas. Jefferies, H. J. Cutbush, C. J. Salter, Chas. E. Pearson, R. C. Notcutt, W. P. Thomson, Wm. Cuthbertsen, J. H. Fitt, C. R. Fielder, E. T. Cook, R. M. Wallace, and Ed. Mawley.

Messrs. Ware, Limited, contributed, amongst their varied collection of Asters, the pretty white multiflorus, and the lavender-purple *A. N-B.* T. S. Ware. Aster Wm. Bowman was also showy, and so too, Mrs. Raynor. Among Cant's Roses were bunches of Killarney, Mme. Pierre Cochet (a deep W. A. Richardson), Billiard et Barre, golden orange; Safrano, tea-coloured; and the charming Rosette de Legion d'Honneur.

Messrs. Cheal and Sons (Crawley) group showed how much better it is to stage only a few bunches of Asters, and stage them well, than to fill a whole table with small bouquets closely packed. Their selection included *A. multiflorus albus*, *A. Amellus bessarabicus*, *A. Harpur Crewe*, *A. N.-A. rosea*, and the handsome *Helonium autumnale striatum*. They had a very fine collection of Dahlia blooms, Pompon, single, and Cactus.

F. A. Bevan, Esq. (gardener, Mr. H. Parr), Trent Park, New Barnet, brought up a collection of Michaelmas Daisies, and from Messrs. J. Peed and Sons, of Norwood Road, London, S.E., also came these Asters, with Dahlias and hardy flowers in general.

CHOICE PERENNIAL ASTERS.

Mr. John Forbes, Hawick, Scotland, was south with some of his specialities, as Pentstemons, Phloxes, Carnations, and Begonia Caledonia in pans. His strain of Pentstemons proved to be an advanced and good type. We may name the following as good varieties: James Farquhar, J. Ramsey, Dragoon, Mrs. Oliver, Pres. Carnot, Mrs. Dawson, Edward Tyndale, J. N. Troup, Mrs. Roberts, and Royal Standard. Among Phloxes were Sylphide, Sheriff Ivory, John Forbes, and Wm. Ramsey. One of the best Carnations was the dark red Royal Standard.

The Shirley Nurseries, Southampton, sent their quota of hardy flowers, and Messrs. Barr and Sons, of King Street, Covent Garden, massed perennial Asters, Gladioli, Kniphofias, Acers, and Geraniums. A bright and varied group. Mr. Amos Perry had also a choice group in this line.

In Messrs. Wells' group, we noted the following as being especially noteworthy: Goacher's Crimson, Orange Masee, Chas. Jolly, Mme. Liger Ligneau (golden), Mytchett Beauty, Roi des Précocés, Alf. Fleuret, and other decorative varieties. Twelve specimen blooms were staged in front, including Mrs. T. W. Pockett, Miss A. Byron, W. R. Church, Rayonnante, Mme. Von Andre, Mrs. W. Popham, Miss E. Fulton, and Mutual Friend.

A splendid exhibit of freely flowered Begonia Gloire de Lorraine, came from Ronald Keep, Esq. (gardener, Mr. S. Pym), Woollet Hall, North Cray, Kent, whilst Messrs. Cutbush had Carnations, and Mr. Prince Roses.

#### Orchid Committee.

Present: Harry J. Veitch, Esq. (in the chair); with Messrs. J. O'Brien, de B. Crawshay, H. Ballantine, F. A. Rehder, E. Hill, H. T. Pitt, G. F. Moore, T. W. Bond, F. W. Ashtott, W. Boxall, W. H. Young, H. A. Tracy, H. Little, Wilson-Potter, and N. A. Bilney.

Orchids were fairly well to the fore. Messrs. Veitch and Sons, Limited, Chelsea, staged hybrid Lælias and Cattleyas, including *L. splendens*, bearing three large flowers on one sheaf; *L. pacuvia*, *L.-c. Bryan*, with four beautiful flowers; *L.-c. Ophir*, a bright cinnamon-yellow bigener, with purplish throat; *L.-o. Hermione*, very large and well coloured; and *L.-c. Aphrodite*, with a grand velvety-purple lip.

H. T. Pitt, Esq. (gardener, Mr. Thurgood), exhibited a group of strongly flowered Odontoglossums, these exhibiting great variety of colour, and were highly interesting. The rare *Dendrobium Victoria Regina* in flower was shown, and also a certificated *L.-c.*, viz., *Iris*, Rosslyn var.

W. C. Walker, Esq. (gardener, Mr. G. Gragg), Bercy Lodge, Winchmore Hill, N., deserved a full measure of praise for the magnificently flowered and healthy Odontoglossum crispum contributed by him. One plant had two racemes, each bearing a dozen massive flowers, and others had single racemes with fourteen flowers.

Messrs. Charlesworth and Co., Heaton, Bradford, sent a few choice Orchids. They had *Sophro-Lælia Heatonensis*, *S.-c. Eximia*, and the hybrid *Cattleya Iris*, amongst other things.

Mr. Hudson, of Gunnersbury, received a Cultural Commendation for a handsomely flowered *Dendrobium formosissimum gigantea*. Messrs. Hugh Low and Co., Bush Hill Park, Enfield, with *Cattleya intermedia flava*, *Oncidium incurvum*, *Cattleya x Firefly*, and *Lælia Harrisoni*, furnished a good show. Other exhibitors staged separate small exhibits.

#### Fruit and Vegetable Committee.

Present: George Bunyard, Esq. (in the chair); with Messrs. H. Balderson, Jos. Cheal, Geo. Woodward, J. W. Bates, S. Mortimer, Alex. Dean, Edwin Beckett, Horace J. Wright, H. Markham, H. Esling, G. Reynolds, F. Q. Lane, J. Smith, C. G. A. Nix, H. Somers Rivers, A. H. Pearson, and O. Thomas.

The Grapes, Melons, Apples, Pears, and Gages from Elvaston were samples of high culture and great attention in treatment.

Messrs. Dobbie and Co.'s Potatoes, which we have already noted, included the following typically good varieties, amongst others:—The Factor, very clean and beautiful; Harbinger, British Queen, Dobbie's Favourite, The Crofter, Pride of the Ochils, Sharpe's Victor, The Sirdar, Sir J. Llewellyn, Maincrop, Duke of York, Snowdrop, Ideal, Dobbie's Improved Kidney, Myatt's Ashleaf, and Duke of Rothesay among the white-skinned, kidney-shaped varieties; and among the coloured Potatoes were Herd Laddie, Eightyfold, Purple Perfection, Edgemoor Purple, Reading Ruby, and The Dean amongst purples; Waverley, Mr. Bresee, Lord Rosebery, and Reading Russet, among pinks. The general verdict of experts was that no finer collection had ever been seen in the Drill Hall, and, indeed, it would be hard to stage or see a finer collection at any time.

Lady Wantage's fruit collection included well coloured and finely shaped white and black Grapes, with Melons, Apples, Peaches, Plums, Pears, Figs, Nectarines, a cone of *Monstera deliciosa*, and a dish of Morello Cherries. Red Ampelopsis foliage was strewn over the white table covering, and the long shoots wound round the various fruit stands. The collection was very creditable, and admirable in every way. The vegetables, too, were clean, crisp, and fresh.

#### Medals.

FLORAL COMMITTEE.—Gold Medal for group of garden Roses to Messrs. F. Cant and Co., Colchester. Silver-gilt Flora for group of Tree Ivies to Mr. J. Russell, Richmond. Silver-gilt Banksian for Asplenium, &c., to Messrs. Hill and Son, Lower Edmonton; for hardy flowers to Mr. Amos Perry, Winchmore Hill. Silver Flora for early flowering Chrysanthemums to Messrs. W. Wells and Co., Earlswood; for Carnations, Phloxes, &c., to Mr. John Forbes, Hawick, N.B.; for hardy flowers to Messrs. B. Ladhams, Southampton; for autumn Roses to Messrs. B. R. Cant and Sons, Colchester. Silver Banksian for Dahlias to Messrs. J. Cheal and Son, Crawley; for Roses to Mr. G. Prince, Kingston Bagpuze. Bronze Flora for Begonia Gloire de Lorraine to Ronald Keep, Esq., N. Cray, Kent. Bronze Banksian for Michaelmas Daisies to F. A. Bevan, Esq., New Barnet. Silver Banksian for perennial Asters to Messrs. Barr and Sons, Covent Garden, and Messrs. Ware, Limited, Feltham.

FRUIT COMMITTEE.—Gold Medal to Messrs. Dobbie and Co., Rothesay, for fifty baskets of Potatoes; to Lady Wantage, Lockinge Gardens, Wantage, for collection of fruit and vegetables. Hogg Medal to Lord Harrington, Elvaston Castle Gardens, Derby, for collection of fruit. Silver Knightian Medal to Mr. R. W. Green, Wisbech, for sixty varieties of Potatoes.

ORCHID COMMITTEE.—Silver-gilt Flora to H. T. Pitt, Rosslyn Gardens, Stamford Hill, for group of Orchids. Silver Flora to Walter C. Walker, Winchmore Hill, for group of Orchids. Silver Flora and C.C. to James Veitch and Sons, Limited, Chelsea, for group of hybrid Orchids. Silver Banksian to Charlesworth and Co., Heaton, Bradford, for group of Orchids.

#### Certificates and Awards of Merit.

*Cattleya x Firefly* (Hugh Low and Co.).—Flowers of moderate size, but of great elegance; pale mauve colour. Award of Merit.

*Chrysanthemum*, *Joseph Lowe* (Mr. G. Shawyer).—A bright and deep yellow Japanese variety. Flowers medium, compact, and rounded in form. Award of Merit. From Cranford, Hounslow.

*Lælio-Cattleya x Iris*, Rosslyn var. (H. T. Pitt, Esq.).—Quite distinct, with petals very broad in the centre and rounded, the velvety purple lip is frilled and silvery-edged, and is broad in front. A close-built flower. Award of Merit.

*Lælio-Cattleya x Madame Chas. Maron* (Baron Schröder).—The parentage is *C. Warszewiczii* x *L. Digbyana*. An immense flower, measuring 7 or 8 in across from tip to tip of the sepals. The colour is very light and bright lavender mauve with a suspicion of pink. The lip is fringed, bold and handsome, with a yellow throat. First-Class Certificate.

*Melon*, *The Peer* (Mr. J. H. Goodacre).—A white, deep-fleshed, juicy fruit. The skin is yellow, and finely netted. It is a cross between Countess and Beechwood. The seed cavity is very small. It is heavy, and one of the finest flavoured varieties we have tasted. Award of Merit.

*Pear*, *Michaelmas Nelis* (Geo. Bunyard and Co.).—The raiser's description is as follows:—"Small, first-class quality; a deliciously sweet melting Pear—free grower and bearer—sent out last year for the first time; there is no other so good in its season. Quince. Season, September-October." Award of Merit.

*Sopro-Lælia x Heatonensis* (Charlesworth and Co.).—An interesting and decidedly attractive bigener, of sharply defined form. The sepals are very pointed, 2½ in long, and tapering. The petals are oval acuminate, slightly sinuous at the apex, and, like the sepals, are rich dark crimson. The lip is long, narrow, and protrudes forward. Colour purple. First-Class Certificate. From Heaton, Bradford.

#### National Chrysanthemum, Oct. 7th, 8th, and 9th.

The early autumn exhibition of the National Chrysanthemum Society, held on Tuesday, Wednesday, and Thursday of this week, in the Royal Aquarium, Westminster, was in every way successful. The whole available space on the ground floor was occupied with groups and boxes of cut flowers, also collections of fruit and vegetables, all of which added to the interest of the show. Mr. Deverill's vegetable classes were well filled, and nice samples were displayed. The decorations were very good this year, though some of the classes were not supported, so far as we could discover. These were few, however, and keen competition was the rule. Amongst the specimen blooms on view there were fine samples of Mrs. T. W. Pockett, H. A. Barratt, Lily Mountford, Alice Byron, Rayonnante, Mrs. R. Darby, Mrs. G. Mileham, Godfrey's Triumph, King Edward VII., Sir W. Acland, and Charles Longley. The well-known supporters of the society were forward in strength. To Mr. R. Dean, in particular, a word of acknowledgment is due.

For a group of Chrysanthemums and foliage plants there were two entries. Mr. W. Howe, gardener to Lady Tate, Park Hill, Streatham, was easily first with well-coloured flowers and a beautiful variety of foliage, which included some well-coloured Crotons and Ferns. Mr. R. C. Pulling, Monkham's Nurseries, Woodford, was second with larger flowers, which exhibited signs of bad damping, while the coloured blooms were poor in colour. The

front was composed of *Pteris tremula* and *Isolepis gracilis*, the back being composed of Bamboos.

For twenty-four blooms Japanese, in not less than eighteen varieties, there were four competitors, the average of the blooms being above the usual standard seen at this particular show. Mr. J. Brooks, gardener to J. W. Newman, Esq., Totteridge Park, Totteridge, Herts, securing the first prize with plenty in hand. His varieties were Mrs. T. W. Pockett (a fine specimen), Miss Alice Byron, Soleil d'Octobre, Florence Molyneux, Mr. H. A. Barratt, Madame Gustav Henry, Mrs. R. Darby, Chas. Longley, Lady H. Clark, Lily Mountford, Madame Alice Capitant, Mr. L. Remy, Mrs. G. W. Palmer, Rayonnante, Mrs. G. Mileham (good), Mrs. Greenfield, M. V. Venosta, and Lady Crawshaw. Mr. G. Impey, gardener to H. Mansfield, Esq., The Lodge, Abbots Road, New Barnet, was second with good flowers of Millicent Richardson, Mrs. R. Darby, Lady Audrey Buller, Edith Pilkington, Mrs. J. J. Thorneycroft, and Madame Gustav Henry, while Mr. N. Davis brought up the rear, staging good flowers of J. R. Upton, Charles Penford, Mrs. Harry Emmerton, Kimberley, and Baden Powell.

The class for twelve blooms, Japanese, distinct, there were no less than six entries, the first prize being awarded to Mr. H. Perkins, gardener to the Hon. W. F. D. Smith, Greenlands, Henley-on-Thames, for a level board, decidedly above the average for an October show. His varieties were Sir W. Acland (a grand flower), Jane Molyneux, Mrs. J. Bryant, George Lawrence, Mrs. W. Popham, Seedling, Lady Acland (a good yellow), Madame A. Capitant, Seedling, Graphic, Seedling, and Mary Perkins. Mr. James Brooks was second with a weaker display, his best varieties being Madame Gustav Henry, Rayonnante, Mr. L. Remy, and Lily Mountford; and Mr. M. Rayment, gardener to W. Beech, Esq., North Ockenden, Romford, third.

Class 4, for six blooms, distinct, only produced four exhibitors, the first position being taken by Mr. R. C. Pulling, Monkham's Nurseries, Woodford, who staged moderate blooms of Lily Mountford, Madame Von Andre, Evelyn Douglas, Madame G. Henry, May Vallis (good colour), and Mrs. Greenfield. Mr. J. Childs, gardener to Mrs. Foss, The Priory, Totteridge, Herts, who had good blooms of Rayonnante, Soleil d'Octobre, and Lady Crawshaw, was second, Mr. S. Foster, gardener to R. Nivison, Esq., Tenterden Hall, Hendon, being third.

For six blooms, incurved, not less than three varieties, there was only one entry, from Mr. Jas. Agate, Brockhampton Nurseries, Havant, who was awarded the first prize for a good board at this season, his varieties being Mons. R. Baluant, Lord Coleridge, and Matthew Russell.

In the class for twelve bunches of early flowering pompons, not less than eight varieties, there were three competitors, the first prize falling to Mr. Eric F. Such, nurseryman, Maidenhead, who staged a good lot of disbudded flowers, the varieties being Pink Martinmas, Bronze Martinmas, Peach Martinmas, Blushing Bride, Madame E. Lefort, Mrs. Cullingford, Strathmeath, Longfellow, and La Vierge, a splendid exhibit but very misleading as to the decorative value of the varieties for garden decoration. Mr. T. L. Turk, gardener to T. Boney, Esq., Southwood House, Highgate, was second with good bunches of Mrs. Cullingford, Miss Davis, and Alice Butcher; Mr. Charles Brown, gardener to R. Henty, Esq., Langley House, Abbots Langley, third.

In the class for six bunches of early flowering pompons distinct, not disbudded, there certainly was a much better display than the previous class. Here Mr. D. B. Crane, Archway Road, Highgate, scored with splendid bunches of Anastasia, Alice Butcher, Flora, Mrs. Cullingford, and Fiberta; Mr. E. Such following with nice fresh bunches of Martinmas, Madame E. Lefort, and Peach Martinmas; Mr. Charles Brown being third.

The class for a pair of vases to contain twelve blooms, large flowering varieties, brought four entries, which formed a capital display, the premier award going to Mr. James Brooks, who staged two splendid vases of specimen blooms. Mr. J. Kirkwood, gardener to E. Wormald, Esq., Grass Park House, Finchley, was second with rather weaker flowers, though well arranged, and Mr. N. Davis third.

For one vase of six blooms, one variety, yellow, there were no less than six competitors, Mr. R. C. Pulling leading with superb blooms of Mrs. T. W. Pockett. Mr. H. Perkins followed with Mary Perkins, a Japanese of the incurved type, while Mr. F. Bush, gardener to W. F. Lister, Esq., Rose Hill, Totteridge, was third.

There were seven contestants in the class for six blooms, white, one variety, and the premier prize was allotted to Mr. G. Impey, gardener to H. Mansfield, Esq., The Lodge, Abbots Road, New Barnet, who staged a fine vase of Madame Gustav Henry, Mr. R. C. Pulling following with the same variety, while Mr. Jas. Brooks brought up the rear with another honour for Madame Gustav Henry.

In the class for any other variety, one variety only, there were five entries, Mr. R. C. Pulling securing leading honours with a good vase of Lily Mountford. Mr. Jas. Brooks was second with paler blooms of the same variety, while the third place was secured by Mr. H. Parr with moderate blooms of Mrs. A. H. Hall.

The entries for class 12, which read as one vase of early flowering Pompons with suitable foliage, brought out five entries, the first being awarded to Mr. D. B. Crane, Mr. T. L. Turk being second, and Mr. S. Foster third.

For twelve bunches, distinct varieties, from plants grown in the open and not disbudded, there were four entries, the first prize going to Mr. D. B. Crane for a splendid exhibit of naturally grown bunches. The varieties were Horace Martin, Madame Marie Masse, Ivy Stark, Mrs. Cullingford, Henri Yvon, François Vuillermet, Harvest Home, Ralph Curtis, Lemon Queen, Crimson Marie Masse, and Bronze Prince. Mr. Eric Such was a good second with nice bunches of Bronze Masse, Lemon Queen, Horace Martin, and Crimson Queen, and Mr. H. Parr, gardener to F. A. Bevan, Esq., Trent Park, Barnet, made a good third.

For one vase of early flowering white variety there were seven entries, Mr. D. B. Crane being first, Mr. W. F. Fisher second, and Mr. F. Gilbert third, all staging Madame Desgranges.

Class 16 brought out no less than nine entries, Mr. Eric J. Such winning first prize. Mr. D. B. Crane was second, with a beautiful vase of Harvest Home, and Mr. J. Kirkwood third.

#### Decorative Exhibits.

These seemed fresher, richer, and better than usual. Eight competed for the hand basket of garden flowers. Mr. Norman Davis easily led, and second, Miss C. B. Cole, Feltham. Mr. M. V. Seale came third. The latter won in class 22, for a hand basket of Chrysanthemums; second, Mr. N. Davis; and third, Miss Cole. For a vase of Chrysanthemums in class 26, the leader was Mr. A. Robertson, gardener to F. J. Yarrow, Esq., Mitford House, St. John's Wood; second, Mr. F. G. Oliver, 97, Tollington Park, N.; third, Mr. T. L. Turk, Southwood House, Highgate. Six entered. For a hand basket of autumn foliage and berries the prizes fell as follows: First, Miss Cole; second, Mr. Seale; and third, Mr. A. Taylor, East Finchley.

The amateurs turned out well in their division. In the class for twelve blooms, distinct, there were three entries, Mr. A. Robertson, gardener to F. J. Yarrow, Esq., Mitford House, St. John's Wood, being first with a board of well coloured blooms, the best being Madame Von Andre, Mutual Friend, Soleil d'Octobre, Sensation, Madame Gustav Henry, and Pride of Madford. Mr. J. Childs, gardener to Mrs. Foss, The Priory, Totteridge, was second, with nice blooms of Rayonnante, Mr. A. H. Barratt, and Soleil d'Octobre; while Mr. M. Rayment came in for third place.

Class 28 was for six blooms, Japanese, distinct. Here there were four entries, Mr. A. Robertson winning first honours with a good level board. His varieties were Madame Von Andre, Mrs. J. Bryant, Mutual Friend, Australie, Madame Gustav Henry, and Sensation. Mr. J. Farrow, gardener to G. R. Peerless, Esq., Park Hill House, Clapham, was second, and Mr. J. Childs third.

The class for twelve bunches of Pompons was only represented by two competitors, Mr. T. L. Turk winning handsomely with an excellent exhibit, the best varieties being Martinmas, Alice Butcher, Miss Davis, Lyon, and Madame E. Lefort. Mr. F. Gilbert, gardener to M. N. Battenshaw, Esq., Blackheath Park was second.

Class 30 was represented by three entries, which compared favourably with the rest of the show. Mr. E. Brown, jun., Southampton, secured first place, having good flowers of Soleil d'Octobre, Mrs. G. Mileham, Lily Mountford, and General Buller. Mr. Thomas Smith, Cobbold Road, Leytonstone, made a good second with Soleil d'Octobre, Madame Gustav Henry, Mrs. White Popham, and Edith Pilkington as his best flowers; Mr. Martin Silsbury, Shanklin, Isle of Wight, being third.

#### New Varieties Certificated.

*Black Prince*.—Fine large crimson flower, golden reverse, very free, splendid habit. F.C.C.

*Nelly Blake*.—A seedling from Madame Desgranges, of a very pleasing shade of crimson, slightly taller than the parent, though identical in habit. F.C.C. Both from Mr. G. Shawyer, Cranford, Hounslow.

*Mary Perkins*.—A soft yellow Jap. F.C.C. From Mr. H. Perkins, The Gardens, Greenlands, Henley-on-Thames.

#### Medals Awarded.

The following awards were made to non-competitive groups:—

Gold Medals to Hobbies, Limited, Mr. H. J. Jones, H. Low and Co., J. Berwick, H. Cannell and Sons, and W. J. Godfrey. Silver-gilt Medals to Messrs. Cutbush and Son, H. Spooner and Sons, J. B. Coldwill, R. Forster, and E. F. Such. Silver Medals to H. Deverill, J. Peed and Son, and G. Shawyer.

#### Non-competitive Exhibits.

Mr. W. J. Godfrey, Exmouth, Devon, contributed an interesting display of his last year's novelties, including Godfrey's Masterpiece, Exmouth Crimson, Mafeking Hero, and Edward VII, all of which were large, deep, and good. A capital new seedling was seen in Britannia, a rich canary yellow. He also staged a number of good decorative sorts, with Carnations in the centre

of the group, and plants, *Fuchsia triphylla* var. Marg. and F. t. Furst Otto, both good things, the former deep crimson, the latter pink.

Messrs. Hobbies, Limited, Dereham, produced a truly autumn display of Dahlias and Roses, the former predominating, and the Cactus section occupied the premier position, the arrangement being light and attractive. The most conspicuous varieties of the latter being Loogaen, Galliard, J. W. Wilkinson, Fred. Cobbold, Mrs. E. Mawley, Winsome, Gabriel, Lottie Dean, Mrs. J. P. Clarke, Khaki, and Alpha. The Pompons comprised a good general stock, and the Roses the best of the autumn flowering varieties.

From Mr. H. Berwick, Sidmouth Nurseries, Sidmouth, Devon, came a good collection of Apples and Pears, the former displaying more colour than has been apparent during the present season, the most noticeable being The Queen, Keswick Codlin, Lane's Prince Albert, Emperor Alexander, Peasgood's Nonesuch, Gascoigne's Scarlet, and Bismarck. The Pears were undersized, but a representative display was staged.

Messrs. Hugh Low and Co., Bush Hill Park, Enfield, arranged a table of Liliiums, Begonias of the Gloire de Lorraine type, some beautiful Crotons, and a few Dracænas with Palms and other appropriate plants, the whole forming a pleasing group. Messrs. Hugh Low and Co., Bush Hill Park, also contributed a good display of Apples tastefully arranged with a few flowering Ericas, Oranges in fruit, and Palms.

Mr. H. J. Jones, Ryecroft Nursery, Lewisham, arranged an exhibit of Chrysanthemums, Palms, and autumn flowering plants grouped in three bays in his well known style; in the Chrysanthemums the chief varieties were George Laurence, Miss Elsie Fulton, Mrs. Greenfield, Miss Emma Fox, Mrs. G. Mileham, Nellie Bean, Frances Connor, and a collection of Asters, Zonal Pelargoniums, early flowering Chrysanthemums, arranged tastefully with Palms, Bamboos, and Ferns.

Messrs. W. Cutbush and Sons, Highgate, contributed a large display of Dahlias, which consisted of Cactus, Pompon and single varieties, all the most modern forms being represented, Messrs. Peed having Begonia blooms from the open air.

Mr. J. B. Coldwill, Sidmouth, Devon, staged a bright collection of Apples, Pears, and Tomatoes, all exceedingly clean and handsome. Messrs. H. Spooner and Sons, Hounslow, had also a creditable fruit display, embracing typical samples of the best varieties. Mr. H. Deverill from Banbury, brought a charming assortment of Zonal Pelargoniums staged in bunches; and Messrs. Cannell and Sons had their beautiful Cannas. A group of Chrysanthemums came from Mr. R. Forster, of Nunhead Cemetery, and another exhibit of early flowering sorts from Mr. Eric F. Such, Maidenhead.

#### Deverill's Prizes for Vegetables.

Class A: Six of Banbury Tankard Onion.—Mr. J. Bowerman was first, Mr. R. Lye second, and Mr. H. Folkes third.

B: Six of The Autocrat ditto.—Mr. W. Grithlam, of Newbury, was first here; second, Mr. T. F. Hakey, of Hemel Hempstead; and third, Mr. J. Bowerman.

C: Twelve of Ailsa Craig.—Mr. H. Folkes led, Mr. Bowerman was second, and Mr. N. Kneller third.

D: For six of the same variety.—Mr. Folkes again wrested premier honours to himself, and second, Mr. R. Lye. Class E, for the best dozen of a selection, Mr. Folkes beat Mr. Lye.

F: For six Exonian Leeks, Mr. E. Beckett was foremost; second, Mr. Folkes; and third, Mr. C. Brown, Abbots Langley. There were six entries.

G: Three lots of Carrots (Exhibition Scarlet) were on view. Mr. R. Noller, White Lodge, Oxford, led; Mr. R. Lye, second; and third, Mr. F. Allford, Earlestone, Devizes.

H: Five sets of twelve Middleton Park Favourite Beet were staged. Mr. R. Lye was leader; second, Mr. Folkes; and third, Mr. E. Beckett.

In class L Mr. T. A. Beckett beat Mr. W. Woodcraft, Banbury.

J: For the best dozen fruits of Deverill's Glenhurst Favourite Tomato, four entered. Mr. E. Beckett was first, Mr. J. Bowerman second, and Mr. H. Folkes third.

K: For a collection of eight kinds of vegetables five competitors came forward with handsome displays. The honours fell in the following order:—Mr. E. Beckett, Mr. H. Folkes, Mr. J. Bowerman, and Mr. Charles Brown. Each staged fine clean samples, and took care to place on view to the best advantage.

#### Scottish Horticultural.

The monthly meeting of this association was held on Tuesday evening, the 7th inst., in No. 5, St. Andrew Square; Mr. Comfort, president, in the chair. After preliminary business, and the election of a number of new members, a paper was read from Mr. Brown, gardener at Houston House, Renfrewshire, on "Growing of Vegetables for Exhibition." Mr. Brown's paper was a very practical one, and detailed his methods of growing the leading sorts of vegetables, which usually grace the exhibition table, with great ability and clearness. A very interesting discussion followed, and a very hearty vote of thanks was accorded to Mr. Brown. There were an unusually large number of

exhibits on the table, of a most attractive character. Chief among them was a splendid collection of early flowering Chrysanthemums in about forty varieties, embracing the best and newest of existing sorts, including Parisiana White, Mytchett White, Goacher's Crimson, Horace Martin, and a beautiful seedling, Golden Gem.

Mr. M. Cuthbertson, nurseryman, Rothesay, exhibited a beautiful collection of new varieties of Cactus Dahlias, and a number of beautiful autumn blooming herbaceous plants, including Harpaliums, Montbretias, Tritomas, Lobelias, &c. Mr. Todd exhibited from his garden at Musselburgh a very beautiful vase of Lady Fitzwygram Chrysanthemum, and a handsome vase of Roses, remarkably good for the season, chiefly Caroline Testout and Ulrich Brunner. Mr. Todd had also Goacher's Crimson Chrysanthemum in fine condition, and splendid giant Mignonette, with a grand collection of Sweet Peas in over thirty varieties, which were marvellous for the late period of the season. The collection embraced all the leading and newer sorts. These were awarded a cultural certificate and a special vote of thanks.

Mr. Johnstone, of Hay Lodge, exhibited a beautiful plant of Tillandsia. Mr. J. C. Young, Fettes Row, exhibited a beautiful bronze sport from Casimir Perier Chrysanthemum, which was awarded a first class certificate. Mr. Dunn, Dalkeith, exhibited Amaryllis Belladonna in beautiful condition, from the open air. A vote of thanks was accorded to the exhibitors.

#### Royal Caledonian Horticultural.

The following is a letter from the president of this society, which has been issued as an appeal to the Scottish people who are lovers of the garden, or professional gardeners, to join the ranks of, and assist the society:—

Kennet, Alloa, September, 1902.

"Sir or Madam,—I beg the favour of your reading the short statement I enclose. It puts in a concise form the aims of the Royal Caledonian Horticultural Society, of which I have the honour to be president. The committee are most anxious to secure an increase in the membership of this society, and as a national institution it seems to me to have great claims upon the consideration of all Scotsmen who are interested in horticultural matters. I venture to express the hope that you will allow your name to be enrolled amongst its members.—I am faithfully yours,

BALFOUR OF BURLEIGH."

"This society was founded in 1809 to encourage and improve the cultivation of fruits, flowers, and vegetables in Scotland, and the records of the society show good work done. It is nearly 100 years old, and may be said to be the parent of all other such societies in Scotland. The society holds two or more shows each year in Edinburgh, at which exhibits from all parts of Great Britain and Ireland are received free; also from the Continent and America. The shows are largely competitive, but the trade also exhibit well. There are thus brought before the Scottish public and horticulturists the best examples of the produce of the gardens of the United Kingdom, and also new and little-known plants. Even as an educational institution the society has very strong claims to be supported. The educative feature is kept in view in the preparation of the prize schedules, and competent judges have declared that the society's exhibitions are among the best of their kind. To maintain the society's usefulness it is necessary to have a strong membership. The council rejoice in the rapidly increasing strength of the sister society in England (the Royal Horticultural), but, at the same time, desire to take this opportunity of soliciting and urging Scottish people to support also their National Horticultural Society. Those desiring to become members may be enrolled on application to the secretary on any of the following conditions:—Two guineas, one guinea, or half-a-guinea annually. These annual subscriptions may be commuted by one payment of twenty guineas, ten guineas, or five guineas respectively." The name and address of the secretary and treasurer is P. Murray Thomson, S.S.C., 5, York Place, Edinburgh.

#### Liverpool Amateur Gardeners.

There was an excellent attendance of members at the monthly meeting, held in the Common Hall, Hackins Hey, on October 2. The large hall was devoted to a capital assortment of fruit, flowers, and vegetables; the cut blooms for the special prize being won by Mr. Robins with a collection comprising herbaceous plants, Roses, &c., fit to grace any table. Some capital Apples and Pears came from Mr. R. Muir, of Formby. Mrs. Stevenson had the best table plants—a Chrysanthemum in bloom, a splendid "Phenomenal" Fuchsia, 7ft high, in a 7in pot, and a basket containing well coloured Tomatoes and two bunches of Grapes, grown in a roof greenhouse in the midst of the city. For the latter she received full points and certificate, and rightly so, for it is the result of perseverance and good work. Mr. Thomas had good Apples and vegetables, and Mrs. Morris the special for a plant in bloom.

In the lecture room, the chair was occupied by Mr. Ellison,

who introduced Mr. R. Pinnington to give his lecture, entitled "Seasonable Hints." Mr. Pinnington, who spoke entirely without notes, gave a capital object lesson on the right and wrong system of fruit tree pruning, also the evils resulting from deep planting and the lack of moisture at the roots in early autumn and spring, stating cases of failure which were alone attributable to the want of root-pruning. Useful advice was tendered in the matter of storing and preparing Pears for exhibition, and especially recommended the cordon principle of growing. Dealing with Roses, he advised amateurs to go over the trees and to remove all their useless shoots at the present time, as it tended to assist the growths left. Liliums he advised being purchased as early as possible, potted in a good sound loam, leaf mould, and coarse silver sand, the pots to be well drained, filled three parts full, plunged up to the rims in ashes in frames, and sheltered from severe frosts. By this means scarcely any water would be required until growth commenced, when top-dressing would be necessary.

**Cordon Gooseberries.**

He was most severe on the use of too much manure being mixed in the bulb compost, preferring to give liquid stimulants when root action was good, and condemned the use of too large pots for single Hyacinth bulbs. Mr. A. W. Ardron spoke in high terms of the lecture, and Mr. Cangle seconded, Mr. Pinnington afterwards answering several questions.

### **CORDON GOOSEBERRIES.**

Gooseberries may be grown as standards, espaliers, wall-trained, or bush specimens; but there is no form by which finer fruit is obtainable than the single cordon. Gooseberry cordons can be grown 6ft to 8ft long, and have the whole length of the shoot covered with fruit. It is doubtful if there is any kind of fruit-growing by which so much can be secured from a given space, unless it be cordon trees of some other fruit. Mr. Molyneux once estimated in these pages that an acre of ground planted with Gooseberries on this system would yield £135, and this not one year in three or four, but three years out of every four, and a fair crop the fourth. Cordons are usually 1ft to 2ft long when bought; they can be trained horizontally or erect.

East and west walls are the best for them, especially the latter, as in this aspect the sun does not shine upon them when the frost is on the bloom, and early fruit can be obtained. Cordons may also be planted on wire trellises running east and west, where they will be found to grow and fruit well. They may be planted 9in to 1ft or more apart. The ground should be previously well enriched with basic slag or farmyard manure. There is no fear of their running to wood; the stronger the wood the better the fruit. When Gooseberries have been in bearing a few years they are much benefited by having an inch, or even 2in of rich soil placed over their roots in place of the old soil, which may be removed. Ripe Gooseberries may be enjoyed from the middle of June to the middle of September by cultivating early sorts like Golden Drop, Early Green Hairy, and Wilmot's Early Red on a south-west wall; and late sorts like Ironmonger and Warrington Red on a north wall.

### **Fruit Forcing.**

#### **PEACHES AND NECTARINES: EARLIEST HOUSE.—**

The trees are now leafless, and should be overhauled for pruning, dressing, and readjustment of the growths. Where due regard has been paid to disbudding, preventing overcrowding, and removing the useless growths after the fruits were gathered, very little pruning will now be required. Weakly and unpromising branches, however, may often be advantageously cut out in favour of sturdy, short-jointed growths, and unduly long shoots be shortened so as to originate vigorous ones from them at the proper place for covering the trellis evenly with bearing wood. The house should be thoroughly cleansed, woodwork with carbolic soap, water, and a brush, glass with clear water, and the walls limewashed, with a handful of sulphur to a pailful, the sulphur being first formed into a paste with skim milk. The trees should also be washed with an insecticide, those advertised being excellent for the purpose, or paraffin emulsion,  $\frac{1}{2}$ lb to three gallons of water, adding 1oz of sulphide of potassium (liver of sulphur) as a fungicide, applying with a brush, and taking care not to dislocate the buds. Likewise the border needs attention, removing the mulching or loose surface soil, pointing over very lightly, and supplying fresh loam, but not covering the roots more than 2in. About a quart of some approved fertiliser, such as those advertised for fruit trees, may be mixed with a barrow-load of loam, to which a fifth of well rotted manure has been added, and the manurial elements will get diffused through the soil by rains or watering, and be available as food when the trees start into growth. The roof lights may remain off until late November or the approach of severe weather, frost and snow sometimes interfering with their replacement.

**SUCCESSION HOUSES.**—The foliage in these is quite green, being later in being shed than in hot seasons. The growths, however, are firm, and the buds quite prominent enough in the axils of the leaves. Too much air cannot be admitted, but it is necessary to reduce the ventilation on cold nights, or close the house in case of severe frost, which may cause the sudden collapse of the foliage and prejudicially affect the buds. Any trees that are unsatisfactory should be root-pruned or lifted as soon as the foliage is matured sufficiently, or when it gives indications of falling. In the case of young trees making a late growth it will be advisable to form a trench at a distance from the stem equal to almost one-third the spread of the branches, detaching all roots down to the drainage, leaving the trench open for ten days or a fortnight, when it may be filled firmly; this checks growth and contributes to the maturity of the wood and buds. It also encourages the formation of fresh rootlets, insuring a fibry formation of them, which will decidedly benefit the setting and stoning of the fruit, as the tree is better nourished provided it is present in the soil. Care must be taken not to allow the soil to become dry in the part undisturbed.

**LATE HOUSES.**—The wood which has borne fruit may be cut out and thinned where too crowded. The structure may be kept rather close by day when there is sun, throwing the house open at night, which will assist the wood to ripen and concentrate the tree's energies on the buds. In cold localities a gentle warmth in the pipes in dull weather will facilitate the ripening process, but it must be accompanied by a free circulation of air.—**ST. ALBANS.**

**HOUSING OF RIPE GRAPES.**—Hamburgs and all thin-skinned varieties of Grapes require frequent examination for the removal of decayed berries. Damp being their great enemy, it should be prevented by a circulation of air constantly, the employment of fire heat in daytime, accompanied by free ventilation, allowing the house to cool before night, and admitting air the following morning sufficiently early to allow the atmosphere to heat gradually, and thus being warmer than the berries, moisture will be deposited upon them.

### **Kitchen Garden.**

**LIFTING ROOT CROPS.**—The prevalence of brisk, dry weather affords an excellent opportunity for lifting and storing the crop of Carrots, Beetroot, summer Turnips, and late Potatoes. It is important that the roots, also Potatoes, be thoroughly dry before storing, hence it is advisable that no more be lifted in one day than can be removed under cover by evening. As much of the tap root as possible must be secured with the Beetroots, and the tops should be twisted off about 2in above the crown, which prevents bleeding. The tops of Carrots may be cut off to within an inch and a half of the fleshy crown, and little or

none of the tap root preserved. Treat Turnips similarly. Very dry sand, soil, or wood ashes are excellent materials for storing roots in, but the place of storage must be dry, or they will absorb the moisture to a great extent. Store Potatoes on a wooden floor, and cover with clean, dry straw. Carrots, Turnips, and Beetroot may be placed in layers between any of the dry materials above referred to.

**OUTDOOR TOMATOES.**—Any Tomatoes still remaining outdoors ought to be cut, stem and all, and placed in a dry, warm position under glass to fully ripen. Many of the small, green fruits will not colour, but those that are tinged when the stems are cut will gradually do so under the influence of artificial warmth.

**LIFTING ENDIVE AND LETTUCE.**—Unless favoured with a sheltered, warm spot some of the fully grown plants may be lifted and placed in frames, though the same object will be attained if glass lights, elevated on bricks or blocks of wood, are used to cover them. Protection at the sides is not needed. Cold will not harm them, but continued wet causes the hearts to rot.

**BLANCHING ENDIVE.**—There are several methods of blanching, without which Endive is of little practical use. Those varieties having sufficiently long outer leaves may have these drawn together over the centre, and tied together at the points. This will help the hearts to blanch, especially if large pots are placed over, with the hole stopped up to exclude light entirely. The curly, short leaved varieties may be blanched by laying a slate or tile over the plants, placing it on them when the plants are dry.

**LEEKS.**—Many of the most forward plants have advanced to a sufficient size when they may be earthed up so as to thoroughly blanch the stems as high as possible, at least as high as the bottom leaves. A soaking of liquid manure may be given before the final earthing, as well as to later plants still progressing in growth. Shorten the straggling ends of all the leaves, cutting the basal leaves closer. The finest Leeks are grown in trenches, in which they are readily fed and soil added.

**PARSLEY.**—It is important to have a good supply of Parsley during the winter and early spring months. Plants from an early summer sowing should now be in good condition, being furnished with luxuriant, short-jointed leaves. Some of the strongest of these plants may be lifted and potted, standing the pots in a sheltered position outdoors until later in the year, when place in a cool house. A Parsley bed may often be sufficiently protected by laying lights over when the weather sets in hard and frosty, usually in December. The bed of young plants from an August sowing should be kept clear of weeds and dead leaves. Severe thinning of the plants which are small is not necessary at present.

**DUTCH HOEING.**—The soil between the rows of Spinach, autumn sown Turnips, Lettuce, Onions, and Cabbage should be freely hoed over, so as to maintain a fresh, sweet surface, and to destroy seedling weeds. The hoeing admits warmth and air, thus promoting steady and healthy growth.

**POTATOES.**—The prevalence of disease among the crops in various parts of the country will necessitate extra attention being paid to examining the tubers from time to time. Although the greatest care may have been expended in picking out affected specimens at the time of storing, it is wise to look over them again, so as to maintain the stocks of the various varieties as sound as possible.—EAST KENT.

### Meteorological Observations at Chiswick.

The days have been dull and dark, with cold biting north-easterly winds.

\* \* All correspondence relating to editorial matters should be directed to "THE EDITOR," 12, Mitre Court Chambers, Fleet Street, London, E.C. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense.

**BOOK WANTED (J. D.).**—It would be entirely unnecessary to publish a book on the subject of grouping Chrysanthemums and that only. Any gardener with experience, or without experience, but with good, sound judgment and a perception of what is tasteful, can arrange groups. We have given illustrations through the Journal of good groups. We will endeavour to furnish a descriptive article soon which may be of use in affording you suggestions.

**GRAPES AND LEAVES FOR IDENTIFICATION (A. A. T.).**—The Grapes are only about two-thirds the size in berry of Madresfield Court, and the leaves are not rugose, as that variety is. It certainly is a late Grape of first-rate quality, and we think West's St. Peter's, though the foliage is large for this variety, but that may be owing to the vigour of the Vine, and the veins of the leaves are not red. The leaves of West's St. Peter's usually die off yellow, but sometimes they are highly coloured, of which we notice the latter in one of your leaves, the other being without traces. Certainly Madresfield Court would not so change from the house being kept too hot; indeed, it would ripen about same time as Muscat of Alexandria and Alicante.

**SCALE INSECTS ON PALM LEAF (T. L.).**—The long narrow coccid (scale) has been designated the black thread scale (*Ischnaspis filiformis*, Douglas). The species was first discovered in this country by Mr. Douglas in 1887, since when it has been gradually on the increase, and now occurs in many parts of the British Isles. Unfortunately, it is a very pernicious pest, and most difficult to destroy in the adult stage. In its young stage, however, it is comparatively easy to kill, and frequent sponging, spraying, or dipping should be resorted to. The ordinary paraffin and soap emulsion has met with the best results. (See Journal Royal Horticultural Society, vol. xxiii., pp. 219-262.) Nothing but the hydrocyanic gas treatment will kill the old scales, which are insoluble in potash. The Palm leaf is also attacked by the so-called black seed scale (*Ceraataphis lataniae*), easily distinguished by the pure white fringe; but this is a true aphid, although it bears a striking resemblance to a coccid.

**FORMING LEAF MOULD (Cantab.).**—The leaves now falling should be gathered into a heap, a place being selected where they can be spread rather thinly, so as to prevent any excessive heating by fermentation. The whole should be turned over occasionally so as to expose all parts in turn to the influence of the weather and air. Where air cannot reach leaves that are of a somewhat hard, dry nature, such as Beech, Oak, and Spanish Chestnut, their decay is exceeding slow unless there are softer textured leaves intermixed to hasten decomposition. Water may be applied artificially for the purpose, but it never has the same effect as rain, and if a large heap is made this latter cannot penetrate far into the interior. The leaves should be collected free from sticks and bark if possible, as these are liable to encourage fungoid growth, which may render it more or less useless for plant cultivation. The time taken in reducing leaves to a mould or fine soil depends greatly on the amount of turning over and other attention devoted to the preparation. Much may be effected in the course of a year, or even less, but the quality is usually better if a longer time is allowed.

**SAVOY STEMS AFFECTED WITH CABBAGE FLY AND CLUBBING (J. R.).**—The attack of the cabbage-fly, *Anthomyia brassicae*, of which we found some maggots, has no doubt been greatly accelerated by heavy manuring; indeed, the maggots live in dung as well as feed on Brassica tribe underground stems, and the season being a wet one has probably favoured the maggots—at any rate, your specimens show the attack to have been severe. The clubbed root is due to attack of club-root fungus, *Plasmodiophora brassicae*, and for both the root-maggot and clubbing a dressing of gas lime is the best preventive. It should be applied as soon as the crop is cleared off the ground at the rate of 2½ to 5 tons per acre, and should be fresh from gas works, spreading evenly, and left on the surface a month or six weeks before ploughing in. If cleared in autumn the heavier dressing may be given, and if intended as a preventive on new ground the lesser amount may be applied in late winter

or early spring, leaving at least a fortnight on the surface before ploughing in. Instead of using the manure you name, we advise an artificial dressing at seed-time of 3 cwt superphosphate mixed with 1 cwt of bonemeal; top-dressing, after singling out, with 2 cwt of nitrate of soda per acre mixed with 3 cwt of salt. The land evidently lacks lime, or is surfeited with the animal manure.

**NAMES OF FRUITS.**—*Correspondents whose queries are unanswered in the present issue are respectfully requested to consult the following number.* (T. J. R.).—Grape, 5, Black Morocco. Pears—1, Clapp's Favourite; 2, Williams' Bon Chrétien; 3, Jalousie de Fontenay; 4, Emile d'Heyst. (J. D.).—1, Allington Pippin; 2, Hornmead's Pearmain; 3, Emperor Alexander; 4, Red Streak; 5, Ribston Pippin. (A. T.).—1, Lady Sudeley; 2, not recognised; 3, Annie Elizabeth. (B.).—White Muscadine. (L. M.).—1, Tower of Glamis; 2, Mrs. Gladstone; 3, Worcester Pearmain; 4, Bramley's Seedling.

**NAMES OF PLANTS.**—*Correspondents whose queries are unanswered in the present issue are respectfully requested to consult the following number.* (Hutton).—*Calceolaria mexicana*, not nearly largely enough cultivated, a pretty little border annual. (T. J. R.).—1, the Grey Poplar (*Populus canescens*); 2, *Mesembryanthemum* sp.; 3, *Mesembryanthemum cordifolium variegatum*; 4, *Veronica Andersoni* variegata; 5, *Centaurea candidissima*; 6, *Polemonium caeruleum* variegatum; 7, *Cornus alba*. (T. J. R.).—1, *Itea virginica*; 2, *Juniperus chinensis* var.; 3, *Cupressus (Retinospora) Lawsoniana*, var. *erecta-viridis*; 4, *Rhus typhina*; 5, *Biota orientalis* var.; 6, *Hibiscus syriacus*; 7, *Berberis nepalensis*; 8, *Cupressus obtusa* compacta; 9, *Juniperus chinensis albo-variegata*; 10, *Pernettya mucronata* (type). (Water Weed).—The aquatic state of *Callitriche autumnalis*. (J. B.).—1, *Tilia europæa*, or common Lime; 2, *Catalpa bignonioides aurea*; 3, *Populus alba foliis aureis*; 4, *Sambuca racemosa tenuifolia*; 5, *Ulmus campestris viminalis* variegata. (Ellen).—*Kerria japonica* fol. var. (J. T.).—1, *Crataegus pyracantha*; 2, *Rubus odoratus*; 3, *Lælia majalis*; 4, *Aster Lynosyris*.

## An English Journalist on American Farming.

We do not know whether any of our readers ever have come across articles from the pen of John Foster Fraser. Lately he gave us a series of letters from Siberia; now in the interests of a leading provincial paper he is "doing" America, and doing it well, too. We believe Mr. Fraser hails from, or has passed many years of his life at, St. Oggs on the Floss. Readers of fiction will know what town and what river we indicate, and there at any rate he would, if he had eyes to see, observe in the neighbourhood some very typical English farming. Mr. Fraser has a great respect, nay admiration, for the American farmer, who really is not a pure American at all. Scotch or Scandinavian blood goes to make up the pedigree of the farmer, and he is a go-ahead fellow—hard working, and far-seeing, and a believer in the help of machinery to the last detail. It is wonderful what a feeling there is all the world over about the sons of stern Caledonia; they make headway where others starve, but a Scotch-American mixture can lick creation!

We do not quite grasp the vastness of American agriculture. We take the Eastern States; where, according to Mr. Fraser, agriculture is getting played out, and the farmers of the Middle States are gradually going further N.W., or crossing into Canada, and making a great settlement there. Montana, Nevada, and Idaho are receiving a great overflow. Just look in the map and see how far west these States are, and then consider for a moment how large the whole area of the States is—nearly the size of Europe. We lump it all under the words United States but forget how much those words cover.

The further west you travel, the larger the farm. The average size of the five million farms is 146 acres. The ideal size is 250 acres, and one of the mammoth farms of the west is 500,000 acres, of which 8,000 acres are sown with Wheat. Another farm with a Wheat field of 62 square miles! We

wonder how many self-binders will be turned into that "piece" at harvest time. We are often bothered by delay at the stations for railway waggons to convey our produce to the purchaser. It is simply a question of waiting a day or two. What should we say at having to burn our produce because the railway companies were unable to deal with it? Mr. Fraser has a great deal to say of James Wilson, who, from an Ayrshire herd laddie, has risen to the onerous and honourable position of Minister of Agriculture. Here again is the Scottish element. He, being a practical farmer, is the man in whom the farmers trust. We did not know that so far back as 1862 the American Agricultural Department was started, and how far ahead of us is Brother Jonathan. It makes us rather gasp when we read of the work undertaken and done by this Department. Evidently there is no grudging of funds: £100,000 per annum, and, besides that, most of the States have each their own colleges, which also receive each £5,000 per annum.

There is a college in Minnesota with between three and four thousand pupils, and each college has a vast tract of land for culture and experiment. There is nothing like starting free from prejudice. Mr. Fraser says the men of the Eastern States are not much for scientific farming; they have too much bias towards old ways and old customs. It is the new man, the western man, who is ready to listen, to read and to learn. Happily he has no end of opportunity.

Here is an example of some of the work done by the Department at Washington. Publications were issued, in number, 616, and of these publications, 8,000,000 copies were distributed. The "Year Book," which is a big volume, and one we have mentioned in this journal, is widely disseminated, as each senator and representative has 15,000 given to distribute among his constituents. Last year this office received and answered something like 300,000 letters which required information.

Unless the Englishman, says Mr. Fraser, is inclined to forget England and English ways, he will make no headway as a States farmer. He must come prepared to work hard and live hard, and to move quickly. Old slow methods won't do there. He requires the nervous unrest of the typical States farmer, a man who is only a labourer once or twice removed. A well educated Englishman of adaptive habits will beat the Yankee, for his education soon begins to tell.

The advantages of the N.W. and Canadian farming lie partly in the cheapness of the land (uncultivated land being obtainable for 1s. 8d. per acre, and cultivated for from £3 to £5 per acre), and also because, so far, there are no difficulties in connection with the squeezing by trusts and the railway companies. These amalgamations of buyers are a sore trouble to the small dealer, as they can dictate the price of grain for the season, and also control the railway companies, and they practically crush the small man out of existence.

Possibly some of our readers have seen pictures of the grain elevators in the great Wheat-growing districts. Talk about national granaries! Here we have the very thing, though really made for another purpose. Imagine a store that will hold 3,000,000 bushels of grain. The corn can be taken from the trains into these store-houses at the rate of 10,000 bushels an hour, and the big cranes can load the grain into vessels at the rate of 25,000 bushels per hour! Such is American contrivance.

To go back to Mr. Wilson. He has not at present the opening or closing of Argentine ports or Canadian live-stock on his brain, nor the milk and butter standard. He wants to do something for the schoolboy, the farmer of the future. He wants to start the lads at gardening, thinking truly that once he gets them interested in the cultivation of the soil, they will want a wider area than is afforded by a small garden. He will see that seeds and plants and trees are found. The experimental farms will come after, and we rather thank they have been pushed too much to the fore and the simple method ignored. There has been the effort to run before the pupil could walk.

There is a strong veterinary side in this Agricultural Department, and a strict watch is kept to try and ensure a clean bill of health, and only last year a Bureau of Plant Industry was created, and investigations started with respect to disease in cotton, fruit, timber, and in the evolving of new varieties which will be disease proof (at least for a time)—the brackets are ours. How often have we been assured that a new Potato has arisen which is perfectly disease proof? But, sooner or later, in spite of all asseverations to

the contrary, do we find it go the way of all Potatoes. And thus our savants will always find their work cut out; they may cross, and breed, and hybridise, but they will never reach absolute perfection. New complaints, and new pests seem to arise, the result, shall we say, of our over-civilisation?

The American farmer has one great pull over us: it is a point that touches us much at present. Under usual circumstances he can thresh his crops from the field. There is no intermediate process of stacking and thatching. This means much saving of time and labour. It is only during the most exceptional season we dare venture on such a process here. We think, too, we can grow a little more weight per acre, but we cannot boast much of betterness of price.

We wish Mr. Fraser would give us another article on American stock-raisers, we do not live by bread alone. He might leave out the pigs, but remarks on well known shire studs or shorthorn and Hereford herds, would be most welcome.

Mr. Fraser makes one statement that obliges us to stand still and stare. He says, "We had no Minister of Agriculture here until we had ceased to need one. England had then ended her career as an agricultural country." We had still a sort of feeling that we as a nation were to the forefront in agriculture, but it appears that our sun has already set. Where, we should like to know, will be found better farming than here? Where such pure-bred stock of all descriptions? Why! we are the pedigree stock breeders for the world; and Mr. Fraser admits himself, that our farmers are a very different class of men from their prototype in the States. We know, as corn raisers we are taking somewhat of a back seat, but the majority of people don't clearly see how this is. We still can grow more bushels per acre than any other country, and it is not our fault that the acreage is limited. We are girt in by our sea-walls, and ploughing the sea-shore has never been a profitable pursuit, even if it were feasible. We can still teach our Yankee friends a thing or two.

### Work on the Home Farm.

Another fine week has seen the harvest completed, and a capital finish it has been. The belated ones have been the most fortunate, and have a large portion of their Corn in fine threshing condition, whilst the "hurriers" have little that they can knock out for some time—a case of the hare and the tortoise.

Threshing is being very heavily prosecuted, and markets are glutted; 27s. is the top price for Wheat, and fair samples may be bought at 26s. There are plenty of Oats at 17s., and 29s. 6d. is so far the top price for Barley. Though prices are so disappointing, the yield still compensates by showing a bright lining to the cloud. One farmer has threshed 180qrs of Oats in one day and a half, and another 66qrs of Wheat in one day. Not bad, those!

Farmers seem more inclined to thresh than thatch, and where they are thatching the work is frequently done in a very inartistic manner; the pegs are put in with little care for regularity, and much more thatch than necessary appears to be the rule to be followed; but many of the stacks are so unsymmetrical that no thatching, even of the neatest, could make them look well. Some must have been put up by moonlight, as there is no other way of accounting for their peculiar shape. A farmer who can have six stacks in his yard all differing greatly both in form and size must have an intentional bias against uniformity. We do like to see some sense of proportion between height and width, and would never imitate either Mushrooms or mill chimneys.

It has been fine for dragging fallows, but too dry for ploughing lea. It is curious that after what has been considered a cold and wet season we have difficulty in ploughing for Wheat. The land is certainly surprisingly hard and dry. Very few Potatoes have yet been lifted, and they have gone direct to market. Farmers have no straw for Potato storing until they thresh. The fields show every appearance of having attained ripeness. We are retaining the services of our Irish labourers to do the necessary picking, and we must now go ahead. October is late for hay making, but we yesterday saw a fine second crop of Alsike and Rye Grass being mown down. The tenant of the field must be a bold man, but there certainly is a prospect that success may justify his temerity.

Black faced rams, especially Hampshire downs, are greatly in request, and those breeders who still require them are in a quandary, for the supply has altogether ceased as regards their own stock markets, and they are anxiously wiring to auctioneers at likely places, giving them almost unlimited commissions. The much to be desired improvement in English mutton will soon be an established fact; but why could not farmers be more ready to see what was coming.

## BARRS' GOLD MEDAL DAFFODILS

Have received Twelve Highest Awards, 1902, including **TWO GOLD MEDALS**  
Descriptive Catalogue of all the finest sorts in cultivation free.

## BARRS' GOLD MEDAL TULIPS

Have received **FIVE GOLD MEDALS** from the Royal National Tulip Society; **SILVER CUPS** at the Great Temple Flower Shows, 1900 and 1901, and **GOLD MEDAL** 1902.

Descriptive Catalogue of the finest kinds for pot culture and for forcing, and for beds and borders outdoors, free.

## Journal of Horticulture.

THURSDAY, OCTOBER 16, 1902.

### Commodities and Luxuries.

If anyone takes the trouble to dissect the various branches of horticulture, it will be seen that its make-up is composed very largely of what may be called commodities and luxuries. We may begin with those who pursue the gentle art; some do it for pleasure pure and simple, and others for profit and a means of livelihood. Our private gardener, for instance, is a luxury in the eyes of his employer. To supply the actual worldly needs of the latter he is not essential, and his business is to provide those extra comforts and luxuries which wealth can purchase. Yet I question whether gardeners are disposed to look at the matter in this light. As a class, they claim to be underpaid in comparison to other occupations not requiring the same knowledge and training, and perhaps rightly so. Again, they work under many disadvantages, and are frequently expected to make bricks without straw, like the Israelites of old, and their privileges are privileges rather than rights.

This is all true enough, and from the gardener's point of view it is not easy to understand; but it should not be forgotten that the man is a luxury. He plays but an unimportant part in the great concern of supply and demand or capital and labour, and if superfluous wealth were suddenly cut off, his occupation would be gone. The same may be said of other occupations, because if men generally were only possessed of sufficient wealth to provide for the actual needs of life, trade would at once be at a standstill; but the private gardener is attached to the person of his employer, and contributes to his personal luxuries, which could be dispensed with if circumstances demanded it, and the latter pays him as much as he can afford,

READERS are requested to send notices of Gardening Appointments or Notes of Horticultural Interest, intimations of Meetings, Queries, and all Articles for Publication, officially to "THE EDITOR," at 12, Mitre Court Chambers, Fleet Street, London, E.C., and to no other person and to no other address.

rather than as much as he may be worth. In these circumstances the question of combination amongst private gardeners, which is sometimes talked about, is absurd. Gardeners cannot put a monetary value on their occupation, when that occupation does not contribute towards the income of their employers, so the situation must be accepted as it is. When everything is considered, the difference is readily seen. Take the case of a wealthy manufacturer or coal owner. The meanest workman in the mine or factory is a unit in the combination which provides the owner with his wealth, and as such he has to be considered; but the private gardener, though his position is infinitely better, is nothing of the kind. In fact, he is not a paying concern, and could be dispensed with before the miner or the factory hand.

All the same, and luxuries though they be, I do not think that private gardeners have as much room for complaint as some of them imagine. Comfort and peace of mind are two great factors towards happiness in this life, and it must be said that many employers, the majority of them I think, study their domestic employes in this respect. Perhaps the gardener who receives 30s. per week may think he is ill-paid by the side of the artisan who receives half as much again in hard cash, but the former should also consider his perquisites. Let him reckon house rent and other items, and the fact that trade disputes, slack times, and bad weather do not affect his pocket, and he will have to confess that he is the better off of the two, luxury though he be.

The very fact that he provides the luxuries rather than the actual commodities of life, removes a load of responsibility from the life of our private gardener, because disasters through unfavourable climatic conditions, and other losses do not necessarily affect him in a direct way. Last May, for instance, we had a severe frost which did great damage to fruit and vegetable crops. Everybody suffered, the private gardener and the market gardener; but they were not affected alike. The former, in the interests of his employer, and for his own satisfaction as well, deplored the loss, but it did not affect his salary; but how about his neighbour the market gardener? To him the loss was doubly serious, because it was a question of pounds, shilling, and pence. On the welfare of those crops depended the living of the man who is employed in the commodity aspects of horticulture, and the whole or partial loss meant a difference in the profit and loss account at the end of the year. To mention another instance of similar character; a terrible storm burst over a part of Kent a few weeks ago which respected neither the fruit in private gardens nor market plantations. They all suffered alike, but with a different effect; because whereas the private gardeners will have less fruit for the kitchen and dessert table, the deficiency can be supplied by their employers without seriously affecting them; the little market man, and the big one too for the matter of that, were depending on the fruit in the orchards and plantations to bring in so much money, but in the space of only a few minutes hopes and calculations were dashed ruthlessly to the ground.

The object for which a garden is cultivated governs the methods that are employed. In private gardens certain crops are grown in certain ways to fulfil the wishes of the owner of the same, and the gardener gets into a groove suitable to the circumstances. He is dealing with luxuries, mind you, and the question of profit and loss does not closely affect him. It is when he leaves this line and takes up commercial gardening that he realises the difference between supplying one family with its luxuries and the public at large with its commodities. Many instances could be given of men who have given up private gardening, and, through their natural business capacities, they have adapted themselves to the changed circumstances, and have made not only good livings, but in some cases fortunes. But the failures must also be considered. How many private gardeners have invested their little savings in commercial horticulture, only to find out that their former training was of little use to them in the new line, and that the methods which answered in one case were out of place in another, which had to show a profit? They might have learnt the right course by experience if the funds had held out, but with these expended they had no other choice but to go back to private service. It is just a question of cutting a peg square and then trying to fit it in a round hole. The principles of horticulture may be learnt in a private establishment, but if his gardening has to show a profit the student had better

get experience in an establishment where this is done before he sets up in business for himself.

And what has been done for horticulture through the mediums of its luxury and commodity aspects? Much. Through the lavish expenditure of wealth for the sake of a hobby, and to provide luxuries for those who can afford them, the natural products of the whole world have been gathered together in these islands, and the conditions provided so that they can be grown artificially. Art has been brought to bear to improve on Nature, in the introductions of fresh forms and new varieties of plants for the same end, and not really because they were essential for the daily requirements of the community at large. Luxury plays an important part in the higher phases of gardening. The nation would doubtless exist and prosper without gorgeous Orchids, costly exotics, and new varieties of scores of flowers, but without them it would be all the poorer.

With the growth and progress of a nation, its requirements also increase. What were counted as luxuries in one generation are commodities in the next, and in horticulture this is particularly well demonstrated. Not many years ago the only Grapes in the market were the surplus produce from private establishments, and they were luxuries if only on account of the prohibitive price. But men saw money in Grapes, and now they are practically reduced to a commodity. And in order to produce them at the commodity cost, growers had to unlearn a great deal that had formed their education, and adopt other tactics. According to established customs, Grape growing was an intricate operation, requiring great trouble and expenditure; but the market man has upset the theories of the old growers altogether. He has shown that the best of Grapes can be grown in simple houses, with small borders and ordinary treatment, and by his economic methods he produces crops year by year that would have been considered impossible by the old school of Grape growers. Whether it pays is his concern, but by means of competition and a large output the price of English Grapes has been brought down to the level of a commodity.

Nor is this a solitary instance. Look at Tomatoes, Cucumbers, plants, flowers, and vegetables at all seasons, that were luxuries in our grandfathers' days, but are commodities now, and purchased for daily use by the man in the street. Indeed, apart from the personal pleasure and satisfaction there is in growing your own produce, it is questionable whether the average garden pays, and if the expense were reckoned up it is possible that it would be cheaper to buy the produce.

This can only be explained by the fact that commercial and commodity gardening is also economic gardening. The best of everything has to be produced at the lowest possible cost, and in quantities that would be impossible in a private establishment. It is from the private garden, the luxurious adjunct to the home of the well-to-do, that these various branches have emanated, the nurseries, market-growing establishments, and the rest, and owing to the various means of growing horticultural produce of all kinds the line which divides garden luxuries from garden commodities gradually grows less and less distinct. Is there a possibility also of the private gardener pure and simple becoming extinct? Some perhaps will think of the many establishments which, though they do not keep a profit and loss account, keep a "surplus produce" item which is expected to grow rather than diminish, and shake their heads with a fear that such a thing is not unlikely.—G. H. H.

#### Small Fruit Culture.

So far back as the official figures are available, it would appear that the extent of land in Great Britain devoted to the cultivation of small fruit this year is, with one exception, the largest on record, as it now amounts to 75,378 acres, or 379 acres more than in 1901. The present acreage has been exceeded only by that of 1896, when the extent of land under small fruit was returned at 76,245 acres. Inasmuch, however, as there was a continuous expansion in the acreage up to 1896, followed by a pronounced contraction in 1897, and by another continuous expansion since 1898, it appears not improbable, observes the "Times," that through some imperfection in the returns the area of the crop was over-estimated in and before 1896, and that the correction made itself apparent in the returns for 1897 and 1898. It seems likely, therefore, that the present year's acreage, which is 5,625 acres in excess of that of four years ago, is really a maximum, although the figures do not show it. Kent claims nearly one-third of the entire acreage.

**Odontoglossum Wilckeanum var. Rothschildianum.**

Our illustration of this splendid variety shows its immense size—fully 4½ in across. The ground colour is creamy-white, shading to yellow at the tips of the sepals. There are several reddish-brown spots, while on the petals this colour appears in irregular spots and blotches. The lip has a broad, whitish apex, and this is prettily fringed. It received a First Class Certificate from the Orchid Committee when exhibited at Westminster on September 2, by Norman Cookson, Esq., (gardener, Mr. H. J. Chapman), Oakwood, Wylam-on-Tyne.

**Dendrobiums: Their Growth and Culture.**

(Continued from page 305.)

*D. Farmeri* is another very pretty evergreen species from Moulmein. In this the sepals and petals are yellow with a rosy suffusion, the lip deep yellow, while the racemes are looser than those of *D. densiflorum*. *D. fimbriatum* and its variety *oculatum* are tall-growing evergreen species, bearing loose yellow flowered racemes. They are natives of the Himalayas.

*D. Findlayanum* is a peculiarly habited species, the joints much swollen at the nodes and very slender below. The flowers are whitish or pale lilac in ground colour, the lip yellow with a whitish margin. No difficulty will be found with this pretty deciduous species, which is named after a Mr. James Findlay, who discovered it in Burmah in 1867. *D. formosum* is perhaps the best known of the nigro-hirsute group, and a very beautiful Orchid. The pure white flowers are large and very handsome, the yellow stain on the lip serving the better to show the purity of the other segments. This is one of the many fine Orchids the late Mr.

Gibson sent to his employer, the Duke of Devonshire, at Chatsworth, he having found it on the Khasia Hills. But it is a widely distributed species, and plants have been collected over a very wide area.

Another lovely species belonging to the black haired section is *D. infundibulum*. This, when in good condition, will grow 30 in in length, the upper foot or so being wreathed with the beautiful pure white flowers, with a dense yellow eye to each. Grow this in the cool end of the Cattleya house; in the warmest house it is sure to be attacked by thrips. Its variety, *D. Jamesianum*, has shorter, stouter, and more erect stems, the flowers being slightly different in form. A cool and very moist atmosphere, small pans, and abundant supplies of air and root moisture are necessary for these two fine plants. *D. lituiflorum* is worthy of a place, and makes a very pretty basket plant, its pendulous stems being in spring covered with the pretty pink and white flowers.

*D. Lowi* is an uncommon and handsome species belonging to the same set as *D. formosum*, and bearing light buff yellow flowers stained on the lip with red. It comes from Borneo, and was discovered and sent home by Mr. Hugh Low some forty years ago. *D. MacCarthiae* is a very beautiful species, but with a very unenviable reputation among growers. In colour it resembles a

good form of *D. nobile*, the flowers, however, seldom opening quite fully. Probably this species will never become really well established in collections, as it is questionable whether the plants are very long lived, even in their native habitat. Treat it as advised for the deciduous group.

*D. Macfarlanei* is a pure white flowering species, known also as *D. Johnsoniae*. It is a native of New Guinea and other parts of Australasia, and has of late been much more plentiful in collections owing to importations by Messrs. Sander and Co. and other firms. It should be included in any representative collection. *D. meschatum*, and its variety *calceolaria*, is a very strong and stout grower, throwing up immense stems over 6 ft in height, that in their second year produce loose racemes of yellow flowers with deep purple or maroon blotches on the lip. These, although making a grand show, only last a week or ten days, and owing to the bulk of the plant, it is unsuited to small collections.

The well-known *D. nobile* is perhaps the finest garden Orchid in existence. Its varieties are very numerous, and it thrives in an ordinary stove or warm greenhouse as well as in the Orchid house proper. It has been used with great success as a parent by hybridists, and is quite indispensable to every collection. Besides the type, the finest of all the varieties are *D. n. nobiliss*, *D. n. Schröderianum*, the beautiful *albino*, and *D. n. elegans*. By bringing the plants on in succession, its flowering season may be made to extend for six months or more, and it is easily propagated

either by division or by laying the stems on pans of moss.

*D. ochreatum* or *Cambridgeanum*, as it is also known, has stems 8 in or so in length, and it flowers upon these in a green state like *D. chrysanthum*. Its blossoms are a bright yellow with a deep stain on the lip. After flowering it should be rested in a cool house and repotted or top-dressed when it commences to grow in spring. It is a native of India, and first flowered in this country at Chatsworth in 1838.—H. R. R.

(To be concluded.)

**The Week's Cultural Notes.**

In many small collections of Orchids, as well as in the large ones, there is a compartment devoted to flowering plants alone. This is a very good idea, as the blossoms last far longer than when the plants are kept to the growing quarters. Not always, perhaps, are there Orchids enough in

flower to furnish it properly, and other plants of an ornamental character have to be brought in. Flowering plants other than Orchids are not usually to be recommended, those having ornamental foliage being most suitable, as nothing in the whole race of flowering plants looks really well in conjunction with Orchids.

Small, well-coloured pieces of *Croton*, *Caladium*, *Coleus*, *Dracena*, *Fittonia*, *Panicum*, and *Tradescantia* help materially in brightening up a group of Orchids, and with the aid of these and some Ferns of various sizes, a few flowering specimens may be made to go a long way. *Anthurium Scherzerianum* may be admitted, as this serves to make a contrast with the usually rather sombre tints of the Orchid, and it is very lasting. Small Palms at intervals, and larger specimens to flank and back up the group are excellent, and the whole arrangement must be kept as light as possible, not arranged in a flat sloping bank, but with distinct specimens standing out here and there, the kinds varying, of course, with the season.

Just now the deciduous *Calanthes* are rapidly approaching the flowering stage; as long as the leaves are healthy and the roots correspondingly active, continue to allow the usual water supply, but as these die off, very little moisture will be needed, and as soon as the flowers are well open the water supply may as well be

**Odontoglossum Wilckeanum var. Rothschildianum.**

discontinued entirely, as the roots are usually dead by this time. This refers, of course, to *C. vestita* and *C. Veitchi* and their hybrids and varieties, not to such as *C. Turneri* and *C. oculata gigantea*.

*Thunias* should by now be entirely at rest, and may, if room is scarce, be shaken clear of the compost, labelled, and hung up in small bundles in a warm house. Although this treatment may seem rather rough, it is much more to the taste of the plants than being shifted about from pillar to post in cool draughty houses. The stems themselves contain all the stored-up energy; the roots are dead, having finished their work, and a new set will be evolved next season.—H. R. R.

## Mostly Irish.

"Season of the sere and yellow leaf." What a powerfully poor description of autumnal glory! Surely that writer was colour blind to an *embarras des riches* the grand old artist flings off the palette in bold smudges, from pale chrome to intense crimson. Yet fair, but fickle, mistress, all thy inimitable blarney cannot atone for a season's misdeeds and shortcomings. From such time as "rough winds shook the darling buds of May" low mutterings arose till now, at Corn reaping and fruit gathering, including the noble tuber, they have swelled into growls both loud and deep. Still we escaped that hailstorm of which our papers told us as occurring in Kent, leaving hail on somebody's lawn a foot deep. We wondered what sort of a foot the measurement was taken with; whether it was a lady's number three shoe or a good, honest, perpendicular twelve inches. Verily, hail a foot thick is hard to gulp down. Are there, ahem!—are there any lineal descendants of Ananias over there in the reporting line? Anyway, we cannot compete with that in Ireland, although cold nights and stormy days prevailed till mid-September.

One of the Gunnersbury boys called in—all smiles. "A fortnight's holiday." "How's all at home?" (That charming home at Straffan, in Kildare.) "Oh! six degrees of frost this morning" (September 13). Condolences, of course. "Yes, but everything was blackened previously, and all starting into growth again." More condolences, cheapened by the fact that, as yet, frost of no degree has reached the seaboard of Dublin. We do not dispute the Straffan record, for there everything, even the commonest thermometer, must be, like Cæsar's wife, above suspicion. Experience, too, has proved the Kildare climate to be a trying one; moreover, we know the Straffan recorder of old, having been there more than once when there was "nothing to see," and found ample to make one say, "Oh! Straffan in Kildare with all they faults I love thee still." If there is one thing more than another that Straffan is famous for, and it is just a question whether there is, then that one thing is Daffodils, and though miles away, and months out of season, the bulb number of "Our Journal" brings the last view of them back in a flash. There they are—here, there, and everywhere; all over the place; beds borders, and lawns. Such blooms! Such foliage! Such patches of seedlings springing up in the damp, mossy grass! That although Rush produces such Tulips as cannot be excelled, if equalled, and that is doubtful, in the British Isles, or anywhere else, the Straffan Daffodils seem to beat the Rushians by points.

Never did the Botanic Gardens of Old Trinity (Trinity College, Dublin) look fresher and brighter than when seen in the evening of an August day. Plenty of rain suits this side of Dublin city. As a special favour the Water Lilies were wide awake, hadn't closed an eye, and one hardly knew which to admire most. The rich, bright red *N. Ellisiana*, however, is probably the most striking, but huge golden eyed *Chromatellas*, laying over sideways to display their charms were very captivating. *Yucca gloriosa plicata* bore dense spikes of copper tinted buds opening out into solid, waxy-looking blooms; and nice were the large flowers of *Lilium Browni* with purple banded backs. It is the home of curios in plant life, amongst which *Helleborus lividus*, sent or brought to Mr. Burbidge by a lady from Majorca, was pointed out; also *Haloagis alatus*, first cousin to a Gunnera; *Coronilla securigera*, the Hatchet Plant with yellow blooms which goes to sleep; *Hyoscyamus perennis*, the Perennial Henbane, very pretty and very singular;

*Hypoxis hemerocalloides*, a woolly budded South African with yellow blooms, *Crinum*-like foliage, and twisted, triangular stems; and a host of things which would be passed over by the man in the street failing those patient and interesting explanations the kind host is ever ready to give. Thicker and thicker do the plants stand in the houses; houses made elegant and attractive by nearly every creeping and climbing thing that grows. In spite of asking, one does not quite know how Mr. Bentley, the foreman of this department, smart as he is, manages to keep all in such order; but, as the Gunnersbury boy said, there are not many chaps like Bentley.

A very interesting marriage in the gardening world came off on the rocky coast near Dalkey. The wedding was quiet, but not the less worth noting. Taking place without witnesses, which was very irregular, of course, nothing probably would have been heard of it had not Mr. Burbidge in his rock rambling have discovered the contracting parties and their progeny. Some dozen of the children he ran down in the grounds of Sir Francis Brady; killed 'em by drying, and the mummified remains are now decently interred (?) in his *Hortus Siccus*. It appears, on evidence, that years ago *Cineraria maritima* escaped from the confinement of some garden and made herself (or himself) quite at home on the Dalkey rocks, fell in love with Mr. (or Miss) Ragweed, *Senecio Jacobea*, and so faithful have they been in wedlock that their offspring have arisen here, there, and everywhere in the locality. The resemblance to both father and mother is too striking to admit doubts as to their parentage.

After twenty years friend Hardy, of Dunardagh, is "knocked about." Death has taken the master, George Orr Wilson, Esq., and the auctioneer's hammer has dispersed the plants it has been his (Mr. Hardy's) labour of love to collect and grow. All credit to him that he should work as energetically to the last as he did from the first, for there are few plant auctions so well arranged and prepared for as was the Dunardagh sale. Taken all round, he is probably satisfied with the prices realised, although when he and the auctioneer mounted the rostrum—stage—in the Palm house he growled and looked real wicked as a superb specimen *Areca* was knocked down at less value than the teak tub containing it. So does a good man take the keenest interest in his care to the last. May the fates be propitious in resettling him as well as he deserves.

The People's Gardens in the Phoenix Park never looked, folk say, better or brighter than they have this season. That praise is emphatically endorsed, and can also be accorded to Mr. Kearney's work in Stephen's Green. One massive bed in the People's Gardens, composed of the silvery *Centaurea* with a fine dark *Heliotrope* interspersed, is particularly striking, and some huge clumps of *Tritomas*, standing out boldly against a background of evergreens, are simply grand. In our own somewhat limited field of labour a couple of sunny days have brightened up things considerably, and brought out a host of cheery blossoms to liven us up. Perennial Sunflowers, Cactus Dahlias, Golden Rod, Michaelmas Daisies, scarlet *Lobelia*, the last Rose of summer finely represented by Ulrich Brunner, La France, and red and white *Rugosas*, with "lashins" of Sweet Peas contribute the lion's share; whilst the Italian garden is at its best. In a warm corner *Eucomis punctata*, the Pine-apple Lily, has just thrown up a strong spike of sober looking blossoms from its crown of broad, handsome foliage. So much for the lighter side of gardening life in Ireland; there are, of course, more grievances one could give, but they need not detain, being, as they are, mostly Irish.—K., Dublin.

### A Famous Chilian Pine.

All those who have visited Dropmore Park, near Cliveden, Bucks, will hear with regret of the decay and death of the magnificent Chilian Pine, said to be the finest specimen in Europe, and which was presented to Lady Louisa Fortescue by George IV. in 1830, other trees of a similar kind being planted at the same time in Kew Gardens. The growth of the one at Dropmore proved wonderfully symmetrical, the branches, from the ground upward, being in every way perfect. Signs of decay in this famous "Monkey Puzzle" were observed at the beginning of the present year, and everything possible was done to save it, but without success. It is now quite lifeless. The roots are supposed to have been attacked by some malady the nature of which has not yet been determined.

## A Biography of Dr. Lindley.

John Lindley was born February 5, 1799, at Catton, near Norwich, which may now be styled the City of Botanists, for there were born three of England's greatest botanists—Sir James Edward Smith, Sir William Jackson Hooker, and Dr. John Lindley. His father was a nurseryman, but being unsuccessful in business, he subsequently undertook the direction of the Bristol Nurseries of Miller and Sweet, at that time one of the most extensive and prosperous establishments in the kingdom. He was the author of a very useful work, which was edited by his son, entitled "A Guide to the Orchard and Kitchen Garden," but it appeared at a time when the present taste for garden literature was as yet undeveloped, and when what is now called gardening was confined more to the establishments of the higher classes, who were themselves not gardeners, and consequently that excellent work never met with the encouragement it merited, and never reached a second edition. Trained as young Lindley necessarily was among plants and flowers, and being surrounded by so many botanical associations and associates, it is not to be wondered at that an intellect like his should soar above and beyond the ordinary ideas of a nurseryman, and see something in the objects with which he was surrounded of greater interest than that which was connected with their commercial value. We find, therefore, that instead of being a nurseryman he was bent on becoming a botanist, for so early as 1819 he published a translation of Richard's "Analyse des Fruits;" and in his twenty-first year he produced his "Rosarum Monographia," the preparation of which must have occupied him a long time previously, for the excellent plates are all from his own drawings, and the study of the subject must necessarily have engaged his attention at a period when he was yet a mere youth.

In the following year Mr. Lindley published "Digitalium Monographia," and about this time he became garden clerk at the Chiswick Garden of the (Royal) Horticultural Society, which had then been newly formed; and in this capacity he remained till the retirement of Mr. Sabine in 1830, when Mr. Bentham was chosen secretary and Mr. Lindley was appointed the assistant secretary. In this capacity he remained till his retirement in 1858; and, as a recognition of his long services to the Society he was chosen secretary—an honorary appointment he retained till 1863. About the time he became connected with the Horticultural Society, he was engaged by Mr. Loudon in the compilation of the "Encyclopædia of Plants," which occupied him for a period of seven years, and which was completed in 1829.

During the time he acted as assistant secretary to the (Royal) Horticultural Society, he held several other appointments. In 1826 he succeeded Mr. Bellenden Ker as editor of the "Botanical Register," established by Sydenham Edwards in 1815; and the botanical attainments he exhibited in the management of this and the execution of his other works recommended him to the botanical chair of University College, London, where, in the end of April, 1829, he delivered his introductory lecture as Professor

of Botany in that institution. This appointment he held for twenty-nine years; and it has been remarked by one of his old pupils, "I can truly say, as a lecturer he was one of the best teachers I ever heard. Free and conversational in his manner, his matter was excellent and methodically arranged. I entered his class with little knowledge of, and less liking for, botany, and left it, having taken his gold medal at University College, having amongst my competitors Dr. W. B. Carpenter, Dr. Lankester, Dr. Jenner, &c., and I maintained the superiority of his teaching by taking the silver botanical medal of the Apothecaries' Company open to the competition of all the students in England."

In his introductory lecture he announced his intention of teaching the natural system of botany, at that time unpopular among those who had been educated in the Linnæan school: to this he rigidly adhered. We question, however, whether so much of the credit usually attributed to Dr. Lindley as the fosterer of the natural system in this country is not unduly rendered. He encouraged the study of it in preference to that

of the Linnæan, and in all his works on the subject he adhered to that system. Still it cannot be forgotten that, not content with the natural systems which Jussieu and De Candolle originated, he was always propounding some theory of his own, which was never fixed, but which at uncertain intervals was doomed to be supplanted by another idea that seemed to find greater favour in the mind of the author. Students who were willing to adopt the natural system were thus, by Dr. Lindley's teaching, kept in a state of constant uncertainty. In his "Synopsis of the British Flora," published in 1829, he there adopts the arrangement of De Candolle, a system which has received universal acceptance from every botanist in this country and America; but in 1830 appeared his first elementary work on the natural system, entitled "An Introduction to the Natural System of

1799—DR. LINDLEY AT 50—1865.

Botany." Instead of following the systems of Jussieu and De Candolle, he adopted that of the latter, ignoring the apetalous classes of both, and throwing them in with the polypetalous class. This, as a consequence destroyed any ideas of sequence, or even of arrangement, that may have been formed by the student who had just mastered either of the other systems, and confused those of others who were but on the threshold of the science.

In 1833 Dr. Lindley published his "Nixus Plantarum," in which he restored the apetalous group, which three years previously he abolished, and ignored altogether the hypogynous and perigynous structures, which form such distinct characters in the other systems; retaining only the epigynous, which he made to represent a subordinate section, and adopting the character of the albumen for the primary divisions. In this case the affinities and sequence of the orders were again entirely disturbed. Three years later appeared the second edition of "A Natural System of Botany," in which the arrangement set forth in the "Nixus" was generally adhered to, but differed in some of the details, and this form he introduced in the subject "Botany," published by the Society for the Diffusion of Useful Knowledge in 1838, and which was intended as a book of instruction for the masses; but there is not even a reference in it to the system of De Candolle, which at the time was being taught by Hooker in Glasgow,

Graham in Edinburgh, and Henslow in Cambridge, and which is that now generally accepted and taught in every institution of the country.

In 1845 appeared "The Vegetable Kingdom," with a wholly new arrangement, differing entirely from all the others he had previously been labouring to introduce. In this he restored the great hypogynous, perigynous, epigynous, and deelinous divisions of Jussieu, and suppresses the apetalous, which he distributes among the other divisions. This is, undoubtedly, by far the best scheme he has ever proposed, and had he introduced such a system in 1833, instead of that set forth in the "Nixus," he might have lived to see it adopted in botanical education as a formidable rival to that of De Candolle. But this last and certainly his best effort, was the result of a gradual building up of material prepared by others. It was first of all a recurrence to the Jussieuan and Candollean systems, with the adoption of such views as had previously been enunciated by Bartling, Endlicher, Martius, Brongniart, and others, aided by the labours of our own countrymen, the Hookers, Bentham, Griffith, Gardner, Miers, Wright, and more, but it came too late for adoption.

It is not, however, with the view of drawing attention to what may be supposed Dr. Lindley's uncertain ideas with regard to classification that we have directed attention to these matters, but rather to show that an opinion we have often heard expressed, to the effect that it is to him we are indebted in this country for the adoption of the natural system as it is now taught, is not a correct one; and that if students in botany had relied for guidance on the works of Dr. Lindley alone, they must have experienced that feeling of insecurity that one has when in a strange country he places himself under a guide who hesitates at every deviation of the beaten track.

In 1832, Mr. Lindley received from the University of Munich the honorary degree of "Doctor of Philosophy," and henceforth was known as Dr. Lindley. In 1834 he published "Ladies' Botany," a work in two volumes, and written in a familiar and popular style in the form of letters; but whether the style of the letters did not suit their taste, or the subject their capacity, or whether it was that what is suitable for gentlemen is not equally so for ladies, the work proved a failure, and has long since fallen into obscurity.

He was a voluminous writer, and besides those of his works to which we have already referred, and numerous others of smaller character, he was the author of an "Introduction to Botany," which passed through four editions; "The Genera and Species of Orchidaceous Plants;" "Sertum Orchidaceum;" "School Botany;" "Elements of Botany," &c.; and, in conjunction with Mr. Hutton, "The Fossil Flora of Great Britain." His greatest and best works are "The Vegetable Kingdom," already referred to, and "The Theory of Horticulture," the first edition of which appeared in 1840, and the second under the title of "The Theory and Practice of Horticulture," in 1855. In 1841 he united in establishing the "Gardeners' Chronicle," of which he remained the editor till the summer of 1865, when he was succeeded in that office by Dr. M. T. Masters.

Dr. Lindley was a Fellow of the Royal and Linnæan Societies, and a member of most of the learned societies of Europe. He was awarded the gold medal of the Royal Society, and in 1863 his friends presented him with a piece of plate in the form of a candelabrum as a testimony of their regard.

Dr. Lindley was not what might be termed a great botanist. He raised himself to a degree of eminence, not so much as a botanist as a journalist, and by his connection with the (Royal) Horticultural Society. With the exception of his works on the Orchidaceæ, and the "Vegetable Kingdom," he did not contribute much to the store of botanical knowledge; and when we compare what he did for the extension and encouragement of the science with the labours of Sir William Hooker, or his contributions to it with those of Dr. Bentham and Dr. Hooker, we are not inclined to concede to him so high a position in the rank of botanists. What he might have attained if he had devoted that time to botany which he gave to journalism, can, of course, only be left to conjecture.

He was a man of an extraordinary energy and activity of mind frequently amounting to impetuosity; yet he had not the philosophic mind of Darwin, or Mohl, or De Candolle, and many others. His name does not rank with those of Ray or Robert Brown. But although he came short of all those qualities he had great powers of generalisation and adaptation, and he could so combine and apply the views of others as to render them practical and popular, as has been so well exemplified in "The Theory and Practice of Horticulture" and "The Vegetable Kingdom."

It was, therefore, rather as a teacher that he achieved his greatest success. His classes at one time were well attended; and it spoke much in his favour that his students frequently numbered as many as two hundred, the greater number of whom were purely voluntary, and not compelled by any college curriculum to attend on the course. Still, as a teacher he never attained the position of Sir William Hooker, Professor Henslow, or Edward Forbes, and he will be remembered more as a man of action than of deep scientific thought.

## Crocus speciosus, M. Bieb.

It is surprising that the worth of the autumn-flowering Crocus is as yet hardly recognised, and that so few gardens possess even one species of this lovely and valuable flower. The Colchicum, a less attractive flower, is better represented, and, unfortunately, the name of "autumn Crocus" has been so commonly applied to it that when one mentions the "autumn Crocus" most people assume that it is the Meadow Saffron to which one refers. I should be one of the last to depreciate the value of the Colchicum, which has a place of its own in the garden and ought to be indispensable, but the true Crocus is so delightful in autumn that it ought to be cultivated as well. To tell of the numerous species which bloom in autumn or early winter would take up a considerable space, so that I purpose only mentioning now one of the best, if not the best, of these autumnal Croci, *C. speciosus*, the "showy" or "blue" autumn Crocus. It is one of the finest of all Crocuses, and one only longs for its greater appreciation, an appreciation which might even lead to its improvement. *C. speciosus* is pretty widely distributed in its range of habitat, occurring, as Mr. George Maw tells us, from North Persia, through the eastern parts of Asia Minor, the Caucasus, and the Crimea, to the province of Podolia, in southern Russia. Maw doubts the record of its occurrence in Transylvania, but since his monograph appeared its known habitats have been extended by the discovery in Afghanistan of the fine variety, *C. s. Aitchisoni*, which has rapidly become popular. He classes it with the nudiflori, or species without a basal spathe, and with the annulati, i.e., the species with a basal corm tunic composed of coriaceous annuli.

A noteworthy point about this species is that it is one of the few Crocuses which produces its bud growths as bulblets or cormlets round the base of the old corm, where they remain without producing foliage for the first year. Another is that it has the longest petals or segments of any of the species known to Mr. Maw, who gives the comparison with *C. parviflorus*, as between half an inch in the latter and an inch and a half for *C. speciosus*. There can be no question regarding the beauty of this fine Crocus, which flowers in September and October in ordinary seasons (this year I had no blooms until the beginning of October), and no one can fail to appreciate its large blossoms of pale lilac or blue, so beautifully marked with deeper blue or, rather, purple feathering all over the flower. A mass of this Crocus presents a charming spectacle when the autumnal sun causes the blooms to open widely to its rays. When quickly grown, they are most pleasing, as they then present an unbroken mass of colouring, the leaves not appearing until after the flowers have vanished. The leaves are at times as much as 15 in in length at maturity, so that those who plant this fine Crocus will require to take their habit into consideration.

The variety *Aitchisoni*, from Afghanistan is a fine one, though I think that its lighter colour is rather a defect. On the other hand, it is a little later, a recommendation to some, and it is also larger, and it seems to me to open out more flatly to the sun. It is as prolific as the type, and soon increases rapidly. Any one who admires the noble Crocus *speciosus* would like to have a little further variety. This is not easily secured, as it appears to be a species which varies little in its native habitats, there being no well-marked varieties except *C. s. Aitchisoni*, so far as I am aware. In consequence, our best chance of obtaining some variety would appear to be by means of raising seedlings. Unfortunately, it is a species which seeds badly with me, the frequency with which we have wet autumns preventing its fertilisation and formation of its seeds. I have only saved seeds some twice out of fifteen or sixteen years, but from some purchased seeds I have one variety with much larger blooms than ordinary. I hope that this will thrive with me. May I ask those who cultivate this fine Crocus to endeavour to raise seedlings? With regard to the cultivation of *C. speciosus* one need say little. It can be grown as easily as any common spring Crocus, and is a charming occupant of the border, rock-garden, or of the lawn or wilder grass plot or meadow. It is an exquisite species, well worth growing by all who are admirers of the hardy bulbous or cormous flowers.—S. ARNOTT.

### Another Yellow Calla.

This interesting new plant was recently awarded a medal by the Massachusetts Horticultural Society, U.S.A., the raiser being Jos. Tailby, Wellesley, Mass. The plant is the result of a cross between *Richardia* (*Calla*) *Elliotiana* and *R. albomaculata*. Out of the batch of resultant seedlings one plant showed special merit, and was increased both by offsets and by seedlings, and it has been proved that the type is well fixed, for the variety comes true from seed. The colour is of a beautiful primrose yellow, with flowers equal in size to those of *R. Elliotiana* borne on stout stems, the leaves being beautifully spotted with white.

### Some Pillar Roses.

There are several things that already remind us of the approaching autumn and winter. The days are already much shorter, the leaves are beginning to fall, and the ingathering of the fruits of the earth are amongst these reminders. The interest of many will soon be centred on preparing for and planting of Roses. There are now so many sections of Roses that may be used in so many different ways that it is not always an easy matter, especially for a beginner, to decide what will be the most satisfactory to plant.

In these notes, however, we only intend to deal with that section of Roses that are very popular, and deservedly so, at the present time, pillar Roses. The place of honour must be given to *Crimson Rambler* (1893), even if it is sometimes decried. There is no Rose of recent introduction that has had such a distribution, or become so popular as this. Not only do we find it in the gardens of the rich, but also in cottage gardens, where it is much prized. It is a most accommodating Rose, as it may be used in so many different ways with equally good effect; but for arches and pillars it is an ideal Rose. When properly pruned, its large clusters of flowers are produced all round the pillars, from near the ground line to the top. The flowering period will extend over several weeks; indeed, a few may be found quite late into the autumn. To obtain the best results, however, it must have good treatment.

*Alister Stella Gray* is not such a strong grower as the above, but it makes a beautiful pillar Rose. The flowers are produced in large clusters—pale yellow with orange centre, almost white when fully expanded. It is a very chaste Rose, and should be included where pillar Roses are prized. For autumn blooming it is one of the best, and has been particularly good this autumn.

In *Aimée Vibert* we have one of our oldest *Noisette* Roses. Although it is often used for arches and pillars, it does not lend itself so readily as do many others, being, perhaps, more suitable for rambling over a bank, or pegging down and forming a large bush. *Gloire de Dijon* is too well known to need any description. No doubt this is the most familiar of all Roses, its hardiness and free flowering character making it suitable for all to grow. Grown more on walls than any other Rose, perhaps, but it also makes a good pillar specimen.

*Reine Marie Henriette*, often called a Red *Gloire*, is not so well known. It is a free grower, and gives some beautiful blooms. They are globular, rather loose, and sweetly scented. If it flowered as freely as the White *Gloire*, its usefulness would be greatly enhanced. I find it very subject to attacks of mildew. Another good red pillar Rose is to be found in *Reine Olga de Wurtemberg*. A very strong grower, with large leaves and semi-double flowers, but it does not appear to be a very free bloomer. The *Waltham Climbers* are excellent, and these I will have something to say about in your next issue.—J. S. U.

### Roses at Coventry.

When on a visit (early in September) to the "City of Spires," an opportunity was afforded to make a visit to the rosarium of Messrs. Perkins and Sons. This firm has a newly acquired site, situate about a mile and a half from the home establishment, in close proximity to the railway station. To the florist especially the names of Perkins and Coventry are synonymous, as the mention of one is a reminder of the other. A pleasant drive through devious lanes landed us at the venue in question, amidst purely pastoral scenery.

The Rose nursery consists of about twelve acres of old grass land, fully exposed, with a gentle trend towards the north-west, and as yet is devoid of sheltering hedges to protect the Roses from the fierce winterly winds. Such necessary screens, however, are in contemplation to be formed, principally of Beech. No material harm has been experienced. The staple soil is admirably adapted for Rose culture, as evidenced by the wonderfully vigorous growth of every plant, whether Hybrid Perpetual, Tea, or Hybrid Tea. The soil is composed of a strong, unctuous, reddish loam, of about 3ft in depth, superimposing a deep stratum of clay, rendered friable by exposure to frost. My guide, the elder member of the firm, and an ardent rosarian, I found actively engaged in superintending that all-important employment, "budding," prior to departing for a well-earned holiday.

The principal stock used for dwarf-trained Roses is the seedling Briar, also Briars from cuttings, and comparatively little difference was perceptible in their strength, or of the quality of the Roses grown upon them. The *Manetti* stock is

also largely employed, likewise the *Griffere*, of which Mr. Perkins has a high estimation for certain varieties of Roses, rendering them almost mildew proof. To the uninitiated, the process of budding on the dwarf stocks in question is interesting and puzzling, the bud being inserted close to the ground, below the tangled masses of Briar shoots of two seasons' growth. The great desiderata is to keep newly inserted buds from making growth before the spring season, when the masses of Briar shoots are entirely cut away, so that the dormant buds of the Roses derive the whole benefit of sap from the rootstock. The autumn Roses were indeed a glorious sight. The Hybrid Teas especially presented a grand feature, whilst also several of the Hybrid Perpetuals were remarkable for fine form and intensity of colour.

Standard Roses are largely grown. It should have been mentioned regarding the *Griffere* stock that Mr. Perkins considers it to be eminently suitable for strong climbing Roses. The new hybrid *Wichuriana* Roses were noted doing remarkably well, and two high stumps of old Oak trees in the centre of the garden were being furnished with young plants of them. These are essentially creeping or trailing Roses. To enumerate even the cream of the varieties would almost be an invidious task, and it is needless to say that the newest varieties were in evidence. Mention may be made of such as *Horace Vernet*, of a fine velvety purple red, shaded with dark crimson, large, full and of fine form; also *Captain Hayward*, *Paul Neyron*, *Merveille de Lyon*, and *Exposition de Brie*, a fine autumn bloomer, whilst *Caroline Testout* is one of the finest autumn Roses in existence. The two old nurseries contain Dahlias, Phloxes, Gladioli, and a host of herbaceous perennials.—G.

### Ordering Roses.

Roses should be ordered as soon as possible after the Rose catalogues are issued in October, since this will ensure the arrival of the plants as early in November as they can with safety be removed from the nurseries, and the probability of obtaining the best plants, because these are usually sold first.

## Gadding and Gathering.

"HERE AWA', THERE AWA'."

### New Cactus Dahlias.

A considerable number of novelties amongst Cactus Dahlias were certificated at the meetings that have been held in London during the season which is now practically closed. Those mentioned beneath are all new, though all have not received certificates. That fact, however, is not always a guide to the real merits of a flower for the garden, and some of the non-certificated flowers are better lasting, and have charms which are quite sufficient to entitle them to special notice. It is presumed that the undermentioned will be in commerce during and after next spring.

**H. J. JONES.**—A handsome flower, with deep primrose centre, the petals surrounding the middle being flat, but those at the base of the blooms are beautifully fluted and very lengthy, radiating attractively. It is one of the most effective new varieties of the past season.

**RINGDOVE.**—Though this variety was not certificated, it is yet one of the prettiest novelties seen at the London shows. The petals are rather too broad, reminding one of the older type of Cactus Dahlia, and the colour may not suit everyone. It is orange-red, with the tips of the petals a light, faded, silvery-lilac—a novel colour.

**PRINCE OF ORANGE** is one of the best among newcomers. The flower is of the popular incurved form, with finely fluted and narrow petals. The centre is of a deep glowing golden shade, passing off to a salmon red tint towards the basal half of the flower.

**F. A. WELLESLEY** is undoubtedly one of the best half-dozen of last season's novelties. The large blooms are well held up on dark-skinned wiry stems. The incurving, fluted florets are deep, bright cherry-red or crimson, and there is plenty of material in each flower, yet it is not clumsy. It is one to be especially noted.

**MRS. T. CHERRY** has a capital, bud-like, and firm centre, but is of very moderate size. The colour is bright lilac-red. It is distinctive, though not very effective for garden decoration. In vases and bowls the colour would be novel.

**REDCAP** is a splendid little flower, quite a gem for decorative uses. The blossoms are small, but "smartly" built, with firm florets, nicely fluted and incurving at the tips. It is a pretty, rounded flower, coloured bright crimson, with a dash of scarlet.

**VESTIVUS.**—From what was seen of this variety of Fancy Cactus Dahlia at the recent exhibitions, it seems to be a flower to last well. It has a splendid conical centre, and the petals incurve. They are somewhat broadened at the base. The ground-colour is deep yellow with a shade of bronze, and splashed with bright crimson.

**EVA.**—This is the purest white variety we have, and is a novelty of this year. The size is only moderate, and the centres of the flowers and the quantity of petals composing them were inclined to be weak and spare from what I have seen of it. The florets or petals curve centrewards. No doubt it may be seen in better condition another year.

**WINSOME** would seem to be poor as a staying flower, for at the exhibitions it soon faded. This is a great drawback in any Cactus Dahlia, and raisers should select varieties with stamina. The irregular petals are ivory white, and considerably broadened.

**ALBION** came forward this year for the first time, and was thought by some connoisseurs to be the best novelty of the season. The blooms remain fresh for a couple of days, and are well built and nicely filled. The long radiating petals are white, or ivory white, and strong. It is a really good Cactus Dahlia.

**ENCHANTMENT** has a greenish-primrose centre, and becomes purplish mauve towards the outer parts of the flower. It is a pretty and attractive flower, of fair size, the petals being nicely fluted.

**IDA**, as a flower, is of a deeper yellow than Mrs. E. Mawley, and probably on that account loses in delicacy. The flower furnishes an uncommon type of Cactus Dahlia, for the florets are arranged in swirlpool order, each inclined in rotary fashion. The petals are narrowly fluted and strong. It is decidedly a good flower.

**MARY FARNSWORTH** is distinctly a bicolor Cactus, the centre being soft canary yellow, while the tips of the lower petals are white. The blooms, however, are slack and poor.

**THE KING** furnishes a smart bloom of moderate size, but of good substance and firm. The florets are narrow, fluted, and incurving—qualities which one always looks for in a present-day Cactus flower—and are a deep ruby-crimson. An attractive and showy novelty.

**CLARENCE WEBB** is decidedly a good variety, of a cheery colour combination, that is, salmon centre and reddish orange petals. The peculiarly irregular disposition of the fluted and marching petals gives much charm to the flowers.

Amongst other varieties of high excellence, some of which are new and others well-known, may be mentioned the following:—Imperator, Mrs. E. Mawley, Mrs. H. J. Jones, Gabriel, Floradora, Rosine, P. W. Tulloch, Mrs. Carter Page, Mrs. J. J. Crowe, Mayor Tuppeney, J. W. Wilkinson, Lord Roberts, R. Dean, and Vesta.

#### Myatt's Fields, Camberwell.

Myatt's Fields is the name of a small public park and playing ground in Camberwell, one of the most densely populated districts in south-east London. The park is situated on part of the highest ground in the district, and is comparatively open and breezy. Villas are seen through the screen belt of trees and shrubs on every side, and the interior features of the park itself are interestingly disposed. Poplars, Planes, and Limes are the prevailing trees here, as in many other parts of London; and a diversified selection of the arborescent tribe are included, among which are berried Cratæguses, Acacias, golden and green leaved Catalpas, various species of Berberis, Genistas, Ailantus, and Rhus. Some robust Fig trees were noticed in companionship with less pretentious members in the shrubbery, and showed off most advantageously in such position. The Fig has bold and handsome foliage. Yuccas as ornamental specimens on the grass verges and by the forefront of the shrubberies, also deserve remark.

Hardy herbaceous perennials and half-hardy annuals are planted in front of all the shrubberies, to their improvement in colour, richness, and brightness. Mr. F. W. Wright is the officer in charge, and entered on his superintendence during the present year. Mr. Wright was previously head of the Victoria Gardens along the Thames Embankment, and was for a good many years "second in command" at the large Victoria Park, in the East End.

A pretty feature of Myatt's Fields is the transverse Lime avenue about the centre of the grounds, which affords a shady recess on a sunny summer day. There is a considerable amount of grass land for the use of those who practise the popular games, and all the park is exceedingly smart and well kept. The walks, so finely sanded and smooth, were an especial pleasure to me, a stranger there. A tennis lawn is provided, and the presence of a nursery within the park denotes that shrubs and bedding plants for the annual requirements are raised there. The formal flower beds are mainly situated around the large band-stand, and presented a very bright display in effective arrangements at the time of my visit in September.

#### Apples that Colour Well.

The good colouring qualities of Apple fruits is a point of prominent consideration with certain growers, market-

men in particular, and the following varieties are generally found to be characteristically brightly or well coloured:—Worcester Pearmain, Duchess of Oldenburg, Duchess's Favourite, Lady Sudeley, Devonshire Querrenden, Hoary Morning, Golden Noble, American Mother, Red Astrachan, Belle de Boskoop, Williams' Favourite, Winter Pearmain, Cellini Pippin, Tom Putt, Golden Spire, Irish Peach, Ben's Red, Red Streak, Bietigheimer Red, Okera, Ribston Pippin, Cox's Orange Pippin, King of the Pippins, Paroquet, Belle de Pontoise, Gascoigne's Scarlet, Emperor Alexander, Fearn's Pippin, James Grieve, Yellow Ingestrie, and Wealthy.—WANDERING WILLIE.

#### CYCAS REVOLUTA AT HOME.

The tall Cycas plants portrayed on this page are of interest to those of us who are accustomed to see only pot-grown specimens in the stoves of home gardens. They grew upon the site of what had once been a cemetery adjacent to the town of Paramaribo (or Surinam), in Dutch Guayana, S. America. The tallest specimen was 9ft 3in high, the second tallest was 8½ft, and the third 8ft. They were estimated to be over 100 years old. Infinitely more female than male plants are known to exist. Regarding the genus, the following notes occur in Lindley and Moore's "Treasury of Botany," part 1, page 368:—"A remarkable genus giving its name to the order Cycadaceæ. It consists of trees of no great height, with cylindrical usually unbranched stems, terminated at the top by a crown of handsome deeply cut pinnate leaves of thick texture. The male flowers grow in cones, consisting of scales bearing anthers on their under surface. The female plants bear in the centre of the crown of leaves surmounting the stem a tuft of woolly pinnately cleft leaves, in the notches of whose margins the naked or uncovered ovules are placed. The species are natives of the tropical regions of Australia, Polynesia, and Asia. *C. circinalis* furnishes in Malabar a sort of sago, which is prepared from the seeds, which are dried and powdered; medicinal properties are attributed to the seeds, but these are of little importance. The plant is said to be singularly tenacious of life. The pith in the interior of the stem of *C. revoluta* abounds in starch, which is highly esteemed in Japan. A clear gum exudes from the trunks of these trees, which is said to be employed by the natives of India in promoting speedy suppuration. These elegant species are great ornaments in our plant houses. A fine group of them and of the allied genera may be seen at one end of the large Palm house at Kew. They are popularly but erroneously called Sago Palms, as they furnish none of the sago of commerce."

Cycas revoluta at Home

# NOTES & NOTICES

## Sheffield Chrysanthemum Show.

The annual show of the Sheffield Chrysanthemum Society will be held in the Cutlers' Hall on November 14 and 15.

## Surrey County Council.

At the Egham Technical Institute, a course of twenty demonstration lessons on the principles of horticulture will be given by Wilfred Mark Webb, F.L.S., on Tuesday evenings from 6.40 to 8.40 (commenced September 30, 1902). Baron Schröder has been so good as to offer two prizes (25s. and 15s.) to be competed for by the students.

## Bolton Horticultural Society.

The opening monthly meeting of the M.I.C. in connection with the Bolton Horticultural and Chrysanthemum Society was held on Tuesday, October 7, in the Spinners' Hall, when a paper on "The Chrysanthemum for Exhibition" was read. The chair was occupied by Mr. R. Smith. The paper was one of the best and most practicable given during the existence of the society, and in a most instructive manner gave full details necessary for the successful cultivation of the Chrysanthemum.

## German School Gardens.

For nearly a century past Germany has been alive to the supreme importance of training the children of agricultural districts in the intelligent cultivation of the land. A large proportion of elementary village schools are provided with garden ground where the elder children are trained in the grafting and management of fruit trees, of vegetables, and of flowers as are best suited to the conditions of the particular district. Even town schools, it would seem, are not left out of the general scheme, and have their allotted garden plots.

## Pot-Grown Bananas.

The home-grown Bananas are greatly superior in flavour to those imported from abroad. It is not generally known that very satisfactory returns can be obtained from small pot-grown Banana plants, and at South Norwood we have seen sturdy plants bearing huge bunches in a very narrow stove-corridor, the plant, however, being in a border. At Syon House, the seat of the Duke of Northumberland, Mr. George Wythes produces heavy annual yields from a dozen plants in large pots formed of the ordinary material, and the house in which the plants are cultivated is quite a small house. The photograph of a plant shown on another page this week, bears out these remarks about pot-grown Bananas. This specimen was photographed in the gardens of Captain Belfield, at Frenchay, near Bristol.

## An Extensive Apple Orchard.

A company composed of representative horticulturists in Iowa and Missouri has been organised, with a capital stock of 1,000,000dols, for the planting of what it is claimed is to be the largest orchard in the world. This orchard is to cover 5,000 acres of ground planted with fifty trees to the acre. About 1,000 acres will be planted next spring. While the main object of the company is that of raising Apples, many Peach and other trees devoted to small fruit will be planted during the first years, in order to produce an early dividend upon the investment. It is estimated that each of the 250,000 trees to be planted will produce five bushels of Apples, thus making a total yield of 1,250,000 bushels, equivalent to about 500,000 barrels. It is expected that the bulk of this crop will be exported to Europe. During the fiscal year of 1901 the export of Apples from the United States was 840,605 bushels, of which 794,660 were sent to the United Kingdom. As showing some of the methods to be adopted, a cold storage plant will be built in St. Louis as soon as this orchard has come into bearing. This will be the main shipping point, and it is intended that the storage plant shall have a capacity for 150,000 bushels. The St. Louis and San Francisco Railroad has agreed to construct a branch of about three and a half miles through the property.

## Appointments.

Mr. Richard Wilson, gardener to Sir A. Edmonstone, Bart., Duntreath Castle, Blane, Stirlingshire, has been appointed gardener to Sir John Watson, Bart., Earnock, Lanarkshire, in room of Mr. James Moir. \* \* Mr. J. Wright, late of Hopton Hall Gardens, Wirksworth, as head gardener at The Holts, Newent, Gloucestershire. \* \* Mr. David Quinn, formerly foreman in the gardens at Obelisk Park, Blackrock, Co. Dublin, has been appointed head gardener to J. P. Goodbody, Esq., Inchmure, Clara, King's County.

## The King as Tree Planter.

His Majesty the King planted a purple-leaved Sycamore (*Acer pseudo-Platanus atro-purpureum*) in Quality Street, North Berwick, on October 10, at the request of the Town Council, in commemoration of his visit there. The tree was a well-grown specimen about 12ft high, supplied by Mr. John Downie, Edinburgh. The spade used by the King had an oak shaft and a silver blade, bearing the North Berwick coat-of-arms, with the following inscription: "Spade used by His Majesty King Edward VII. in planting a tree at North Berwick on October 10, 1902."

## Royal Horticultural Society.

The next fruit and flower show of the Royal Horticultural Society will be held on Tuesday, October 21, in the Drill Hall, Buckingham Gate, Westminster, at 1-4 p.m. A lecture on "Hardy Summer and Autumn Flowering Bulbs" will be given by Mr. P. Rudolph Barr, F.R.H.S. At this meeting the president of the society will confer the Victoria Medal of Honour on Mr. John T. Bennett-Poë, M.A., Mr. Henry Cannell, and Mr. George Massee, F.L.S., at three o'clock. \* \* At a general meeting of the Royal Horticultural Society, held on Tuesday, October 7, forty new Fellows were elected, making a total of 975 elected since the beginning of the present year.

## Oxfordshire County Council.

Some time ago we received the report of the instructor in horticulture (Mr. S. Heaton) to the Oxfordshire County Council; this report ending with June 30, 1902. The County Council trial allotments are all reported on statistically, showing the number of points accorded to each, and Mr. Heaton goes on to explain the general work of the year and what demonstrations were given. For the year sixty-one demonstrations were given, and attended by 706 persons. Many of his pupils sat for the Royal Horticultural Society's examination and proved successful. The following subjects were practically demonstrated, namely, trenching, digging, manuring, sowing, planting, potting, pruning, training, disbudding, stopping, staking, tying, propagating by grafting, layering, and cuttings, and fruit tree spraying, &c. One hundred and fifty-six lectures were given during the year, attended by 2,699 persons.

## Lilium auratum.

The figure of *Lilium auratum*, illustrated on another page, is from a photograph sent by Mr. John R. Denner, gardener at Shute Leigh, Wellington, Somerset, who writes as follows:—"The photo of *Lilium auratum* is that of a plant growing in a bog-bed, between Azaleas and Rhododendrons, as may be seen, and I think it a very unusual specimen. It may interest your readers if I give a few details of its planting and development. It was planted in this bed about four years ago; it was not a strong bulb selected for the purpose of planting out, but an exhausted bulb, turned out of a pot after blooming; and it has gradually increased in size and vigour ever since. Last year it threw one spike containing fifty-two grand blooms. [A case of fasciation.—Ed.] This year it has two spikes, as may be seen, and one of them had about forty, and the other more than 140 perfect blooms. There are other bulbs of the same variety planted in the same bed at different times, and they are all vigorous in growth, carrying twenty to forty blooms; one had sixty, but this did not perfect all its blooms. Of course it is well known that the *Lilium auratum* has proved to be hardy, and we see it at its best when grown in the open. I would like to ask if it was unusual to get so many blooms on one spike?" [It is not uncommon. At Leven-grove Park, Dumbarton, N.B., an habitually fasciated specimen bore 300 flowers, in one long raceme, this year. See page 265 of the present volume.—Ed.]

**Apples as Advertisers.**

The Canadian Office in Victoria Street is just now redolent of large and luscious Apples grown in Manitoba. These Apples are the direct result of a challenge to the effect that Manitoba was too cold a country to grow such fruit to perfection, and have been sent over here to be distributed among the different Canadian agencies scattered about the kingdom to act as advertisers of the gentle mildness of the climate.

**Scottish Horticultural Association.**

Through an error in our reporter's notes on page 344, we regret that the credit of the very meritorious collection of Sweet Peas shown at the latest meeting of the Association was not given to Mr. Thomas Duncan, Foggo Schoolhouse, Berwickshire, who was the grower and exhibitor. As already stated, they were wonderfully fine for the late period of the season, being rich and fresh in colour, perfect in bloom, with long flower stems.

**Rose Growing in London.**

A Liverpool paper says the Rose growing industry in the suburbs of London is reported as becoming less remunerative year after year. An instance is given in which one of the biggest growers at Lower Edmonton sent a large number of boxes to Covent Garden Market. Each box contained about 300 cultivated Roses, and although 5s. a box has been considered a very low price, he was unable to realise even 1s. per box. The Roses had to be taken home, and some were sent round to the hospitals.

**Fruiterers at the Mansion House.**

The Lord Mayor of London on Tuesday evening presided at the annual banquet of the Fruiterers' Company, and the company included the Lady Mayoress, Mr. J. Lea-Smith, the Master of the Fruiterers' Company, and Mrs. Lea-Smith; Mr. W. O. Clough, Chairman of the General Purposes Committee, and Mrs. Clough; Sir Henry and Lady Knight; Sir T. H. Elliott, Secretary to the Board of Agriculture, and Lady Elliott; Sir John and Lady Bell; Sir E. Clarke, Secretary to the Royal Agricultural Society, and Lady Clarke, and a large number of ladies and gentlemen connected with the City and the Fruiterers' Company. The offering of fruit which Mr. J. Lea-Smith then made on behalf of the Company of which he is Master included a magnificent collection of English-grown Pears, Apples, Grapes, Melons, and other fruits, which were arranged with great taste and effect in the drawing-room. It was urged that home produce might supersede much of the foreign fruit and vegetables which now come into this country, and Mr. J. Lea-Smith, in reply, explained that the Fruiterers' Company, although a comparatively poor one, had endeavoured to stimulate in various ways the efforts of home growers.

**Emigrants' Information.**

The October circulars of the Emigrants' Information Office and the annual editions of the penny handbooks show the present prospects of emigration. The notice boards are now exhibited, and the circulars may be obtained free of charge, at more than 900 public libraries, Urban District Councils, and Institutions throughout the country, or from 31, Broadway, Westminster, S.W. In Canada it is too late for emigrants to go there this year. In New South Wales, the country districts are suffering most from the severe drought, and in some parts it is impossible to obtain employment owing to want of water, and of feed for stock. In Victoria there is no general demand for more labour, and many men are out of work. No large public works are being proposed by Government which might provide employment. The drought has long pressed heavily on large portions of the State, and seriously affects pastoral, agricultural, and mining industries, but useful rains have lately fallen. There are excellent openings, as a rule, in this and the other Australian colonies, for farmers, dairy farmers, and fruit growers, if they have a little capital, and some experience of the country. In Western Australia there is a good demand for agricultural labourers in many districts. In Tasmania there is a moderate demand for skilled farm hands and female servants. In New Zealand there is a good opening for farmers with capital, farm labourers, miners, and female servants. In Cape Colony there is no demand for general or farm labourers, who are mainly coloured men.

Permits are required by those going to the Transvaal and the Orange River Colony, but not for Cape Colony. These will not be valid unless endorsed by the representatives of those Colonies at the port of disembarkation.

**Hastings and St. Leonards Horticultural Society.**

Mr. James Stredwick, the Cactus Dahlia specialist, will give a lantern lecture to the above society on October 23, his subject being "The Cactus Dahlia."

**For the Children.**

Messrs. Treherne and Co., Limited, publishers, 3, Agar Street, Charing Cross, W.C., are offering a prize of £5 for the best 300 word essay on "The Cat," written by a boy or girl under the age of fifteen.

**American Plant Breeding Conference.**

The International Conference on Plant Breeding and Hybridisation was held, by the kind co-operation of the American Institute, in the rooms, Berkeley Lyceum Building, 19-21, West 44th Street, New York City, on September 30 and October 1 and 2, 1902. Professor Bateson, of Cambridge University, England, and Mr. George Nicholson, formerly curator of Kew Gardens, London, reached New York on September 24. The proceedings of this Conference, compiled and published in pamphlet or book form, should prove one of the most valuable additions to modern American horticultural literature, along the lines that were taken up and discussed.

**Weather at Temple House Gardens.**

The rainfall at this place, Great Marlow, for the month of September, 1902, was 1.15in. The maximum temperature for the month was 72deg on the 1st and 22nd, and the minimum 34deg on the 18th. There were six foggy mornings during the month; thunder at 6.30 p.m. on the 10th, and very rough winds on the 3rd, 4th, and 16th. The maximum temperature for September, 1901, was 73deg on the 8th and 29th, and the minimum 36deg on the 15th. The rainfall for September, 1901, was 1.18in.—G. G.

**Sussex Weather.**

The total rainfall for the past month at Abbot's Leigh, Hayward's Heath, was 0.54in, being 2.23in below the average. The heaviest fall was 0.13in on the 2nd and 5th. Rain fell on ten days. Total for the nine months, 17.75in, which is 2.52in below the average. The maximum temperature was 73deg on the 1st, 10th, and 11th; the minimum, 35deg on the 19th. Mean maximum, 66.07deg; mean minimum, 47.03deg; mean temperature, 56.55deg, which is 0.36deg below the average. A dry cool month; the wind was in a northerly direction sixteen days. October has come in with a strong N.E. wind.—R. I.

**September Weather at Belvoir Castle.**

The prevailing direction of the wind was N.W. total eight days. The total rainfall was 1.15in, this fell on fourteen days, and is 1.17in below the average for the month; the greatest daily fall was 0.46in on the 10th. Barometer (corrected and reduced): highest reading 30.504in on the 26th at 9 a.m.; lowest 29.425in on the 3rd at 9 a.m. Thermometers: Highest in the shade 72deg on the 1st; lowest 34deg on the 25th; mean of daily maxima 62.73deg; mean of daily minima 46.46deg; mean temperature of the month 54.59deg; lowest on the grass 28deg on the 25th; highest in the sun 125deg on the 1st; mean temperature of the earth at 3ft 55.90deg. Total sunshine 141 hours 25 minutes, which is 13 hours 5 minutes below the average for the month; there were three sunless days. The temperature has again been much lower than usual.—W. H. DIVERS.

**A Royal Visit.**

On the occasion of His Majesty's short visit to North Berwick—from Thursday evening to Saturday morning last week—the Prime Minister on Friday, the 10th instant, drove the King in his motor-car to Whittinghame and through the grounds, on the return journey calling at Tynninghame, the Earl of Haddington's seat. During his stay there His Majesty inspected the gardens, devoting his attention more particularly to the mixed borders in the walled garden, to the "yellow" borders, and to the long Apple-covered walk. Though so late in the season, the garden devoted to bedding plants, and also that to old-fashioned flowers, were bright with bloom. The King, who, it is well known, is a good gardener, expressed his appreciation of the beauties of this Scottish domain, and previous to his departure planted an Oak tree as a souvenir of his visit. An illustrated description of Tynninghame will be found in the issue of this Journal for March 13 of the present year.

### A Birmingham Amateur's Collection.

The collection figured on page 361 is that of Mr. J. Austin, 25, Alder Road, Sparkbrook, Birmingham, who sends a few particulars regarding his flowers. It is seven years since he commenced gardening as a hobby, and has but a small garden—20yds long by 5yds wide, in a thickly-populated district. Mr. Austin is a metal worker, and works fifty-four hours per week in a manufactory situated two miles from his home. He has two glass houses, and started with six Chrysanthemum plants given to him by a friend, and he was so delighted with them that he determined to increase his stock to thirty plants, which he did, and grew them with much care, being ultimately rewarded with a goodly crop of blooms. In the third year (1897) he further added twenty more to the number, this making fifty in all, and yet again in the following year he found space for another fifteen. Mr. Austin joined the Birmingham and District Amateur Gardeners' Association in 1898, and on November 9, 1898, made his first venture as an exhibitor. His success was beyond his expectation; he gained two first prizes and one third prize. This persevering and enthusiastic amateur has since then won many other prizes and special certificates, including a silver medal for a group of Chrysanthemums and foliage plants in pots on November 21, 1900. On the same occasion he gained five firsts and a certificate of merit for a bloom of the incurved variety James Agate. Amongst his list of varieties with which he was most successful, our correspondent names the following Japs.: Nellie Pockett, Madame Gustave Henry, Lady Hanham, Mrs. Barkley, Emily Towers, Lady Ridgway, Mrs. G. W. Palmer; and such incurveds as C. H. Curtis, James Agate, Lady Isobel, Topaze Orientale, Hanwell Glory, Baron Hirsch, and Louise Giles. He has now over 100 plants. Altogether with a total of eighty-three prizes from November 1, 1898, to November 21, 1900, Mr. Austin has a very wonderful and creditable record. Last year (1901) he secured one silver-gilt, three silver, and two bronze medals.

### Too-much alike Varieties.

Societies that are affiliated with the National Chrysanthemum Society, are directed to the undermentioned synonymous or too-much-alike varieties which so nearly approach each other in general appearance that they must not be shown on the same stand.

## A Chat About Bulbs.

It is better to be in good time over making out the bulb order than to delay until late in the season, when the bulbs should have been either potted or planted. There is a tendency on the part of some people to put off sending their order as long as possible. Then, when they receive their Hyacinths or Tulips in an advanced stage of top-growth, and spike and flowers resulting are weak and spindly, or, in the case of Tulips, many may be "blind," they sit down and indulge in long letters to the vendors upon the inferior stamp of bulbs which have been supplied to them.

I am by no means laying down the dictum that all bulbs which have commenced top-growth will of a necessity be unsatisfactory after planting, for I have seen late-planted Tulips succeed fairly well when not placed in the ground much before Christmas. This was an exceptional case, and the safe rule is to get them planted in suitable weather during October.

"Where shall I get my bulbs from?" is a question frequently put and not difficult to answer, so long as the needful cash is forthcoming. Our home growers are producing Narcissi in great quantity and variety nowadays, also other bulbs such as Snowdrops, Scillas, &c. The bulk of the Hyacinths and early-flowering Tulips must, I think, continue to come from the Continent, as we cannot compete with the growers there owing to climatic and soil difference, as well as the greater cheapness of labour abroad in the bulb-growing districts. It is, however, possible to so arrange our orders that the home grower, as far as possible, may benefit.

Those that are not grown in this country the buyer has the option of obtaining through an English firm, or direct from the foreign salesmen or growers, who now have—some, at least—representative agents here. I fail to see much benefit accruing to the buyer for sending across to Holland, as by dealing with any of the well-known houses which advertise in this journal he is sure to receive (so far as may be) value for money.

Roman Hyacinths and Roman and Paper-white Narcissi which are needed for November and December blooming should be ordered without delay, and immediately on arrival ought to be potted or boxed according to the requirements of the grower. It is not necessary to go into cultural details after all that has been written upon the subject in these pages.

The soil used, however, is an important factor for or against success. This should be light, rich, and open. Remember the Dutchmen rely chiefly upon cowdung and sand for the growth of the splendid bulbs they send us. Loam, leaf mould, and well rotted manure in equal parts, well mixed together, with plenty of silver sand is what I generally use, and with fair success.

Do not be in a hurry to get your bulbs housed and out of the plunging material, whether this latter be of ashes, cocoa-nut fibre, or any other medium. Let the pots be full of roots, or nearly so, and then you may feel safe as to the future of the leaves and flower-spikes, after culture being what it should. A sudden transition from total darkness to full light is to be avoided, and must be guarded against by partially shading the blanched growths for a few days. By placing them in the semi-darkness beneath the greenhouse stage, the danger of a check from such a sudden change of circumstances may be avoided.

There has been a good deal of discussion at one time or another as to the relative values of ashes and cocoa-nut fibre as a plunging material. Well, owing to the greater comfort and cleanliness in working amongst the fibre, I should certainly always prefer to use it; but when one cannot get fibre, then the next best thing is undoubtedly coal ashes, and so far I have never discovered any advantage, in the growth of the bulbs, from the use of one more than another.

To return to the subject of buying once more. Some of us have a longing and a desire to attend the autumn sales and see what cheap bargains we can pick up. I have had some experience of buying in this manner, and I cannot say that I have gone away dissatisfied with my purchases. But let not the inexperienced person go alone on such an errand, for he may find himself sent either very full or empty away. That is to say, he may perhaps obtain a great quantity of those sorts he does not want, and which are of little value to him, and of those which would be of use he has none, or very few. It is astonishing how many bulbs, both in number and variety, it is possible to obtain in a guinea collection. For the amateur with small means of accommodation this is an excellent plan of obtaining bulbs; half-guinea collections giving good results upon a smaller scale still.

In an article of this description it is usual, if not always advisable, to say something about Hyacinths in glasses or vases. Candidly, I am not in favour of this method of culture. That it is cleanly and, as a rule, fairly successful, I at once admit, but it seems a little bit unnatural to my way of thinking that the chief organs of supply in the plant's economy should be exposed to the vulgar gaze. Besides this, though at times one sees really fine spikes grown in glasses, they are seldom as satisfactory as

those grown in pots. The treatment is of the simplest. Place the Hyacinths upon the glasses containing sufficient water to touch the base of the bulbs, and keep them in a cool, dark position until growth has become active, when they may be brought to the light of a window. The water in the vases will need replenishing from time to time, and the flower-spikes will need support.

Sound bulbs, rich, light soil of an open sandy nature, with an absence of unduly hard forcing, and giving ample time for roots to form in the plunging bed: here you have all the secrets (which are very open ones) there are in connection with the successful treatment of many of the charming and beautiful things which come under the category of bulbs.—J. W., Newent.

## Hot Water Boilers.

Mr. Louis Pearson (of Beeston) recently read before the Institute of Heating Engineers a paper on "Hot Water Boilers," in which there are several practical hints to those interested in horticultural work. Mr. Pearson shows that old cast iron boilers were both economical and efficient, but they were discarded on account of their faulty jointing and unequal thickness of metal, both of which defects have now been overcome in the modern boilers. He prefers cast iron boilers to those wrought in iron and steel, as the iron boilers can be made in sections, which enable them to be fixed in positions where wrought boilers could not be; it also enables the firebox to be made in deeply corrugated or tubular forms, which not only present a much larger surface to the direct action of the fire, but also tends to check the flow of gases and mix them thoroughly with the oxygen, thereby causing better combustion and economising fuel. Cast iron is also much less affected by oxydisation, which is a great consideration in our climate. Also experiments made by the Philadelphia Scientific Institute show that as a transmitter of heat, cast iron is more efficacious than wrought by over 10 per cent.

However, the chief reason for the greater economy of cast boilers is due to the corrugations and the tubes that can be readily and cheaply placed in the firebox, which not only add very largely to the direct heating surface, but break up and thoroughly mix the gases as they leave the firebox, causing a better combustion. The matter of combustion should be fully considered before designing a boiler of any description or criticising those already made. Heat is caused by the chemical union of various elements, and as there is only one part of oxygen to four parts of nitrogen in the atmosphere, we see the necessity of introducing a large amount of air to insure perfect combustion. Mr. H. J. Mills, in his treatise on boilers, puts the amount of air required to consume one ton of coal perfectly at 120,000 cubic feet. It will be seen from the foregoing remarks the reason for a thin fire giving a much better result than a thick one.

As a rule it is safe to say that the smaller the fuel the thinner the fire should be, and the larger the fuel the thicker, on account of the larger interstices in the use of the latter. It is a common practice to leave the fire door open for a short time after firing, to consume the smoke; this, of course, is wrong, for though you get a large supply of oxygen, yet, as it is at a low temperature, it does not therefore combine properly with the gases. The boiler, too, is being cooled instead of heated, and in the case of wrought iron or steel, it also proves injurious to the plates. Damp boiler holes are often a source of considerable trouble to both heating engineers and their clients, and most of the trouble is caused by engineers trying to keep water out of stokeholes built with flat sides and bottom, by merely laying the bricks in cement, or lining with Val de Travers, without considering the pressure. This is very considerable, for the total amount of a boiler house floor, 15ft by 10ft by 5ft deep, supposing the subsoil water to be level with the top of the brickwork, is 54,000lb or nearly 25 tons. It is, therefore, quite apparent that this must be provided for. With small, medium-sized boilers the simplest and best way is to place the boiler in a wrought iron tank, which should be well tarred, inside and out, and paved with blue bricks. Where the boiler is very large, there should be an inverted arch built under the floor of the stokehole and tied to the walls, which should be at least 14in, and have an inch space left between the 4½in and 9in work, to be afterwards filled with Val de Travers. Even with this plan the workmanship and material must be of the best to ensure success.

### An American Forestry Magazine.

Arrangements have been made for the publication of the "Magazine of Arboriculture" as the official organ of the International Society of Arboriculture, and will have as its distinctive purpose forest perpetuation. The secretary of the society, J. P. Brown, Connorsville, Ind., will act as Editor. The society claims the credit of having induced the planting of over 1,000,000 trees.

## Hardy Peat-Loving Shrubs.

A large proportion of the hardy shrubs which require soil free from lime, and prefer that of a peaty nature for their successful cultivation belong to the great family Ericaceæ, and are characterised by their compact habit, beautiful flowers, and suitability for small gardens. With the exception of the stronger growing species of *Arbutus* and *Rhododendron*, very few grow more than 5ft or 6ft high, while quite a large number make carpet-like masses of less than a foot in height. A peculiarity of the family is the number of genera it contains, which are made up almost entirely of ornamental species, *Erica* and *Rhododendron* being cases in point.

A small garden, situated in a district where peat-loving plants thrive, might be made beautiful and interesting by using nothing else but these plants, and flowers could be had during the whole of the year, except, of course, throughout prolonged spells of frost. As early as January *Rhododendron* and *Erica* flowers are to be found; while a succession is kept up throughout spring, summer, and autumn until various species of *Arbutus*, *Erica*, and one or two *Rhododendrons* take up the running in October, November, or December, and finish up the year with bright coloured blossoms. Of the large number of subjects suitable for planting the following is a selection of the most ornamental.

Although a great many names of *Arbutus* are found in catalogues, the number of really hardy species is three, and these, together with a number of varieties and one or two hybrids, make up a very useful group. As a rule, they form dense shapely bushes, 8ft to 12ft high, but one species, *A. Andrachne*, from the Levant, grows much taller, and assumes the dimensions of a small tree. It is a remarkable looking plant, especially about the end of summer when shedding its old bark. The flowers are white, and borne in large panicles.

Of the whole family, probably *A. Unedo* is the best known. It is a capital subject either for a shrubbery or specimen plant, as it grows into a fine shapely bush 10ft to 12ft high, flowers freely, and bears showy orange and scarlet fruits on pendulous stalks, from which the common name of Strawberry Tree is taken. A number of varieties are in cultivation distinguished by differences in stature, size, and shape of leaves, and colour of flowers. The flowers vary in colour from white to deep rose, and a succession is kept up from October until January. Of the several varieties, some of the most distinct are *microphylla*, *quercifolia*, and *rubra*. Another species not so often met with is *A. Menziesi*, from N. America. Of the few hybrids, that known as *hybrida*, the progeny of *Andrachne* and *Unedo*, is the most distinct.

Leaving this genus, and turning to the large family *Erica*, we find a great many species worthy attention. Conspicuous among them are *carnea* and its variety *alba*, which commence to flower in February and continue in good form until the end of March; *mediterranea* and its various forms, which all flower in spring, particularly the plant known as *hybrida*, an offspring of the two above mentioned species. This commences to flower in January, and continues to so for quite three months, and is without doubt one of the most useful of dwarf flowering shrubs. A summer flowering species of considerable merit is *cinerea*; the flowers of this are rosy red, but there are varieties with white, rose, deep red, and reddish purple flowers. For autumn *E. vagans* and its varieties may be depended on to make a fine display; whilst *ciliaris*, *Mackii*, *multiflora*, *Tetralix*, and *Watsoni* also flower late in the year. In warm localities this list may be lengthened by the inclusion of such fine flowered species as the red flowered *australis*, the white *lusitanica*, *stricta*, *scoparia*, and others. With the Heaths might be included the *Ling*, *Calluna vulgaris*, of which quite a score of varieties exist, varying in habit from dwarf pigmy forms an inch or two high to forms 2ft in height, and in colour of flowers from white to red. Colour of foliage also adds to the varietal list, for there are golden and white variegated leaved forms.

Following this large family come a number of small genera, all extremely interesting, and the majority beautiful. Mention need only be made of *Andromeda polifolia*, with pretty pink flowers; *Pieris japonica*, with large drooping panicles of white blossoms, or *P. floribunda*, with upright racemes of white flowers; *Zenobia speciosa*, a neat shrub with pretty, waxy white blossoms, borne in May and June;

or, better still, its white leaved variety, *pulverulenta*, *Bruckenthalia spiculifolia*, a neat, Heath-like plant, with upright heads of pinkish white flowers; *Bryanthus empetri-formis* and *erectus*, neat plants with red flowers; *Oxydendron arboreum*, a deciduous plant which bears panicles of cream coloured flowers in summer; *Daboecia polifolia*, which from May to November is rarely without blossoms, of this there are forms with white, red, and pink flowers; *Enkianthus campanulatus cernuus*, and *japonicus* should all have a place, as also should *Cassiope tetragona*, *Cassandra calyculata*, *Leiophyllum buxifolium*, and the various species of *Leucothé*.

Turning to larger genera again, our attention is directed to *Kalmia*. Of this three species and numbers of varieties are in general cultivation. The largest growing is *latifolia*. It grows sometimes upwards of 12ft high, but is more often met with less than half that height. It is conspicuous by

layan species can be grown out of doors, but as far north as London very few succeed in a satisfactory manner out of doors. Hardier species, however, thrive, and there are varieties innumerable for all who care to grow them. Some of the hardiest evergreen species about London are *californicum*, *campanulatum*, *catawbiense*, *cinnabarinum*, *dauricum*, *ferrugineum* and varieties, *fulgens*, *Wilsoni*, *hirsutum*, *intermedium*, *Smirnowi*, *racemosum*, *Thomsoni*, and others. Deciduous species, such as *calendulaceum*, *flavum*, *nudiflorum*, *occidentale*, *sinense*, *Vaseyi*, and *viscosum*, together with their progeny, should be found in every garden.

Ornamental fruited plants should be found represented in our peat garden by *Gaultheria procumbens* and *G. Shallon*, and by the varied forms of *Pernettya mucronata*. The list of names mentioned above is sufficiently long to show what a wealth of really good flowering plants is contained in the

**Chrysanthemums: A Birmingham Amateur's Collection.** (See page 359.)

reason of its deep green Laurel-like leaves and pink and white flowers. *K. glauca* is a dwarf semi-deciduous species with rosy-purple flowers; while *K. angustifolia*, a plant which grows from 1½ft to 2ft high, and bears red flowers with great freedom, is one of the gems of the garden. Of this there are several varieties. All three species are North American.

*Ledums* should find a place in our peat garden, the two species, *latifolium* and *palustre*, making shapely white-flowered bushes. *Rhodothamnus chamæcistus* is a gem of gems, and is worth going to a lot of trouble over. It is quite a dwarf plant, coming very near to *Rhododendron*. It is of Heath-like habit, and bears pink and white flowers nearly an inch across. It succeeds best grown in crevices between rocks, and is one of the few members of *Ericaceæ* which is partial to a little lime.

The genus *Rhododendron* contains so much that is good that it is impossible to do more than give it brief notice in passing. In the S.W. counties most of the lovely Hima-

group under notice, and a little consideration will suffice to show how beautiful and interesting a peat garden can be made.—W. D., Kew.

#### English Gardeners in Canada and America.

The transatlantic horticultural papers have recently accorded notices to a number of natives of these Isles, chief among them being Mr. Joseph Bennett and Mr. James W. Dunford. Mr. Bennett is the retiring president of the Canadian Horticultural Society, and was born at Northwold, Norwich, England, in 1858. He served as a gardener at Messrs. Veitch's, Limited, also at Cutbush's and Coombe Abbey, besides at Sir H. Tate's (now Lady Tate's) place in Streatham. He went to Montreal in 1884. Mr. J. W. Dunford was for five years with Messrs. Sutton and Sons, and went to the States in 1888. He started in business for himself in 1894, and now has 45,000 square feet of modern glass houses.

#### Hydrangea Names.

It is not a common error—nevertheless, one not unknown—for persons to designate the well known hardy *Hydrangea*, *H. paniculata*. Nurserymen, observes Mr. Meehan in the "Florists' Exchange," receive orders for this subject, and in nearly all cases assume, correctly, the customer means *H. paniculata grandiflora*—a very different thing. There is in cultivation *H. paniculata*, and a very good plant it is. The flowers on the panicles are not numerous, hence do not weigh down the heads, and each head stands boldly erect on a perfectly straight shoot. It is a good and showy shrub, but not having the mass of the *H. p. grandiflora*, it does not make such a grand showing. But it is a good thing, and is extensively used for massing.

#### Treatment of Box Edgings.

The best time of the year for clipping Box edgings where employed in garden walks is September or early October. Where edgings of this kind have been neglected and plants have grown coarse and strong—and perhaps have become intermixed with weeds and grasses—the most effective method of renewing the edging is to have the whole of the plants dug up and replanted. After being dug up in this manner the old plants should be divided out into pieces, taking care that upon each such piece portion of the roots is allowed to remain. The longer roots attached to these slips should then be cut off and the plants freshly put in along the original line of walk, care being taken in the meantime to have the soil underneath and about them thoroughly dug up and cleared of all roots of weeds or other extraneous growth.

#### *Helenium pumilum magnificum*.

Nearly every devotee of hardy plants is acquainted with the beauty and merits of *Helenium pumilum*, and those who do not know it should constantly be reminded of its value in the garden with its large yellow flowers. These are produced in the greatest profusion on plants running from 2ft to 3ft in height, according to the character of the soil and the moisture conditions. The golden-yellow flowers are about 2in across, and are very beautiful with their high centres and pretty ray petals. In every way superior, however, is the variety named *magnificum*, which is one of the best hardy plants now in cultivation. It is rather taller in growth, though that is not always an advantage. The flowers are also larger and of a lovely yellow shade. It seems to me to flower even more freely than the typical *H. pumilum*, and it is in almost all respects a much finer plant. It makes a capital plant for the exhibition stand, though it does not show to advantage if a big bunch is shown with all the blooms crowded together. It should be loosely arranged with a good length of stem. It can be easily grown in any good soil.—S. ARNOTT.

#### *Helianthus*, Daniel Dewar.

We have Sunflowers galore, and it takes something distinct and good to make a place for itself. In its own way *Helianthus* Miss Mellish is unsurpassable, though its rambling habit is such that it requires to be carefully kept from encroaching on its neighbours in the border. It ought, indeed, to have a place to itself. The same character is the defect of the newer one, *H. Daniel Dewar*, raised a year or two ago by Mr. M. Cutlibertson, of Rothesay, and only now becoming known in gardens. It also has a most encroaching habit, and wants to be placed where it will not eject or smother other flowers. Yet it is worth a good place if only for the sake of its flowers for cutting, for they are to the Sunflowers what the Cactus Dahlias are to the other forms of these popular flowers. The petals are prettily twisted, and the whole appearance of the flower is altogether informal, though, of course, one cannot say that *H. Miss Mellish* is formal either. The flowers of *H. Daniel Dewar* are smaller than those of *H. Miss Mellish* and are of great value for cutting, if this is done before the flowers are too fully open, as they then last much longer in a cut state. As a garden plant, too, this Sunflower is quite effective.—S. A.

#### A New Industry—Crab Jelly.

Probably owing to the deficiency of fruit, including the Apple crop, on the other side of the Channel this year, there is great demand for Crabs and the wild Apples of the hedgerows. Mr. Clifford, T.C., Clonmel, and Messrs. Skehan, Carrick-on-Suir, are catering to meet this want. Whole drayloads at a time have been sent by rail, generally to Liverpool or Manchester, where they meet a ready and profitable sale. The season for Whortleberries and "fralawns," or hurts, for jam making, is over, and that of Blackberries has scarcely arrived. The jams made from those are most welcome to the teeming millions of Glasgow and Lancashire. But is it not to be regretted (says the "Nationalist") we have not small capitalists at home to run such a factory—keep the people employed, and help to realise fortunes for themselves or their shareholders, instead of having all going to our more wealthy neighbours?

#### A Meritorious Annual.

The plant referred to is *Callistephus hortensis*, which grows 1½in to 2ft in height, and is terminated by large mauve-purple flowers, in form like those of a very large single *Pyræthrum*; they are distinctly decorative. *Callistephus hortensis* is the original species from which the numerous varieties of China Aster in cultivation have been produced. Recently we were greatly delighted to see a "lakelet" of the beautiful flowers of this plant sheeting the ground on the fringe of a shrubbery-copse in an outlying and sequestered part of the Royal Gardens at Kew. The plants furnished a most delightful and effective show from a distance, there being tall plants of the quick growing and handsome *Impatiens Roylei* through and amongst them, the whole mass of flowers winding out and in among the Cyprus and Yew trees. Seeds of the Aster had simply been scattered about among the half-bare patches of soil in spring time, and this was the successful result. The feature should be widely copied; it is magnificent.

#### *Aster Thomsoni*.

It is gratifying to see that this pretty Himalayan Starwort is growing in favour, and I am satisfied that those who already possess it will not regret having added it to their gardens. It is now a good number of years since I was introduced to it by one of our most eminent hardy plantsmen, who sent me a plant with some appreciative remarks. It deserved them all, but the plant itself seemed to make its way slowly into other gardens. It is now fairly well distributed, and most nurserymen who grow a collection of such flowers keep it in stock. I have come across it several times in gardens this year, and everywhere it has been spoken of with approbation. Its early flowering is a distinct advantage, as it comes into bloom in July as a rule, though late this year. It lasts well through August, and in colder gardens blooms into September, commencing to flower a little later than in the warmer districts. It grows from 1ft to 2ft high, and has large pale blue flowers of much beauty. They remind one of the blooms of the fine *Aster Amellus bessarabicus*. *A. Thomsoni* is quite hardy, and seems to me to dislike a very dry and poor soil.—A.

#### *Cytisus præcox*.

The Brooms are always favourite plants, and a good collection of the *Cytisuses* and the allied *Genistas* are a most attractive feature of a garden. I do not think, however, that there is any one so much admired as *Cytisus præcox*, a true "cream" Broom, though it opens a very pale yellow. For one thing, it is a splendid doer in dry soil, and it never fails to cover itself with a perfect veil of lovely little flowers. It is one of the small flowered Brooms, so that those who expect to have from it the larger blooms of *Cytisus scoparius Andreanus*, or *C. biflorus* even, might possibly be disappointed. Size is not, however, everything, and both for beauty and for profusion of flower *C. præcox* will more than hold its own with any member of its charming family. I have a fine plant in my garden which increases in size and beauty every year, and is a perpetual object of admiration when it is in bloom. It is so fine that one will not grudge to divert the path on which it rather encroaches to secure an even better display in early spring, for it is one of the first of the genus to bloom. After flowering it is cut well in, but requires no further attention. It was raised at Warminster, in Wheeler's Nursery, and is supposed to be a hybrid of *C. purgans* and *C. albus*.—R. N. T.

### An Abnormal Pear.

Referring to the abnormal Pear shown before the Scientific Committee of the Royal Horticultural Society on September 23, I recently saw a fruit, which appeared to be one of the Bergamottes, bearing a circlet of small leaves. The upper portion of the Pear was round and flattish, shrinking suddenly to a waist-like depression, then swelling again down to the base. The leaves were growing from the waist. The Pear also bore two eyes other than the one at the base. These were located about half way up.—W. A. T.

### Red Spider and XL All.

Having used XL All vapourising compound since its first introduction to the public, I myself have never known it to kill red spider. But to show that "H. D." is not the only one who has succeeded in killing it with XL All, I will briefly relate what a shrewd and clever gardener said to me a few weeks ago, and perhaps if this note comes under his notice he may give the readers of the Journal the benefit of his experience in its use on that occasion. I can give no details, but will merely say that he succeeded in killing the spider by giving a second fumigation immediately the contents of the fumigators were exhausted, which second filling took place about nine at night. In the morning every spider appeared to be dead.—J. EASTER, Nostell Priory Gardens.

### Garden Inventions.

There is no doubt that a great number of garden tools and appliances are capable of considerable improvement. But, as an inventor in a small way myself, I would advise any gardener, who is no longer young, or is apt to expect too much, or be irritable at disappointment, to leave the question of patents, or "bringing out" his invention alone, save for his own use. It is a rare thing for the actual inventor of any improvement to make much profit by his discovery, and not a few have sustained serious losses. It seems rather cowardly advice to give, and is not meant for the young and energetic, with a good deal of commercial knowledge and aptitude, plenty of time to spare, and plenty of money to risk; but for those who are short of these requisites I would advise selling the idea as soon as possible to someone who has (or thinks he has) got them.—W. R. RAILLEM.

I have read with great interest Mr. J. Barkham's letter (page 320), which shows, as I had expected, that there are men in the gardening profession with fertile brains, capable, if given the necessary encouragement, of improving most of the gardening appliances which we have in use at the present day. "Necessity is the mother of invention," and although I cannot claim to be an inventor myself, owing, perhaps, to my not having the good fortune of being "born that way," I think all the help possible should be given to anyone possessed of this very special gift, for no one will deny that it is a gift, instead of having, as in "J. B.'s" case, to hide their light under a bushel, as it were. "Squib," in his letter on the same page, puts forward three very novel suggestions having for their object the improvement of the spade, barrow, and rake respectively, and these on paper may look very well; but it would be interesting to learn how they would work out in actual practice. Some of the most important qualifications an invention should possess before being placed on the market are (1) efficiency, and (2) durability, each most important factors in any garden implement. At the same time, it should be as neat and as light as possible, having due regard for the work which it is intended to perform. Above all these, it should also be easily worked; and inexpensive. It should also be borne in mind that the simpler it can be made, the more likely it is to take on when placed before the public. It seems hard indeed, when a person has succeeded in perfecting some appliance in daily use, that he should be denied the just reward which his skill and ingenuity deserve, owing either to lack of the necessary funds or influence. I quite agree with "J. B.'s" suggestion for an article or series of articles written by an experienced man, showing the best way to patent an invention and place it on the market in a proper manner, so as to attract the attention of all those whom it would be most likely to benefit. An article of this description would, I believe, be read with great interest by all gardeners and nur-

serymen. Most inventors are very modest about their achievements, and very often only those living in the immediate neighbourhood are aware of an inventor's discovery. This may be accounted for in two ways: firstly, owing to the expense incurred by having the patent protected, and the cost of advertising, which would be a great drain on a gardener's all too slender purse; secondly, even if he consented to this initial outlay, there is the risk of ultimate failure and disappointment, owing to his invention not meeting with the approval of the public. The only remedy that I can see in this case is to submit the invention to some large horticultural sundriesman, who might be induced to buy it outright and take all the risks himself.—H. MUNCY.

### Leaf Decoration.

Respecting the use of leaves referred to on page 303, may I suggest another interesting amusement, viz., making plaster casts? A plaster worker explained the process to me, and for studies the effect is very fine. An examination of a leaf will show that the veins on the reverse side are identical with the front, with the difference that they are raised instead of being depressed. It naturally follows that a casting of the back gives an impression of the front appearance. Selected leaves of good form should be chosen, and fastened securely to a board, face downwards. A small quantity of plaster of Paris should be mixed to the consistency of thick cream, and this dipped out with a spoon and placed carefully all over the surface of the leaf, in a very thin layer. So soon as it has set, another lot should be mixed and added on top of the first, repeating until the plaster is sufficiently thick to bear handling. When well hardened, remove from the board and detach the leaf. Should it have stuck, careful soaking with hot water will remove it. This trouble may possibly be obviated by applying a thin coat of oil, but it probably would affect the plaster, so I have not tested it. A fine file, or a penknife will trim the outer edge to the natural form. These castings may be used for numerous purposes, and a colour artist might further improve them by painting the natural tint.—SQUIB.

### Fumigating against Scales.

I have had for some thirty years past a varied experience in the treatment of scale on plants, and have not, until very lately, discovered a really effectual destroyer. I have found it most difficult, especially at busy times, to keep the trees in a large Camellia house clean. Last autumn I decided to give Messrs. A. Cross and Sons' "Necros" vapourising powder a trial, and for this purpose selected various plants affected with different kinds of scale. After fumigating, I left the plants until morning, when I carefully examined them, and found they were quite uninjured. I then gave them a thorough syringing. In about a month's time I repeated the treatment, this time with the strength of the liquid increased by one-half. After letting another four weeks elapse I decided to give a third application, this being more as a precautionary measure, as my difficulty has always been in entirely destroying the scale. This experiment has since proved quite a success, the plants being now perfectly free from scale and in a healthy condition. I have had equally good results on a larger scale in the Camellia house mentioned above, where, I am pleased to say, there is now not a trace of scale left. Since these experiments I have repotted some Orchids which were in the same house when I made my first trials, and I was very agreeably surprised to find them almost completely free from woodlice. I can only attribute this to the results of the fumigation, as the pots have previously been infested.—W. T. KIRPS, Head Gardener, Walton Lea, near Warrington.

### Perpetual Fruiting Strawberries.

Last year I nearly decided to give up St. Joseph, and grow St. Antoine de Padue alone; but eventually I retained a bed of the former, though I made no fresh plantation of it. This was fortunate, as my St. Josephs have been for a month, and still are, simply one mass of flowers and fruit. They have been the astonishment of all who have seen them, although these same plants were heavily cropped in the summer, having ripe fruits a week sooner than any variety in the neighbourhood. Since the summer, when they bore well, my St. Antoine plants have been a failure, being badly struck with mildew. There has been, and still is, plenty of bloom, but the stem of each truss is affected sooner or later, and the fruits spoiled. I should be glad to know of a cure or prevention for this. Is not Royal Sovereign, one of its seed parents, rather liable to it, the leaves spotting and dying off early in the autumn? This does not matter so much with a summer bearer, but is fatal with a perpetual. I am strongly of opinion that St. Antoine should be crossed back again, into St.

Joseph, or one of the other first cross perpetuals, to gain shorter and more sturdy leaves, to increase the perpetual tendency, and give greater hardiness. I am more than ever convinced that some form of perpetual is the Strawberry of the future, and that the end of those which bear only once a year is certain to come sooner or later; but the perpetuals want high cultivation, care and attention. It is necessary to entirely suppress all runners which are not wanted, so soon as possible; and this at certain times should have almost daily attention. At this time of year some form of wire support for the fruit, to keep it off the ground and exposed to the sun and air, is equally necessary. Wasps, and even bees, were a great nuisance at one time. Strawberries have such a strong scent that they prove very attractive. In the fine weather three weeks ago, St. Joseph simply swarmed with wasps, bees, flies, and hornets, and proved an absolute protection for my outdoor Peaches close by on a wall, which had not any insect marauders.—W. R. RAILLEM.

## Lilies of the World.

(Continued from page 333.)

**AMERICAN LILIES (GENUS LILIUM).**—Of these there are some thirty wild species, and those I describe will be hailed by the amateur gardeners of the Cape Peninsula, especially on the Newlands, Claremont, and Rosebank sides of Table Mountain. They are mostly moisture-loving Lilies, and at the places I have named the conditions that will ensure their successful culture are perfect.

**Canadense flavum** (a beautiful species, with golden-yellow flowers, which are freely spotted purple inside), height 3ft. **Canadense rubrum** (flowers red on the exterior and spotted black in the interior), height 3ft. **Superbum** (if my recollection is correct, old John Parkinson, in his "Garden of Pleasant Flowers," 1629, illustrates and describes *L. superbum* as *L. Martagon imperiale*, and well does it deserve the name. It attains a height of 7ft, and carries from twelve to twenty handsome flowers on a stem. The flowers range in colour from rich orange to crimson, all beautifully spotted.

**Pardalinum** (this species represents some wonderfully beautiful varieties, ranging in height from 4ft to 7ft, and even taller when the conditions are favourable, and producing great heads of lovely flowers). **Pardalinum type** (flowers bright scarlet, shading to rich yellow, freely spotted purple-brown), height 6ft. **Pardalinum Bourgoei** (large, beautiful flowers, bright crimson colour, shading to yellow and spotted maroon), height 6ft. **Pardalinum Michauxi** (flowers crimson-scarlet, shading to yellow, spotted maroon; flowers later than the other species of *L. Pardalinum*), height 5ft. **Parryi** (flowers citron-yellow, spotted chocolate-brown; a magnificent species), height 3ft.

The foregoing species of American Lilies to be seen to fullest advantage should be grown in the moist soil of a *Rhododendron* bed, when the effect of their mass of beautiful flowers is simply wonderful. Planted amongst lumps of sandstone and kept moist, might do as well as amongst *Rhododendrons*.

**Humboldti** (this grand Lily was collected by the great American traveller and plant collector, Mr. Roezl, on the birthday of the great Humboldt, and was named after this world-famed naturalist; flowers large, golden-yellow; of great substance and very showy. A well-grown specimen will give from twenty to thirty beautiful flowers on a stem), height 5ft. This species is found to do best in a moist soil, but not so wet as those above named; still that it does not object to water is proven from the fact told to me by Mr. Roezl that he had to roll up his shirt sleeve to get the bulbs out of the water.

**Parvum** (very distinct and showy; small flowers of bright orange-scarlet colour; freely spotted), height 4ft. Takes the same treatment as *L. Humboldti*. **Bolanderi** (a beautiful species from Oregon, with elegant bell-shaped deep crimson flowers; spotted maroon; moderately moist soil suits it best), height 1½ft. **Columbianum** (the flowers of this species resemble *L. Humboldti*, but much smaller; they are very graceful and fragrant, and of a brilliant orange colour, spotted crimson; same treatment as *L. Humboldti*), height 3ft.

Lilies (genus *Lilium*) from India, Burmah, and Nepaul. Number some seventeen species, all of great beauty, and most likely all would suit South Africa, but I will only

describe three species, as the others have up till now not been a success in Europe. If my friends in South Africa like the sample I ask them to commence with, I can leave time to settle the question of the fourteen other species being tried. **Nepalense** (flowers golden-yellow, tinged inside at base of petals deep purple; handsome funnel-shaped flowers), height 3ft. **Sulphureum** (syn. *Wallichianum superbum*). When in Auckland, New Zealand, 1900, I saw in Mr. Ball's garden this really handsome Lily, and a noble sight it was. Height 5ft to 6ft, with a coronet of seven long white flowers surmounting a sturdy stem. I had a letter recently from Mr. Ball informing me that the Lily this year had fifteen flowers.

At another garden in Auckland I saw the same Lily behaving in a similar manner, and with a considerable progeny of all sizes. The owner expressed a desire to sell some of them, and I undertook to sound the Lily's praises as I travelled this progressive and aggressive wonderful country, "the home of the brave and the free of the Southern Hemisphere." I had a letter of thanks recently from the owner referred to, informing me that he had sold well on to £20 worth of the bulbs of *Lilium sulphureum* to the persons I had recommended it. Now this man a few years previously had brought a bulb for 5s. 6d. So say no more about the gigantic profits of the Cape Town Cold Storage Company. Here is a record-breaker for you in Lilies, and he expects to reap an annual revenue from this original investment of 5s. 6d. He let me into the secret of increasing the bulb, so pardon my not taking you into my confidence, as I promised not to spoil his market by letting others know how he worked his diamond mine.

**Giganteum**, the noblest and most gigantic of Lilies. Some forty years ago I first made the acquaintance of this grand Lily, and it got so impressed on my mind that I can see it as I now write about it. I had paid a visit to the late Sir Morton Peto's fine old garden, near Lowestoft, England, and wandered about with Mr. Bradley, the gardener, who had a trick of keeping visitors in conversation till some surprise he wanted to give came in full view, when we would say, What do you think of that, of this, and the other thing? And so we went along chatting and admiring, till we arrived at the long conservatory, where he threw open the door, and revealed a tropical profusion of foliage drapery, while at the end stood two sentinels reminding one of Gog and Magog at the Mansion House guarding the entrance to the house. "What have you got there, Mr. Bradley?" was my surprised inquiry, pointing to

A fasciated *Lilium auratum*.

(See page 357.)

the sentinels. Waiting till the surprise was over, he replied *Lilium giganteum*.

The next plants were in the gardens of the Hon. and Rev. Boscawen, Cornwall, who had grown this Lily from its introduction, and never was without a supply of flowering plants in his garden. The third successful grower of this majestic Lily I knew was Miss Jekyll, in her beautiful garden at Godalming. She grew it to perfection, and as is the wont of this wonderful lady, who never seemed happy unless all the world participates in what gives her pleasure—the Lily bulb flowers but once, but leaving a numerous progeny—at considerable trouble she not only had *L. giganteum* figured in "The Garden," but showed also in the illustration how it was reproduced, and how easily it could be made an attraction in all gardens. Those who may chance to have "The Garden" bound up will find the illustration some twelve or fifteen years back. Monster bulbs of this Lily are offered for sale; it is well to try such, but those the size of a Pear will be found the most successful. Monster bulbs are apt to go back, back, till they become small before they make a serious attempt to work for a flowering size. Height, 7ft to 10ft, long white funnel-shaped flowers stained purple.—PETER BARR, V.M.H., Cape Town.

(To be concluded.)

## Book Notices.

### Thompson's Gardeners' Assistant.\*

This is the concluding volume of the revised and remodelled edition, there being six in all. It is devoted to remarks on the crops usually grown in the kitchen garden, and is thoroughly abreast of the times. Users of this volume will discover notes on many vegetables and salads that are rarely cultivated in British gardens, yet there is little reason why they should not be. Amongst the lesser known plants on which information is supplied are the Lentil, so largely cultivated near Paris, and which succeeds in warm southern parts of England; the Liquorice, whose fleshy roots provide a sweet, mucilaginous juice, extracted by boiling, and is much esteemed as an emollient in colds. Large quantities are grown at Mitcham, in Surrey, for the use of druggists. Then there are notes on Good King Henry (*Chenopodium Bonus-Henricus*), whose shoots are edible; and the Hop (*Humulus Lupulus*), which is also cultivated in some gardens for its tender shoots, these being substituted for those of Asparagus.

Indian Corn or Maize (*Zea Maize*) we seldom meet with, though a gardener at Sydenham, and known to us, makes a point of growing a considerable quantity each year for use. It is imperative in his case, for his employers are Americans, and insist upon having it. Marigold, too, though seen in the flower borders, is but sparsely employed, and yet the flowers may be gathered when full grown and dried in the shade, to be kept for winter use. In cookery they are used for flavouring soups. The three species of Mint—the Spearmint, Catmint, and Pennyroyal—are defined, and their culture described. Nor is the garden Nasturtium (*Tropæolum majus*) omitted. It is referred to on account of its leaves being eaten as a salad. The Morel, an edible fungus, and the Truffle are both of them figured and described, thus adding to the value and completeness of the work.

Before concluding this review of the lesser known "vegetables" we would refer to Orach, or Mountain Spinach, whose leaves, of course, are used as a substitute for the usual Spinach; also to *Oxalis crenata*, whose little bulbous roots are consumed largely in warmer countries than England. Perhaps these Islands are not favourable enough for its general culture, though the warmer parts would doubtless suit it. The tubers are, however, somewhat acidulous. It is better known as a decorative plant for the greenhouse.

Under Parsley a note is devoted also to the Fool's-Parsley (*Æthusa Cynapium*), which is quite a distinctive genus, but the note sounds a warning in reference to the very poisonous nature of the *Æthusa*. Other plants included are Purslane, Quinoa, Rocambole, Tree Primrose, *Tropæolum tuberosum*, Garlic, Samphire, and Savory.

Coming to the indispensable crops of the kitchen garden, their treatment is very fully dealt with, and various systems are described. The Onion monopolises seven pages, exclusive of one full page plate, and another page illustrating eight forms and varieties. The Welsh, Egyptian, Madeira, Potato, White Spanish, and other sorts are figured and described, while the classified list of Onions exhibited at a Vegetable Conference held

by the Royal Horticultural Society at Chiswick, in September, 1899, is printed in this volume. We note the omission of a very excellent and now proven variety, namely, Dobbie's Golden Ball, which ought surely to have found a place.

The Potato deservedly receives very considerable attention, and Mr. A. W. Sutton's paper on the cultivation and improvement of this esculent is reprinted from the nineteenth volume of the Journal of the Royal Horticultural Society (1896). A figure of sprouted tubers, for planting, is furnished, and the method of attack and growth of the *Phytophthora* or Potato-disease fungus, together with a photograph showing the effects of sprayed and unsprayed Potato plots, are also included. The description of this fungus attack and methods to combat it are described in the text. We notice an error in the fifth line from the bottom of the first column on page 490, where the address of Mr. Robert Fenn is given as "Southampton, Berks," instead of Sulhamstead, Berks.

The names of vegetables are appended in lists by themselves in English, French, and German, and may be useful in certain directions. The calendarial directions for garden operations throughout the twelve months in the fruit and kitchen gardens cannot but be useful, and is excellently drawn up, and the concluding chapter on "Collecting, Storing, and Packing Vegetables," will be received with satisfaction by those in large gardens, or market establishments especially. A well prepared index is furnished, though the numbers of the divisional volumes before that of the number of the pages in place of the Roman figures which represent three separate div.-volumes, would have facilitated the act of reference. Three coloured plates are included in this volume. In all respects the new edition is excellent, and is well within the purchasing means of gardeners, to whom we highly recommend the work.

### European Fungus Flora: Agaricaceæ.\*

A well-bound book of 274 pages (5in by 7) inclusive of an alphabetical index of species. It is a compilation for the specialist, and devoted to the Agarics of all Europe.

Observations extending over a period of twenty years, has led Mr. Massee to the conviction that familiarity with the Fungi and literature pertaining thereto, of one country alone, leads to a false impression as to the significance of the term "species." "It conveys the idea," says the author, "that species are much more sharply defined than proves to be the case, when the entire Fungus Flora of Europe is included. In all large genera common to European countries, the continental species can be sandwiched between British species."

In the work before us, the idea is to give the essential characters of each species as presented by pileus, gills, stem, and spores respectively. For reasons that are given, the species of Britzelmayer are not included.

"In Cooke and Quélet's *Clavis Synoptica Hymenomycetum Europæorum*" (1878), 1,943 species of Agarics are recorded as European, and of these 939 are given as British. The present work includes descriptions of 2,750 European species, of which 1,553 are British, a number considerably in excess of that recorded for the species of any other European country."

### Garden Cities of To-Morrow.†

This book is written to explain the arrangement, the making, the system of revenue and expenditure and general administration of the proposed Garden City—a model city, with abundance of open avenues, boulevards, gardens, and parks; the manufacturing all placed on the outer fringe, the circular railway being confined to that part too, and only a very few buildings in the centre, these being a library, town hall, hospital, theatre, museum, and concert hall. The scheme has gone so far, that a syndicate has already been formed with a considerable subscribed capital to put it into practice. To go into figures would necessitate far too much space, but the book is within the reach of everyone who has the least interest in the subject. However desirable it may be to have garden cities, we are persuaded that they will never exist, or not for long, on the plans laid down in this book. In every great centre of population we find the death-rate decreasing since more perfect sanitary measures have been in vogue during the last twenty or thirty years. Also in every city there is a growing desire for open spaces and wider streets, which desire is largely being gratified to the increasing healthfulness of these towns and their inhabitants. Excessive rents have long ago caused certain manufacturers to remove their places of industry from city to country, and what it costs them in one way is recompensed in another. With speedy electric and motor traction in full realisation, distance is now discounted, and having even the promise of a practicable aerial system of transit, the town and country cannot be longer socially disconnected, but should become more and more interdependent.

## Figs under Glass.

### Early Forced Trees in Pots.

Trees intended for affording fruit at the close of April or early in May will now need dressing with an insecticide, paraffin emulsion 8oz to a gallon of water answering, adding  $\frac{1}{2}$ oz of liver of sulphur, and applying it in a tepid state with a brush, being careful not to injure the points of the shoots or rub off the embryo fruits. Very little pruning will be necessary, the trees having been regularly stopped during the season, but if the growths are too crowded and irregular they may be thinned to render the trees symmetrical, but the shoots must not be shortened, or the first-crop Figs will be cut off. The house in which the trees are forced should have the wood and ironwork washed with hot water, whitewashing the walls with hot lime and a handful of flowers of sulphur to a pailful. A mild bottom heat is almost a necessity to a successful swelling and perfecting of the earlier crop, the pots being raised upon loose bricks, pedestal fashion, in the positions they are to occupy in the bed, and the pit filled with Oak or Beech leaves pressed firmly. The depth of the pit needs to be about 3ft, with a mixture of stable litter and leaves, one-third of the first to two-thirds of the latter; for leaves alone the depth should be 4ft to 4½ft.

Care must be taken to avoid overheating, not allowing the temperature about the pots to exceed 65deg until growth takes place. The trees should consist of early and reliable first crop varieties, Early Violet and St. John's being small-fruited and earliest, Brown Turkey and White Marseilles following, and are large fruited, and be started about the middle of November, bringing them forward very gently, keeping the house close and moist by sprinkling twice a day in bright weather, employing fire heat to maintain a temperature of 50deg at night, 55deg by day, and with sun heat 60deg to 65deg. The soil must be brought into a moist condition by needful watering, but not making it sodden.

### Early Forced Planted Out Trees.

The trees should now be untied from the trellis, and the needful pruning effected. Those with the roots restricted to small borders will only require to have the shoots thinned where too crowded, cutting back growths extended to the limits of the trellis and useless for fruit production, so as to allow space for the successional growth. Trees that have not the roots restricted will require cutting back at the upper part of the trellis, allowing room for the extension of the lower fruitful branches, but luxuriant trees should be root-pruned, or the cutting out of growths will only tend to render the trees more unfruitful. The trees should be washed with an insecticide as advised for those in pots, and be secured to the trellis loosely. Cleanse the house thoroughly, remove the loose soil, remains of mulching, point over with a fork, and apply a surface dressing of fresh loam and sprinkle over that 4oz per square yard of a mixture of three parts dissolved bones, two parts nitrate of potash, and one part sulphate of lime, and on that a light mulch of partially decayed manure, lumpy, yet short. Give a good watering, ventilate freely at all times, except when frost prevails, then keep closed, and turn on heat to exclude frost.

### Succession Houses.

The trees are not ripening the wood well in some cases, and it would be wise to turn on the heat in the morning, and admit air only to induce a circulation, throwing the ventilators open at night, the heat having been turned off at midday. This will assist the maturation of the foliage, but any unfruitful trees must be root-pruned and the roots restricted to moderate sized borders, and are then more manageable and fruitful with the roots confined to limited space than when having an unlimited rooting area. Prune the trees when the leaves have fallen, cleanse the house, put everything in order. Dress the trees, especially those that have been infested with insects, with an insecticide, it always being good policy to do this as preventive of attack. Keep the house cool and dry, yet exclude severe frosts.

### Late Houses.

Excessively luxuriant trees should be lifted and root-pruned, as advised above. Trees in unheated houses ought to be given free ventilation, and when the leaves fall wash the trellis well. Have the branches tied together in convenient bundles and made safe from frost with some straw or fern over them, encasing the bundles in mats. In heated houses this is not necessary, but the trees in these must not be exposed to severe frosts or they are liable to be injured, therefore a little warmth will be necessary in severe weather. Trees in cool houses should have the roots, especially at the collar, protected by a covering of dry material.—GROWER.

## Societies.

### R.H.S., Scientific Committee, Oct. 7th.

Present: Dr. Russell (in the chair); Messrs. Worsdell, Saunders, Worsley, Odell, Hooper, Drs. Cooke and Rendle, Professor Boulger, Revs. W. Wilks and G. Henslow (Hon. Sec.).

*Crotalaria Species*.—Mr. Wilks exhibited a flowering branch of a species raised from seed received from Uganda. It closely resembled *C. Cunninghamii*, from the neighbourhood of the Gulf of Carpentaria in Australia. Dr. Rendle undertook to examine it for identification.

*Effects of Hail in Kent*.—Mr. Wilks also showed stems of trees of which the bark had been ripped open in considerable lengths by the hail of the late storm. The wood was exposed as the bark curled backwards. It was received from Mr. Woodward, of Teston, Kent. It was recorded that six tons of hail was found in the basement of a house after the storm.

*Fir and Cryptococcus*.—Mr. F. Lloyd, High Sheriff of Buckinghamshire, sent a bough infested by this insect. The tree had died after four years' attack. Mr. Saunders undertook to examine and report upon it.

*Mushrooms and Mites*.—Mr. Gaut, of Leeds, sent some specimens badly attacked by mites, which, with their eggs, were very observable. They are said to be wholly destroying the crop. Mr. Saunders examined them, and reports as follows: "The Mushrooms are badly attacked by one of the 'bulb mites,' *Rhizoglyphus echinopus*. I do not see what can be done to destroy them but to clear out the whole of the Mushrooms and the top soil of the bed and begin afresh. Any method of killing the mites would certainly destroy the Mushrooms; soaking the upper part of the bed with boiling water would kill the mites, but it would equally kill the Mushrooms, and most probably the spawn. Before making a new bed I should wash down the walls or woodwork that had in any way come in contact with the bed with paraffin emulsion or paraffin mixed with water, one part of the oil to twenty of water, or with boiling water."

*Vine Leaves Burnt*.—Leaves of Madresfield Court Vine were received from Mrs. J. B. Wood, Henley Hall, Ludlow. No fungus could be detected. It was suggested that the appearance was probably due to the effects of the sun through the glass on the leaves when they were wet.

*Begonia Leaves Diseased*.—Leaves were received from Mr. C. Newington, of Oakover, Ticehurst, Sussex. An examination by Mr. Saunders revealed no insect pest; but Dr. Cooke remarked that the peculiarity of the disease occurring along the ribs and veins was very suggestive of *Gloeosporium*, so that it might be an incipient stage of that fungus; such being the feature of this disease of leaves of the Plane tree.

*Chlorosis on Palms*.—Mr. Odell exhibited seedlings of *Kentia*, showing the yellow, unhealthy leaves, taken from a batch of some thousands of seedlings, of which only a very small proportion were affected. A plant of *Kentia* submitted to the committee in February last (with five others) were in same state as seedlings shown, but when grown in a cool house with little shade, and potted in soil containing a trace of iron, the leaves developed the ordinary colour. Mr. Odell added that *Kentias* and *Seaforthias* (*Archontophoenix*) seem more subject to chlorosis than such genera as *Cocos* and *Rhapis*.

*Germination in Amaryllids*.—Mr. Worsley read a paper on this subject, which will appear in full in the Journal of the Society with illustrations. The author observes: "That it is possible for two embryos to exist in one seed of *Hymenocallis concinna* (Baker, sp. nov.). I believe it to be unique in the literature of these plants. The minute threads by means of which the ovules adhere to the base of the style (placenta) and constitute the only direct communication with the stigma, would seem to be so arranged that the whole of the ovules would become impregnated contemporaneously, and probably instantaneously, on the adhesion of a sufficient number of virile pollen grains to the stigma." Of these *Amaryllids*, with bulbiform seeds, he observes: "Such plants have a fixed number of ovules (six) and a fixed number of seeds (subject to very small fluctuation), yet there is often a great dissimilarity between the number of seeds and of ovules." In the above plant the number is four. "I believe that we must seek in the structure of the tissues below the ovary the cause of such limitations. It would seem as though the carriage of nutriment to the embryo from the bulb of the parent was either limited by the nature of such tissues to a certain number of channels, or that all the nutriment became, after impregnation, quickly diverted to the strongest embryos, and that the rest suffered from strangulation or starvation." He then refers to the great variety of sizes, the unequal vigour and vitality in the seeds. After alluding to the difficulty, if not impossibility, of "diverse impregnation" in support of his theory of simultaneous impregnation of all the ovules, Mr. Worsley proceeds: "From this it would appear as though a single pollen grain were capable of impregnating over 100 ovules, such as exist in the ovary of *Hippeastrum*; yet I do not think we are justified in asserting this to be an ascertained fact."

He then alludes to the well known fact of different degrees of impregnation of the ovules when hybridising plants is performed, and adds: "These experiments tend to suggest that, beyond the one act of excitation, or instantaneous impregnation, there remains some further function for the male germs to perform, which is improperly or only partially done by foreign pollen grains." In the case of *Hymenocallis concinna*: "The original process issuing from the seed is duplicated, and each process is terminated by a bulb in process of formation." This he refers to two embryos having been formed within the embryo sac, and suggests that one pollen grain may contain more than one fertilising sperm-cell, and so impregnate many ovules. The author then refers to the curvature of the "process" as it issues from the embryo, of which he says its principal function is not that of a root.

**Abnormal Onion.**—Mr. Healey, of Hampton, Middlesex, sent a very curious formation. The Onion was well formed below, and bore a green stem of some 6in in length, but terminated by another Onion, also well formed. It was thought that it replaced the flowering bud, this having been broken off, but an examination by section showed that such was not the case; so that it arose from the replacement of the flower bud by a true bulb. Mr. Healey adds: "The sheath around the Onion below, over the second bulb, and right to the top, was continuous; and when pulled up the sheath was not even broken."

**Physianthus Catching Moths.**—Mr. Henslow showed flowers of this American Asclepiad, often cultivated at Cape Town, nearly every flower of which had caught a small grey moth by its proboscis, being nipped between the anthers. They either died of starvation, or, as was frequently the case, were carried off by bats.

### Birmingham Gardeners.

The opening meeting of the autumn session of this association was held recently, when the president (Professor W. Hillhouse, of Birmingham University) gave an instructive and interesting verbal lecture on "The Theory of Root-Pruning," which was illustrated with a series of diagrams relative to the structure of the roots of trees and their assimilation of water and other liquid nutriment. Prizes had been offered for collections of Grasses correctly named, for which, however, there were no exhibits. At the next meeting, October 20th, the subject will be "The Evolution and Improvement of Fruit," by Mr. Lewis Castle, superintendent of the Duke of Bedford's experimental fruit farm, Ridgmont, Bedford.

### Woolton Gardeners.

Mr. R. Todd, of the Woolton Wood Gardens, occupied the chair at the first meeting held in the Mechanics Institute, when an excellent lecture on the barometer was given by Mr. W. S. Patey, a frequent attender at their meetings, and a gentleman who stood high in the recent examination of the R.H.S. A feature of the meeting was the large number of teachers who were present at the invitation of the committee, the lecturer experimenting and showing diagrams which proved most interesting. Mr. T. Carling and Miss Hindle proposed and seconded the vote of thanks, Mr. W. W. Gamble and Mr. R. G. Waterman supporting the vote. Miss Wright, on behalf of the teachers, thanked Mr. Patey and the committee for their kindness.—R. P. R.

### Bristol Gardeners.

The opening meeting of this association was held at St. John's Rooms, Redland, on Thursday, October 9, under the chairmanship of Mr. E. Binfield, Old Sneed Park. On this occasion Mr. Brooks, of Messrs. Garaway's Nursery, Clifton, gave an interesting lecture on the great fruit show of the Royal Horticultural Society, held at the Crystal Palace, London. He dealt with the numerous exhibits of former years, and compared with those of the present season, showing the effects such a summer we have just experienced must have on the fruit supply of the British Isles. He emphasised the fact that gardeners would find it an excellent object lesson to visit these shows at intervals, thereby gaining a knowledge of fruit grown in the different counties and under different conditions. He argued that gentlemen would find it to their advantage to send their gardeners to inspect the exhibits at this, the finest fruit show of the British Isles, where they would see the best quality, and return home with an ambition to grow fruit equal to that seen at the show. Comparing the fruit of this to the fruit of last season the lecturer remarked on the absence of many of our leading exhibitors, which proved how disastrous our sunless summer had been on our fruit crops, and where 4,000 dishes of fruit had been shown in former years only 1,000 were on the tables this. Mr. Brooks also gave some very useful information as to the packing of fruit, and mentioned the mode adopted by leading exhibitors. A good discussion followed Mr. Brooks' lecture, and he was cordially thanked. The prizes for the evening were for two bunches each of black and white Grapes. For black the first went to Mr. N. C. Dobson (gardener, Mr. Thoday); Mr. Francis Taggart, F.L.S. (gardener, Mr. Binfield),

A Pot-grown Banana. (See page 357.)

securing first for Muscat of Alexandria; while Mr. W. A. F. Powell (gardener, Mr. Raikes) was here an excellent second with Golden Champion. Lady Cave (gardener, Mr. Poole, F.R.H.S.), obtained a Certificate of Merit for a collection of ornamental Gourds. The judges also awarded a certificate to Mr. J. M. Kitley, Littleover, Derby, for three bunches black Grapes, notwithstanding they were very much spoilt in transit.—H. K.

### Cardiff Gardeners.

The opening meeting of the association took place at the Grand Hotel on Tuesday, October 7, Mr. F. G. Treseder presiding over a very large attendance of members. Mr. J. Basham, jun., fruit grower, Bassaleg, Mon., gave an interesting lecture on "Fruit Culture, Past and Present." By way of enhancing the lecture, several dishes of very fine examples of culinary and dessert Apples and Pears were staged. The lecture was one full of interest, dealing with Apple culture from the twelfth century to the present time, giving full details regarding the best methods to adopt to ensure successful results. The debate was of an appreciative character. A first-class certificate and a special vote of thanks was awarded Mr. Basham for his collection of thirty-five dishes of fruit. Competitive Classes:—Class 1, for best dish of culinary Apples, and ditto dessert (five fruits to form a dish). Mr. P. Malpass won with good fruit of Warner's King and Cox's Orange Pippin; Mr. Curtis second, and Mr. Murton third. Class 2, for the best dish of dessert Pears (five fruits to form a dish). Mr. P. Malpass first with good Williams' Bon Chrétien, and Mr. Collier second with Pitmaston Duchess. Several competed in both classes. Messrs. Basham and Son were the adjudicators.—J. JULIAN.

### Croydon Horticultural.

A meeting was held in the society's room at the Sunflower Temperance Hotel, George Street, on Tuesday, October 7. By the kindness of the Croydon Public Libraries Committee and Mr. Jast, the chief librarian, a complete list of the magnificent volumes of the "Reichenbachia," a grand work on Orchids, and four volumes on "Choice Ferns," recently added to the library, were exhibited upon the tables. The chairman, Mr. W. J. Simpson, having called attention to the exhibits, introduced Mr. T. Neve, the Gardens, Lindesham House, Wokingham, who gave a practical lecture upon the "Renovation of Old Fruit Trees." In his introductory remarks the lecturer specially mentioned the value and importance of fruit as food, and the dietetic properties of Apples in particular. The lecture was illustrated by photographs of the trees mentioned, and by some excellent fruit gathered from them. Mr. Neve's lecture was much appreciated by all present. Several questions were put to the lecturer and ably answered, and a unanimous vote of thanks was accorded him. To the Libraries Committee a similar vote was also given. The subject for October 21 will be "How to Make an Alpine Garden" (from personal experience in the Alps and elsewhere), illustrated by diagrams, photographs, &c.

### Newport (Mon.) Gardeners.

The members of the above association held the first meeting of the session on Wednesday, October 8, when Mr. J. J. Graham, of the Cardiff Gardeners' Association, read a paper on "The Chrysanthemum." Mr. Graham is the holder of the challenge cup of the Newport Chrysanthemum Society, and his paper was looked forward to with great interest. There was a very good attendance, presided over by Mr. F. S. Daniels. Mr. Graham gave a very instructive account of the manner in which he treats his plants, commencing with the striking of the cuttings, potting on the plants, the soil, and the watering, which he considered of the utmost importance, being very careful not to overdo them with stimulants, and not to coddle the plants at any time. He then proceeded to give directions as to stopping the plants, timing and taking the buds, destruction of pests, housing, air giving, shading, &c., finishing his paper by remarking that all the trouble, care, and anxiety were forgotten in the glorious display made by the Queen of Autumn. A discussion followed, and many questions were asked by Messrs. Kenward, Daniels, Duff, Whitrow, Morgan, Pegler, Sharratt, Wiggins, and Neades. A splendid collection of upwards of thirty varieties of Apples and Pears were placed on the tables by that noted Monmouthshire fruit-grower and exhibitor, Mr. J. Basham, of Bassaleg, for which a certificate of merit was awarded. A Croton by Mr. Sharratt, and a Eucharis, by Mr. Lewis, were also shown.—J. P.

### Devon and Exeter Gardeners.

The annual meeting of the Devon and Exeter Gardeners' Association was held at the Guildhall on the 9th inst., under the chairmanship of the Mayor (Mr. A. E. Dunn). Those present were Messrs. W. B. Baker, Wm. Cobley, D. Betts, M. R. Court, J. Rogers, Wm. Charley, Wm. Andrews, E. Cole, W. Brewer, J. Hutchings, F. T. Baker, T. Cork, J. Isaac, T. Woodridge, E. Phillips, Wm. B. Chapbell, E. W. Miln, J. G. Anning, J. P. Rippon, C. Perkins, J. Langdon, R. Cripps, H. J. Baker, R. Mills, Andrew Hope (hon. secretary), and W. Mackay (treasurer). The hon. secretary read the committee's report, of which the following is a summary:—

Though the past year—the eleventh in the history of the association—has been of an uneventful character, it, nevertheless, has been one of steady progress and furtherance of the aims with which our work began. A noticeable feature in the meetings of the last session was the presence of young members as well as of many of the founders of the association, and the outspoken and friendly criticism upon the arguments and theories and methods advocated by those who prepared the papers read. By this means, undoubtedly, much practical benefit was bestowed, and the real interests of the society maintained and advanced. The practical side has never been overlooked or forgotten in the discussions. The continued kindness of His Worship the Mayor of Exeter in granting the use of so comfortable a room in the Guildhall for our meetings has been a great help, being so centrally situated, and has relieved the society from certain expenses or private obligations for accommodation which otherwise would have been incurred. A feature of our arrangements, introduced in the spring of 1901, was continued for the last two sessions, and added much to the interest and usefulness of the work done. That was the presenting of a nominal first, second, and third prize at each meeting for the best offered in competition by the members of such products as Beet, Leeks, Brussels Sprouts, table plants, Chrysanthemums, &c. These private competitions proved of great value as object lessons in teaching young gardeners what to aim at and what to avoid in specimens for the exhibition table. The committee, believing that much useful instruction was by this means indirectly conveyed to the members, have resolved to continue the scheme. As the voting is by ballot of the members present, an unbiassed and fair judgment is in every case given. Although the balance in the treasurer's hands is ample for all ordinary requirements, the amount has been reduced by the death of several kind friends of our association, such as Mr. Lethbridge, Mr. T. Snow, Mr. R. B. West, Mr. H. D. Thomas, and others, who were constant subscribers to our funds. If the state of our funds had warranted our doing so, the committee would have proposed to offer prizes to young gardeners for the best essay on some specific gardening subject, the award to be made by the committee. With gratitude and much pleasure the committee record the consent given by our very good friend Mr. E. A. Sanders to be again nominated as president of the association. Our thanks are also due to the local and horticultural Press for the excellent reports they have given of our proceedings. A series of papers for the autumn session is now being arranged, and it is hoped that they will prove no less interesting and instructive than those which have preceded them. Passing

reference may be made to the very pleasant summer outings held by the members in July last. By the kindness of Mr. T. B. Bolitho and Mr. R. F. Watkins, the charming seats of these gentlemen on the Dart were visited, and the rare trees and shrubs for which they are famous, inspected. A balance in hand was reported of £6 1s. 6d.

The Mayor, in proposing the adoption of the reports, thought they were, on the whole, very satisfactory. He was sure that every one of those members who had taken the trouble to attend the meetings regularly must have benefited by the different lectures. He thought their association was deserving of the greatest possible assistance.

Mr. R. Mills seconded, and the reports were unanimously adopted. Mr. A. Hope moved that Mr. E. A. Sanders be re-elected president. He was sure that if he had the whole of Exeter for a field to choose from, he could not find one more in touch with the association and with gardening.

Mr. W. Mackay, in seconding, said that during the time their association had been established they had had many presidents, but none who had done more good for the association than Mr. Sanders.

The re-election was unanimous, as was the re-election of the vice-presidents, viz.:—His Worship the Mayor of Exeter, the Sheriff, Major Tracey, Messrs. W. B. Heberden, C.B., C. T. K. Roberts, P. C. M. Veitch, R. G. Abraham, H. N. Imbert Terry, and G. D. Cann. Messrs. A. Hope and W. Mackay were re-elected secretary and treasurer respectively, and the committee were re-elected. A vote of thanks to the Mayor for the use of the Guildhall, and for his kindness in presiding, was heartily accorded on the motion of Mr. Andrew Hope.

### Beckenham Horticultural.

On Friday, October 10, the first lecture of the season, "The Watering of Plants," was delivered by Professor Percival, M.A., F.L.S., to an appreciative assembly; Dr. Randall, the chairman of the U.D.C., presiding. The lecturer referred to the mechanical action of watering, and counselled giving more care and thought than is usual. By the aid of diagrams, the root system was fully explained, the way in which water enters the plant by its root hairs, carrying with it nutriment, and was traced by the lecturer through the plant to the leaf, and the changes that take place there described. As a matter of fact, there are many side issues arising out of the watering question, much of this the lecturer dealt with in a most interesting and instructive manner, and at the close a most hearty vote of thanks was accorded to him. Mr. Price, of Broadclyst Gardens, had on view a collection of kitchen and dessert Apples, for which he was worthily awarded the society's certificate of merit.—T. C.

Apple, Lord Derby.

## APPLE, LORD DERBY.

One of the best culinary Apples, and largely grown, in use till Christmas, from the end of October. The fruits are large (as shown in our illustration) of excellent quality, and golden coloured when perfected; indeed, it is then a fruit fit for dessert. The trees bear well annually, and thus Lord Derby is much cultivated by marketmen. The habit of growth is upright. It is one of the best dozen Apples, and may be commended for general planting.

## Notes on Carnations.

The love for Carnations is ever increasing, and they seem destined to occupy as large a share of attention from the public generally as Chrysanthemums have for many years. A good deal of diversity of opinion exists as to whether autumn or spring planting is the better. My own experience has always been that one has to be guided by circumstances. In the South, West, and Midlands (except in cold districts) planting early in October answers admirably if the plants are well rooted, but when the layers are weak and not very well rooted, it is better to leave them undisturbed till March. Again, where the soil is very stiff, spring planting is preferable, so that after adding manure and burnt refuse in October, the soil may be thrown up roughly to become aerated during the winter.

In preparing the ground at the present time soils of light and medium texture should be dug deeply, and have a moderate dressing of well-decayed manure incorporated with them. If cow manure is used it should have lain in a heap for at least six months, and have been turned a few times. After the surface has dried, apply a heavy dressing of soot, fork it in, mixing it as thoroughly as possible with the soil. The heavy soil should be thrown up roughly, and if possible have plenty of burnt refuse, with a little lime scattered on the surface.

When collections are grown in the open I like to form beds, each having five rows, these to be 18in apart, the plants being set 1ft asunder. Then, with 2ft alleys between the beds, there is plenty of room to attend to cultural operations throughout the year. Plant carefully, sinking the stems up to the lower leaves, so that when the soil is pressed firmly around the stem each plant will be held securely in position. When this is completed run the hoe over the surface of the beds. Throughout the autumn and winter keep a sharp look-out for slugs. If they are found to be damaging the plants, catch as many as possible, and dress the bed frequently with air-slaked lime.

In spring, birds often do much damage by eating the leaves, and unless measures are taken to stop them they quickly ruin hosts of plants. Webbing the bed thickly with black cotton and hanging a few cheap mirrors (which may be bought for a few pence) from strong stakes by means of string, are effectual ways of scaring the feathered tribe.

The following varieties all produce large, handsome flowers, and have a robust habit of growth: Aline Newman, deep red; Artemus, scarlet; flaked and streaked lavender; Boadicea, rosy scarlet; Bomba, salmon pink; Brodick, yellow, flaked and marked with red; Dervish, yellow, margined lilac rose; Duc d'Orleans, yellow and buff, very large; Garville Gem, heliotrope; H. Falkland, yellow, edged with bright rose; La Villette, pink and yellow; Mephisto, a grand crimson; Mrs. Eric Hambro, white; Mrs. J. Douglas, rose; Mr. Nigel, yellow-crimson edge; Queen of Scots, rose-pink; Silver Strand, a grand white; The Hunter, an improved Mrs. Reynolds Hole; Voltaire, yellow ground, edged and marked with rose; Sir Waldie Griffiths, crimson; and Waterwitch, blush-white.—DEVOTEE.

## Trade Catalogues Received.

Frank Cant & Co., Braiswick Rose Gardens, Colchester.—*Roses.*

J. Cheal and Sons, Lowfield Nurseries, Crawley, Sussex.—*Trees and Shrubs, Fruits, Roses, &c.*

E. P. Dixon & Sons, The Nurseries, Hull.—*Fruit Trees, Roses, &c.*

F. C. Heinemann, Erfurt, Germany.—*Special Trade Offer of Novelties.*

Thomas Rivers and Son, Sawbridgeworth, Herts.—*Fruit, Trees, Roses, &c.*

Will Tayler, Osborn Nursery, Hampton, Middlesex.—*1, Select Fruits; 2, Roses.*

D. S. Thomson & Sons, The Nurseries, Wimbledon.—*Roses, Fruit Trees, Shrubs, Plants.*

## Hardy Fruit Garden.

**PEACHES AND NECTARINES.**—Give all possible assistance to trees ripening their fruit. The clearance of any superfluous shoots permits access of light, while leaves obstructing sunshine and shading the fruits may be drawn on one side or cut in two. Hang nets in front of the trees to prevent injury to the fruit from birds. The nets may be tied under each fruit so as to form small pockets, which will catch the fruits should they prematurely fall. To obtain the highest flavour and quality in good fruit gather them before being quite ripe, and finish in the fruit room. When the trees have been cleared of fruit a re-arrangement of growths may be made, as the old bearing growths can be cut out, and possibly some rather weak or semi-exhausted branches may need removal. After the principal branches have been regulated the current year's young shoots may be laid in between them. Should red spider be present at all, previously give the trees a thorough cleansing with the garden engine, though if the attack is unusually bad an insecticide is necessary. The true cause, however, of such severe attacks of this pest will be found to be a dry border. Hence, give a thorough soaking with clear water. Afterwards a little weak liquid manure should prove beneficial.

**MORELLO CHERRIES.**—The crops, even from late reserved trees, will now be gathered. It is, therefore, desirable to examine specimens on walls or trellises in order to discard any exhausted or worn out growths, and to remove the old bearing shoots, relaying the current season's growths by which they may become thoroughly well ripened. Young trees which have had a certain amount of freedom of growth must now have it regulated and equalised, so as to produce a well balanced specimen. Any trees growing too luxuriantly ought to have a gentle check by judicious root-pruning or lifting and replanting. Red spider frequently attacks Cherries on walls. Should there be any present on the foliage it is desirable to destroy it. Vigorous syringing, either with or without insecticide, effects this. The chief cause of insect attacks of this character is dryness at the roots. To avoid trees suffering from their destructive influences keep the border moist, roots plentiful and fibrous, affording a mulching in summer to encourage surface rooting and prevent rapid evaporation.

**OUTDOOR FIGS.**—Lay in strong healthy growths at regular distances apart, or so as to furnish the trees equally. Small and useless spray may be cleared out entirely. Well ripened growths are the most productive in fruiting.

**OUTDOOR PEACH AND NECTARINE TREES.**—The whole of the growths which have borne the present season's crop may be cut out, their place being taken by the reserved growths of the current season. These, if too numerous, may be thinned, for it is useless to retain a number of growths for which, however suitable they may be for bearing, no room can be found without unduly crowding. Exhausted growths or branches, too, may be removed; in fact, nearly the whole of the pruning may be carried out, though no shortening of young wood should be effected now. After this, the trees will probably need re-arranging, for which purpose it may be essential to loosen them entirely from the wall or trellis, so as to better distribute the branches. The main object now, is not so much to make the trees perfect examples of training, as to ripen the wood thoroughly, and to this end the autumn pruning must be mainly directed, leaving the final training until spring, when a little more pruning will be essential. The soil about the roots also must be examined, giving a copious soaking where the roots are found to be ramifying in very dry material. It is not too late to lift and replant any trees which are found to be growing too strongly, and which are, or likely to be, fruitless in consequence. Of course, young and portable trees can only be dealt with. In common with other wall trees, Peach and Nectarine trees may also be planted. Prepare the soil by liberally digging. Rather than add manure, introduce some fresh soil, which should be of a calcareous character. Soils deficient in lime should be improved by its addition, also wood ashes. The dwarf fan-trained are the best for ordinary sized walls. Plant firmly, but only loosely secure the branches to the wall or trellis, so as to permit of the soil and the trees settling down together.

**GENERAL HINTS ON FRUIT TREE PLANTING.**—The season has practically arrived when a commencement may be made in the important work of planting fruit trees and bushes. Although the leaves may not yet have all fallen, they are in such an advanced stage of ripeness that their presence need be no drawback to planting Gooseberries or Currants during the present month; also stone fruit trees desired to be established against walls or trellises. The planting of small bush fruit generally admits of the ground being liberally treated in the matter of digging and

manuring, but for stone fruits, also Apples and Pears, the soil must be well broken up and pulverised without manure as a rule. The order for fruit trees and bushes should be placed with good and reliable nurserymen, who make a speciality of supplying the best varieties true to name. The bulk of the varieties chosen should be such as do well in the neighbourhood, including some which are promising in every way, but not usually grown in the district. On receiving fruit trees from the nurserymen, it is very important that they be carefully unpacked, and laid in the soil at once, so as to preserve the roots from drying until proper planting can be carried out. Prior to planting, the roots must be carefully examined. Any of those injured must be cut back to healthy parts. In planting, spread out the roots in wide and shallow holes. Cover them with a good mixture of fine soil worked firmly about them. Stake standard trees immediately, and mulch round the roots of all with flaky manure.

**AUTUMN FEEDING OF THE TREES.**—Much may be done to improve fruit trees which are in a fruitless condition owing to impoverishment of the soil from a deficiency of food and moisture. Such trees make but small quantities of new wood annually, and the fruit buds suffer from their lack of energy. Wall trees often experience these conditions from various causes. Their position is naturally drier, and the soil more freely drained. The borders containing the roots are frequently cropped with vegetables and other crops, which abstract both food and moisture. Clear away surface crops and weeds, at the same time loosening the soil. Follow by applying a copious soaking of water, enough to moisten the soil to the lowest roots. Having thus secured moisture in the soil, a similar application of strong liquid manure may be given, so as to reach the whole mass of roots. The roots of wall trees will extend at various distances from the front, but the chief or fibrous roots ramify within a few feet. Old established standard trees, with large spreading heads, will have roots extending the same distance in the soil. The moistening and feeding must reach the extremities of these to effect good results. Trees on grass are moistened by making holes with a crowbar over the rooting area at short distances apart. These holes may be repeatedly filled with water and liquid manure, until the soil is sufficiently moistened and fertilised.

### Fruit Forcing.

**VINES: EARLIEST FORCED IN POTS.**—To produce ripe fruits in late April or early in May the Vines are best grown in pots, as stated in a former calendar, selecting early sorts, such as White Frontignan, Buckland Sweetwater, and Foster's Seedling in white Grapes, and in black Royal Ascot, Black Hamburgh, and Madresfield Court. They should now be placed in position preparatory to starting them early in next month.

**EARLIEST FORCED HOUSE.**—Where late Grapes are not cultivated extensively to maintain a supply to May, or thin-skinned Grapes are required by April, preparations must be made for early forcing. The Vines having been pruned in September, the loose bark stripped off, the house may be cleaned, the border top-dressed, and the Vines treated with a solution of paraffin emulsion, 8oz to a gallon of hot soft water, adding  $\frac{1}{2}$ oz sulphide of potassium or liver of sulphur, thus combining an insecticide with a fungicide, effective against Vine pests, mildew, and other fungoid affections, red spider, thrips, scale, and mealy bug. To have Grapes ripe in April the house must be started next month, as under favourable conditions five months are required to produce ripe Grapes of even the early varieties during the duller period of the year. It can be done in much less time on the express forcing system, but the strain on the Vines is so great that they are little good afterwards.

**MIDSEASON HOUSES.**—When the leaves are all down the Vines should be pruned, any Grapes remaining be cut with enough stem for inserting in bottles of water and placing in a cool, rather dry room, where they will keep better than on the Vines. This will allow of the house being thoroughly cleaned, also the Vines, upon which much of success or otherwise depends in the coming season. It is better to do this than to leave the house and Vines in a dirty condition until a convenient time, which usually is badly performed later from the press of other matters, and the pests have time to hibernate in retreats where they cannot be reached by insecticides. Where Grapes are hanging air will need to be admitted on all favourable occasions, and a gentle warmth be maintained in the hot-water pipes, so as to promote a circulation of air in dull, damp weather and prevent the deposition of moisture upon the berries. Bad leaves must be removed, and the Grapes seen to occasionally for the removal of decayed berries.

**LATE GRAPES.**—There is little difficulty in keeping such thick-skinned Grapes as Alicante, West's St. Peter's, Gros Guillaume, Gros Colman, Mrs. Pince, Alnwick Seedling, and Lady Downe's, provided the roof be waterproof, drip avoided, and moisture prevented from deposition on the berries, which can be done by judicious ventilation and gentle warmth in the hot-water pipes. White Grapes, however, except Calabrian Raisin, which has a tough skin, do not keep nearly so well, both Syrian and Trebbiano being in a degree only less liable to spot than Muscat of Alexandria, which, when finished so as to hang in good condi-

tion till January, is supreme among Grapes. Its great enemy is spot, and that of two kinds—one caused by moisture on the berries, and the other by a fungus, which cannot attack the berries successfully until their epidermises are suffused with moisture in a stagnant state—that is, resting (though imperceptible) on them. The means, therefore, of avoiding both is to prevent the atmosphere becoming stagnant, a temperature of about 50deg being necessary, and air must be given early on fine mornings, with warmth in the hot-water pipes to expel moisture and allow of the berries being warmed equally with the surrounding air, moisture being kept from condensing on the berries. There must not be anything like a leak in the roof, no mouldy leaves or decayed berries, and moisture kept down as much as possible, that likely to arise from the border being prevented by covering it with dry material, than which nothing answers better than roughly cut, clean, sweet, and dry Wheat straw.

### Meteorological Observations at Chiswick.

Taken in the Royal Horticultural Society's Gardens at Chiswick, height above sea level 24 feet.

The first part of the week was dull and dry, the latter part brighter, but more unsettled, with rain on three days.

### Publications Received.

"Journal of the Department of Agriculture of Victoria," August, 1902. Part 8 of vol. 1. Chief contents: Phylloxera-Resisting Stocks, Poultry and Their Diseases, Fruit Preservation, Vegetation Diseases Act, Rust in Wheat, and Black Spot of Apple. \* \* "Le Jardin," September 20. Contains: Culture of Saintpaulia ionantha, Terrestrial Orchids, A New Transplanting Machine (Illustrated), &c. \* \* "An Afrikaner's Appeal to Afrikaners to Assist in Bringing About Peace in South Africa," by H. W. Fourie, jun.; Cape Town: Office of "De Kolonist," Brie Street. (Sent by Peter Barr.) \* \* "Garten Flora," September 15. \* \* "The Canadian Horticulturist," September, 1902. Special features: Bradshaw Plum, Plum Growing in Ontario, Popularising Public Parks, Burlington Fruit Station, The Yellow Day-Lily. \* \* "Men of the Moment," No. 5, the Right Hon. A. J. Balfour; Treherne's Penny Series. \* \* "Le Moniteur d'Horticulture," September 10, contains a coloured plate of hardy Philoxes (six varieties). \* \* "The Western New York Horticultural Society." \* \* "Meehan's Monthly," September, containing an elegant coloured plate of Monotropa uniflora. \* \* "Third Annual Report on the Soils of Dorset," issued by the University College, Reading, August 1902, price one shilling. \* \* "Le Jardin," September 5, coloured plate of three Gentians and three Primulas. \* \* "Cassell's Dictionary of Gardening," part 17, price 7d. net, contains a coloured plate of Sutton's Blue Primula, and many beautiful illustrations. The part ends at Siegesbeckia. \* \* Autumn syllabus of Swanley Horticultural College; also syllabus of work done in summer 1901. \* \* "Miniature Rifle Clubs, and How to Form and Conduct Them," by H. Marks; London: 17, Victoria Street, S.W. \* \* "The Chemistry of the Farm," by R. Warrington; London: Vinton and Co. (Limited), 2s. 6d., new edition. \* \* "The Tropical Agriculturist," September; this number contains notes and articles on the following subjects: Fish Culture in Ceylon, Rubber Planting in the Malayan Peninsula and British North Borneo, Vanilla Cultivation in Seychelles and Ceylon, Tea Growing at a High Elevation in Ceylon, Trees for Tea Estates, Troubles of Cocoa-nut Planters in the Straits, Fever in Plants, Flora of Malay Peninsula, A New Pepper, and Wood Fuel. \* \* "Garten Flora," October 1, contains a coloured plate of Cyrtopodium punctatum, Lindl. \* \* "Bulletin de la Société Centrale d'Horticulture du Département de la Seine-Inférieure." \* \* "Le Moniteur d'Horticulture," October 10, with coloured plate of Roses, the varieties being G. Nabonnand and Princess de Bassaraba de Bracovan, both Teas.

\* \* All correspondence relating to editorial matters should be directed to "THE EDITOR," 12, Mitre Court Chambers, Fleet Street, London, E.C. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense.

**BOOKS WANTED (J. B.).**—We do not publish the book you name. (A. B.) Apply to Wesley and Son, Essex Street, Strand, London.

**PHOTOGRAPH OF GOOSEBERRY.**—Would "W. B." Buffham, Lincoln, who sent photograph of a Gooseberry, kindly send his full name and address to the Editor?

**JOINING THE ROYAL HORTICULTURAL SOCIETY** (Thos. Bell).—Write to the Secretary, Royal Horticultural Society, 117, Victoria Street, Westminster, London, S.W.

**TOMATOES WITH A MOTTLED APPEARANCE** (Tomato).—The fruits have parts here and there of a waxlike consistency, remaining of a firm texture and of an unripe colour, while the remainder of the individual fruit is quite soft, thoroughly ripened and good in colour of skin, giving a mottled and badly perfected appearance. Various opinions have been given as to the cause, but not any satisfactory explanation of the phenomenon based upon chemical research. It unquestionably arises from a deficiency of potash in the fruit for the transmission and diffusion of the juices; at least, a due supply of that element to the plant has proved of great advantage in preventing the defect. The potash is best supplied in sulphate form, and mixed with the soil, 2oz or 3oz being applied per square yard, some time in advance of planting, pointing in lightly, and again stirring at planting time about 6in deep. It is also noteworthy that phosphate of potash has a similar effect, the plants, especially those grown in pots, being watered after the first trusses of fruits are set with a solution at the rate of  $\frac{1}{2}$ oz to 1oz per gallon of water. It has a very marked effect on the cropping of the plants and the perfecting of the fruits. The phosphate of potash, however, is very dear, some £20 per ton, hence, practically precluded as an article in profitable cultivation. The sulphate acts well, but it is advisable to use it along with superphosphate, say three parts superphosphate and two parts sulphate of potash, applying 4oz of the mixture per square yard, and repeating after the fruit is fairly set in about half the amount at intervals of three weeks once or twice.

**VINES UNHEALTHY (A. B.).**—The specimens that were sent to us before clearly did not represent anything like the actual condition of the Vines, and we are sorry to have been misled by them. Even if you have sent the very best examples obtainable, and taking the others as the worst that could be found, the average condition of the Vines is very much better than we were led to infer from the data supplied. Your letter is much more intelligible than the other we received, and it indicates that you have a good general knowledge of Vine culture. You proceeded cautiously and wisely in the work of renovation. It is quite natural that your employer would not like being without Grapes for a year, and you did the best you could to provide some; and now we understand the case we do not suppose the crop would do any material harm. It is always advisable to allow Vines, as far as possible, to start into growth naturally after much disturbance of the roots, even if extra heat has to be provided afterwards, when new roots are working in the soil, to get the crops and wood ripe by the autumn. You are working at a disadvantage in a high cold dull district; the very large leaves you have sent show this clearly enough. They have not had sufficient sun to elaborate the crude sap—hence their enlargement and the softness of the tissue. The less the light the larger the leaf. Under such circumstances firm borders containing much calcareous and other gritty matter should be provided, and loose rich borders avoided. A multiplicity of surface roots should be the great object, as these are followed by sturdy growth and stout leaves; and whatever extra support may be required for the crops can be applied from the surface. It is also very important that the Vines and laterals be thinly trained. Not a leaf should be permitted to form that cannot develop under the direct action of light. There must not be the slightest suspicion of overcrowding, while all the air possible must be admitted consistently with avoiding sharp currents, even if a little extra fire heat has to be employed to maintain the requisite temperature. Where there are frequent changes of gardeners there are, as a rule, unsatisfactory Vines. We are convinced the Vines referred to will improve under your management, as your past experience with them will be turned to account in a manner adapted to their peculiar condition; a

stranger would have all this to learn, and in the meantime it would be a mere matter of chance if the Vines did not suffer. That is the reason that Grapes are rarely satisfactory when many different persons share in their management.

**NAMES OF FRUITS.**—Correspondents whose queries are unanswered in the present issue are respectfully requested to consult the following number. (T. R. B.).—1, Jefferson; 2, Bramley's Seedling. A number of replies have to remain unanswered till next week.

**NAMES OF PLANTS.**—Correspondents whose queries are unanswered in the present issue are respectfully requested to consult the following number. (Zoe).—1, Begonia (see next issue); 2, Begonia semperflorens var.; 3, Begonia fuchsoides; 4, Begonia semperflorens var.; 5, Adiantum Moorei; 6, Adiantum gracillimum; 7, Cypripedium barbatum superbum; 8, Cypripedium pardinum. (Prestonkirk).—No. 6, Mesembryanthemum crystallinum; the fruits will be named in another paragraph. (A. B.).—1, Ilex Aquifolium aureo medio-picta; 2, Ilex dipyreana; 3, Ilex Aquifolium camelliæfolia. (L.).—Calceolaria integrifolia. (C. A. W.).—1, Tradescantia virginiana var.; 2, Aster Novæ-Angliæ var., probably præcox; 3, Aster vimineus var.; 4, Helenium autumnale; 5, Galega officinalis; 6, Rudbeckia fulgida.

## The Breeding of Cows.

Out with a party shooting the other day, our equanimity was rather disturbed by the very wild and threatening appearance of a young bull, which appeared to resent our appearance in his private domain. He was not handsome, and if he had been the right colour would have reminded us forcibly of the bull in Paul Potter's famous picture. His plain, cross bred appearance, and painful want of flesh, prompted an inquiry of a labourer as to his breeding and pedigree. He was bred on the farm, and his dam had been the best cow in the neighbourhood for milk and butter, which was the reason for his entire condition. This farmer was using this bull in the attempt to breed some good milkers, and we think he was adopting a sensible course. There is no doubt that the average farm dairy cow is capable of enormous improvement, and as the supply of cows needs much replenishing, in trying to increase the stock we should also try to raise the standard of quality, not with a view to the butcher, but with a view to milk production. The increase in the price of meat may induce farmers to breed fleshy animals; but the demand for good milk cows is a staple one, whereas meat may, and probably will, return to the old 6d. per lb price before next year's calves can be reared and fit for the butcher.

On many large dairy farms (and we speak what we know) the average produce of each cow per day is little more than two gallons of milk. As we often meet with individual cows which will give five gallons per day for months (we once owned a cow which would give seven and a half gallons for some weeks after calving), there seems to be a wide field for improvement. Dairy farmers are often grumbling that they cannot get adequate prices for their milk; that 8d. per gallon the year round does not pay them, and so on. There is little prospect of their obtaining more than that, on an average of several years, and if two gallons per day at 8d., or 9s. 4d. per week, does not pay for the cow's board and lodging, she must be superseded by one which will make a better return.

The multiplication of shows where all the prizes are given for what are practically butchers' beasts has improved the herds of the country in that direction, but at the expense of milking qualities. Efforts have been made to counteract this, and there are now shows where the object is to encourage dairy stock, and at some of the older shows there are now classes for milk cows as such; that is, for the best milkers, on the principle that handsome is that handsome does.

Being short of cattle, we shall have to breed freely, and from such cows as we have; breeding from only the best would mean not breeding enough. We must therefore, perforce, breed from many poor milkers; but we have the power to improve them, and that is by mating them with a bull from a crack cow. An increase of four pints of milk per day, at 8d. per gallon, would, on fifty cows, mean a profit (if there were none before) of more than £300 per annum. Much has been done to improve our breeds of live stock, but too much attention has been given to appearance.

The "John Bull," so familiar as a type of our race, is an example of the flesh producer; but we do not find go-ahead nations like the Yankees paying sole attention to one article of commerce, and we must, like them, put aside sentiment and the worship of appearance in the show yard, and breed that which does most for the balance sheet. A cow which can give six gallons or upwards per day should never be slaughtered so long as she is capable of bearing a calf; but we are sorry to have to say that too often such animals are sold to town dairymen, who give a big price for them, but who make very perfunctory attempts to breed from them.

They milk them so long as they will pay for expensive town keep, and then sell them to the butcher.

A farmer who has an eye to his own profit should never let such a cow leave his premises, however tempting the price, until his farm is so well stocked with similar animals that a draft sale becomes a necessity. Would Mr. Evens, of Burton, Lincoln, have built up such a milking herd as he now possesses if he had sold all his best cows to the first customer? No! It is only by selecting and keeping the best, using the most suitable sires, and refusing to town dairymen the cows which as a duty we should keep for breeding, that we can make permanent improvement in the milking averages of our dairy cattle.

A word about the "Jersey." A cross of this breed is good to keep up, or, rather, bring up, the average of butter-fat to a high standard; but though the Jersey is a good butter cow, it is but a moderate milker. It is "par excellence" the rich man's cow, but is not the "rent payer." For milking qualities an Ayrshire cow, though she be but small, takes much beating; and an infusion of Ayrshire blood will be good for the milk average without affecting the quality. Some of the best milkers we have seen have been cross bred Irish, whose pedigrees were untraceable. Possibly they were Kerry-Dexter, with a cross or two of Shorthorn; but, at any rate, they were marvellous milk producers. We once bought such a cow, apparently barren, for £10, with the intention of feeding her. She turned out to be in calf, and, after calving, gave eight gallons of milk per day for several days, until we sold her for £20 without her calf. We milked her three times a day, as she had a habit of milking herself, which was perhaps the reason why she was sold to us. For national economical purposes such a cow should have been kept for breeding at the public expense.

## Work on the Home Farm.

Of work during the past week there is little to record, for little has been done except ploughing for Wheat. We have been trying to thresh, but the north-easterly drizzle has been so persistent that a day's work has occupied three days, and the sample is hardly in saleable condition. Potatoes are waiting to be picked up, and the Irish labourers are waiting very patiently for the chance to pick them. They began work to-day, but both Potatoes and pickers got wet. We find that prices for picking vary greatly. Maerekers and Scotch Dates are 3s. or 4s. per acre more costly than the others, which is an excellent testimonial to their worth. We prefer Scotch seed of "Up-to-Date" Potato. The Professor is free from disease, but is not good enough in quality.

Notwithstanding the scarcity of labour, the spinning Potato digger finds little favour. There is a strong idea fostered by Potato dealers that these machines greatly damage the tubers. Well, reapers often greatly damage the corn, but nevertheless farmers do not discard their use. A farmer who uses a digger with fair intelligence will never again wish to use a plough; but to make a digger a success there must be no ridges thirty or more inches in width.

The corn market reports make sad reading. We were prepared for lower prices, but not for the absolute panic caused by the glut of ill-conditioned samples. The wet weather may do good in delaying threshing, and so keeping the market comparatively empty. The threshing machine shows that a large proportion of this season's corn was badly got, and farmers who must thresh, should choose their driest stacks to begin with. Barley is also coming out in very poor condition, as well as variable in quality. It is most necessary that Barley should be shot into a heap in the granary. The heap should be well turned and dressed before a sample is taken, so that the bulk and sample may correspond. With improvements in threshing machines which now make very finished samples, there is a tendency to save money and labour by weighing sacks directly from the machine, but though the latter may dress well, it does not mix the whole into equality. That must, and can only be done on the granary floor. Factors soon know perfectly well which men sell direct from the machine, and which shoot their grain and make a proper sample, and they bid accordingly.

It has been too cold and wet for the calves to remain out, and they will be kept up altogether. Feeding cattle are barely holding their own on the pastures, though they are consuming heavily of cotton cake. They will be better in the covered yard eating the excellent white Turnips which we can provide for them. The grass they leave behind will be useful for the ewes later on.

The weather having interfered with other work, we have been able to clean out a few ditches and watercourses. Though there is little to show for this work at the time, it is still most necessary, and no time is better than the present, for with the approach of winter watercourses will become flushed, and far more difficult to deal with.

THURSDAY, OCTOBER 23, 1902.

**Provident Gardeners.**

ONE who has most minutely chronicled the history of English horticulture down to his own era, a full generation ago, records the existence in the England of one hundred years ago, a mutual benefit society of gardeners. "Adam's Lodge" was founded in London on the 4th of June, 1781, as "a fraternity of gardeners to establish a fund for the mutual support and relief of each other in time of sickness, lameness, or distress;" and the illustrious Loudon, who preserved so much that was valuable by his writings, adds that in 1824 "the Lodge" consisted of 150 members. From lack of monetary support in proportion to the demands upon its treasury, this earliest gardening benefit society slowly drooped, and finally passed away.

Thirty-six years ago, however, another institution, having exactly the same purpose and aim, was originated at the Green Dragon Hotel, Bishopsgate Street, in the City of London, and the United Horticultural Benefit and Provident Society is to-day swelling its sphere of useful operation to every parish throughout these teeming Isles. As we write a statement of the work and privileges of this society, prepared by its treasurer, Mr. James Hudson, V.M.H., comes to us, and the facts herein stated we are pleased to publish. Mr. Hudson says of the society:—"Like many other such institutions, its progress at first was slow. Thanks, however, to its friends and supporters, its merits were realised by some of those for whom it had been constituted, and for the past sixteen years there has been an uninterrupted run of prosperity. Twenty-one years ago, in 1881, the membership was only eighty-eight; in 1886 it was 177; in 1891 the number was 413;

READERS are requested to send notices of Gardening Appointments or Notes of Horticultural Interest, intimations of Meetings, Queries, and all Articles for Publication, officially to "THE EDITOR," at 12, Mitre Court Chambers, Fleet Street, London, E.C., and to no other person and to no other address.

and in 1896, 639. At the last audit the numbers were 904 (end of 1901), but now there are 974 benefit members. The executive hope that the number at the close of this, the Coronation year, will amount to 1,000. The funds of the society have increased in a similar ratio. These in 1901 stood at £6,822; at the close of the last financial year, the amount invested and in hand for current expenses were £19,086. At the present time they stand at £20,000 in the aggregate.

"Some of the large benefit societies have heaped up their funds in tens of thousands by the misfortunes of their lapsed members, yet have not so large an average sum per member. In these societies members who allow their subscriptions to lapse lose everything.

#### "The Benefit Fund.

"It is entirely opposed to all reason that in a 'benefit' society any section of the members should profit by the misfortunes of others. It cannot possibly occur in our society. The 'United,' from its commencement, has credited to each member his proportion of the year's working. Thus, some have now to their credit in the books of the society over £100, to which is added yearly 3 per cent. interest. Each member has to contribute his proportion towards the Sick Fund of the current year, after which the balance is placed to his own account. A yearly balance-sheet is issued to each member, so that he knows from year to year exactly what funds he has to his credit. And in the event of his decease, his nominee can know at a glance what that balance is. When a member reaches the age of seventy years he can withdraw his balance in one sum, or in smaller amounts. Lapsed members, i.e., members whose accounts have been closed through ceasing to pay their contributions, can obtain their balances upon attaining the age of sixty years, the sum paid to such being the amount standing to their credit when they became lapsed members.

#### "The Benevolent Fund

is provided for by the contributions of life and honorary members, and by a small annual sum from each benefit member. This fund provides for all members after they have passed the age of seventy years. It also assists members in cases of accident or other peculiar forms of distress, and the widows of such members who die in needy circumstances. The committee appeal urgently for more honorary and life members so that this fund may be increased in proportion to the number of members. With one thousand benefit members, the number of honorary and life members should be at least one hundred.

#### "The Convalescent Fund

is a purely voluntary one on the part of the benefit members. It was instituted through the kindness, liberality, and business forethought of Mr. N. N. Sherwood. Its funds are devoted to assisting members by a grant, so that they can obtain a change of air during convalescence. In the case of young gardeners who may be in lodgings during sickness, it is an important aid to their recovery.

#### "The Management Fund

is directed to the working expenses of the society. During 1901, with 904 benefit members, it amounted to £163 14s. 10d., an average of about 3s. 7d. per member, towards which each member contributes annually the sum of 2s. 6d.; the balance being made up from the interest of monies standing to the credit of the lapsed members, and by the proceeds from advertisements in the annual report.

"The committee considers that this society in a measure fulfils what has been often urged upon the community at large, viz., the provision of 'old-age pensions.' It is a self-help society, its rules being framed so that the utmost possible return may be made to every member belonging to it, and in proportion to the number of years each one has contributed. The secretary is always willing to supply any information as to scales of contribution, &c. The funds are invested in approved trustees' stocks, which yield on an average about 3 per cent."

## Quinine and Its Romantic History.

Many of the greatest benefactors to mankind have been discovered through the merest of accidents, of which saccharin may be cited as a case in point, but we doubt if there is any other drug which has a more romantic history than quinine, which may really be said to be now a household medicine, as well as a household word.

Although Peruvian Bark was used in England as early as 1655, and was advertised in 1658 as "the excellent powder called by the name of Jesuits' Powder, brought over by James Thomson, merchant, of Antwerp," it was not until 1677 that the drug was included in the British Pharmacopœia. What is now, however, known as quinine was not discovered till 1811, and it was not obtained in a pure state by complete separation from the other constituents of the bark till some ten years afterwards.

Put into unscientific language, quinine may be described as the base, or essential principle, of the bark of certain individuals among the Cinchona family of trees, the result being one of the most important of the alkaloids. This bark was first introduced into Europe in 1632, although it is generally said to have been unknown there before the return to the City of Madrid by the Countess of Cinchon, the wife of the Viceroy of Peru in 1640. This lady, from whom the bark-producing trees derive their botanical name, had been cured by it of a fever contracted in Lima in 1638, but the Jesuits who had settled in Peru were fully alive to its virtues long before, and as those missionaries were the general agents for its distribution in Europe, it came to be known as "Jesuits' Powder," while in Madrid it was called "Countess' Powder," and in Rome as "Pulvis Patrum."

In the cities of Brussels and Antwerp it was sold for its weight in silver, which was then about ten times the price of opium, and in 1658 twenty doses were sent from Rome to Paris at an expense of sixty florins. Louis XIV. used it for a dangerous illness, and our own Charles II. had also had it administered to him. The bark was looked upon as almost a miraculous cure for fevers and agues right down to the end of the seventeenth century. Humboldt raised doubts as to whether the curative nature of the bark was originally known to the Peruvians, but in the light of later information there can be little doubt the natives did know.

The tradition is that the properties of the bark were first practically realised by a fever-stricken Indian, who, being left behind by his companions as is their wont if sickness overtakes one of their number, drank of the stream which flowed through the forest wherein he was stricken, and which had become impregnated by the bark of the overhanging Cinchona trees. His cure was so rapid that on his return to his tribe his restoration to health was looked upon as miraculous, with the result that the Indians flocked to the stream to partake of its wonderful water. The Cinchona trees were chiefly to be found upon the Eastern slopes of the Andes, and until the discovery of quinine the Peruvian bark of commerce was drawn in the main from this district, the finest quality, grown in the town of Loxa, and known as Crown Bark, being long reserved for the Royal Family of Spain.

Of course, the demands of Europe soon denuded the native forests of their trees, and led to the cultivation of the Cinchona in other districts. The Dutch were the first to make the experiment of cultivating the plant in Java, where they met with much success, their example being followed by the Indian Government and by English residents in the East, with the result that for many years past there have been extensive plantations in the Neilgherry Hills, British Sikkim, Bombay, and British Burmah, while the growers of Ceylon have extensively planted it in Colombo. Some fifteen years or so ago there were only seventeen known factories of quinine in existence—being six in Germany, four in America, three in France, two in Italy, and two in England—the total consumption then amounting to 4,250,000 ounces, which must, however, have been since largely increased through the epidemics of influenza and other causes. Thus during the cutting of the unfortunate Panama Canal some 200,000 ounces of quinine were distributed every year among the labourers to counteract the malarial fever of the Isthmus. Madame de Genlis founded a novel on quinine, and Lamartine indited a poem in its praise, and, all round, the drug possesses a decidedly romantic history.—WM. NORMAN BROWN.

### *Lælio-Cattleya* × *Cooksoniæ*.

The parentage of this hybrid was *Cattleya labiata* and *L.-c.* × *Clive* and it is a handsome and massive flower. The sepals are rosy lilac and the petals the same. The rich velvety lip is bright purple or crimson-purple, deepening towards the contortuous, indented marginal parts. The flower seen at the Royal Horticultural Society's meeting in the Drill Hall, James Street, Westminster, on September 3, was strong and substantial in its composition, denoting careful culture. Norman C. Cookson, Esq. (gardener, Mr. H. J. Chapman), Oakwood, Wylam-on-Tyne, was the exhibitor, and was accorded a First Class Certificate. Our illustration is from a drawing by Mr. Geo. Shayler.

### **Dendrobiums: Their Growth and Culture.**

(Concluded from page 351.)

*D. Parishii* is a Moulmein species, sent home by the late Rev. C. Parish, whose name it commemorates. It is an ugly grower, but produces very pretty rose-purple blossoms, and thrives with the deciduous section.

*D. Phalaenopsis* is the finest of the Australian group, and almost as freely distributed as *D. nobile*. Numberless varieties of this superb species exist, the colour varying from pure white to the deepest crimson purple. *D. Pierardi* is a cheap but very effective species, producing an immense number of its pale rosy-mauve blossoms in spring. In large baskets the pendant stems have a delightful effect, especially when backed up by green Palms or Ferns, as when in flower it is destitute of foliage. It is a very widely distributed plant, naturally growing wild in Moulmein, India, and the Sikkim Himalayas. *D. primulinum* has stout stems and pale mauve flowers, and is worthy a place among the deciduous species.

*D. speciosum* is a large growing evergreen plant, producing large dense racemes of white flowers with a creamy suffusion and purple spots. To flower it successfully, it should have a few weeks in the open air in autumn after the growths are made up, and be kept well on the dry side in winter. Its variety *Baneroftianum* is smaller, but bears more graceful flowers. The variety *Hilli* is taller in growth than the type and bears paler tinted flowers.

*D. superbicus* is a showy species from the islands about the Torres Straits, bearing terminal and side racemes of bright crimson-purple flowers in the autumn, and requiring similar treatment to *D. Phalaenopsis*. *D. superbum* is a long stemmed deciduous species, very variable in colouring, the type having magenta purple flowers. It is a native of the Philippines. *D. taurinum*, *D. stratiotes*, and *D. strebloceras* form almost a distinct section of the genus, the peculiar twisted segments being different from anything else in it. These plants are difficult to establish and grow, and never attain anything approaching their full size in this country.

*D. thyrsoflorum* is one of the finest of the evergreen sort, producing lovely racemes of milk-white flowers, with a bright yellow lip. Fine well-flowered specimens of this noble Orchid are splendid for conservatory decoration or for display in the flowering house. It is one of the best known, having been introduced from Moulmein in 1864 by Messrs. Hugh Low and Co. *D. tortile* is a little like *D. nobile*, pale rose in colour on the outer segments, the lip yellowish, with a purple blotch. It flowers in June.

*D. Wardianum* is a well known and beautiful sort, without which no collection is complete. The flowers have ivory-white sepals and petals, tipped with magenta, the lip having a yellow area about the base, with two eyes like blotches of maroon. The varieties differ a good deal in size and substance, but I have never seen a form that is not worth growing. It succeeds with the other deciduous species. So far I have not mentioned any of the hybrids now so plentiful in this genus, but as this note is already overlong, I hope, with the Editor's permission, to touch on these briefly on a future occasion.—H. R. R.

### **The Week's Cultural Notes.**

The *Pleiones*, or Indian Crocuses, are very pretty and bright when in flower, and as the earlier species are now opening, it is time to draw attention to them. Directly the flowers are past the plants begin to grow and root. Or perhaps it would be more correct to say that the formation of the flower is the beginning of the growing season. At all events, root action immediately follows, and unless these are to be checked, repotting must follow close on the heels of flowering. They are grown in a variety of ways, but the usual mode is in small, flattish pans holding from a dozen to twenty bulbs.

The compost may consist of equal part peat and loam fibre, a little chopped sphagnum, and a sprinkling of finely broken crocks. Near the drainage place a layer of rough moss, covering this again with a thin layer of compost. Then pull the old plants to pieces, laying all the new pseudo-bulbs together, and removing all but a few of the old dead roots. Plant them evenly all over the surface of the pan, rounding the compost a little, and allowing the base of the new bulb to just enter the compost. The few old roots left will serve to steady the plant in position until new ones form.

Beyond a single watering to settle the new soil about the roots it is not wise to moisten *Pleiones* after repotting until root action is free. Then a gradual increase is necessary, a large amount being required in the growing season, and a very moist atmosphere. Other dwarf cool house Orchids advancing for flower, such as *Sophranitis grandiflora*, should be kept just moist, an excess of moisture or dryness just now being undesirable. When cold winds are blowing very little ventilation will be needed, but during damp, mild weather keep plenty of air on, and just warm the pipes to keep it moving.

When *Miltonia spectabilis* and nearly allied kinds have been grown in the cool house during the summer, it will be wise to remove them now to slightly warmer quarters. If none are at command, keep them well on the dry side, and out of the reach of draughts all through the winter. The yellowish tinge seen in the foliage of these Orchids seems quite natural to them, even healthy plants carrying it. More, perhaps, than any other Orchids, they like an equable moist and mild temperature the whole year through, and in winter sufficient root moisture to keep the pseudo-bulbs plump.

*Lælio-Cattleya* *Cooksoniæ*.

An early opportunity should be taken to perform the usual winter cleaning of the houses. The woodwork and stagings may be repaired and fresh gravel or material used in place of the old.—H. R. R.

## Culinary Apples.

### An Estimate of a Dozen Varieties.

**KESWICK CODLIN**, as an early August variety for cooking, still remains one of the best. Its quality is first class (some people like it for dessert), and the tree succeeds well as a bush in the garden or as a standard in the orchard.

**STIRLING CASTLE**.—As a bush tree for the garden or the field, grown on the English Paradise stock, this is one of the most prolific and profitable August and September Apples that can be grown. A real poor man's friend.

**FROGMORE PROLIFIC** is another September Apple which should find a home in every garden. It is one of the heaviest and most consistent cropping Apples we have.

For October and November we have a wide selection, and the following may be relied on as excellent from every point of view:—

**GRENADIER**.—A large, yellow, handsome Apple, by many esteemed as the best October and November variety. It is very prolific, and excellent to grow for market.

**ECKLINVILLE SEEDLING**.—A well known variety. One of the heaviest cropping and best orchard sorts we have.

**STONE'S APPLE**.—This is another large, handsome October variety. It is light yellow in colour, with a faint flush of red on the sunny side. It is a good bearer, and a popular market sort.

From November to the end of January the following are the best:—

**LANE'S PRINCE ALBERT**.—One of the best known sorts, and certainly one of the most consistent and heavy croppers of any we have. No garden or orchard should be without it.

**BLenheim ORANGE**.—Grown as bushes on the English Paradise stock it succeeds admirably, crops regularly and heavily, even on comparatively young trees. Grown in this way it is as well suited for dessert as it is for the confectionery. When grown as a standard in the orchard on the Crab stock the tree attains to a great size, and returns valuable crops most years; but as a young tree in the orchard on this stock it is usually a long time before it reaches a state of fertility. This drawback notwithstanding, no orchard should be without this—one of the handsomest and noblest of Apples.

**BAUMANN'S RED REINETTE**.—A fruit of medium size, of attractive colouring, very prolific, and first class quality.

From January to May the following are amongst the best:—

**ROYAL LATE COOKING**.—A large, heavy, handsome, yellow variety. The tree is a strong grower, prolific cropper, excellent for dessert late in the season, and will keep sound and good way into June.

I have only two more varieties to mention, and the difficulty I have in the richness of selection at hand is to know which to leave out and which to include. Wellington, as one of the best known and best esteemed, naturally suggests itself as having claims for this time of the year superior to any other. I am sorry not to include it in my twelve, and the reason is that it is not a consistent bearer, and the tree is not an over-good grower; but the strongest reason of all is in the fact that Wellington and Blenheim Orange, between them, as parents, have given us an Apple which is in every way superior to Wellington, namely:—

**NEWTON WONDER**.—I don't know to whom the credit of raising this variety belongs, but whoever he may be he may justly feel proud of having been the means of giving it to the world. [Messrs. J. R. Pearson and Sons, Lowdham, Notts, were the introducers of it, a member of the firm having discovered it at a Midland show.—ED.] It is one of the best and most valuable Apples in cultivation. Its cooking qualities are very much like, and equal to, Wellington, and its handsome and attractive appearance equal to the best samples of Blenheims, and this is saying a great deal. It is one of the strongest growing Apples we have, and for bushes grown in the garden should be worked on the Paradise stock. It is in season from March to the end of May.

If it had not been that I have pledged myself to mention only twelve sorts, I should have said that the only variety worth growing for the purpose of making mince-pies is Royal Russet, and I am sure your Irish readers would never forgive me if I did not include Chelmsford Wonder, a variety highly esteemed in the Green Isle. This is only a diversion, and I must proceed to give my latest and last choice of the twelve, and this must be in favour of **STRIPED BEAUFIN**. This is a handsome and attractive variety, and towards March and April is excellent for dessert.—O. THOMAS.

## A SEEDLING GOOSEBERRY.

On page 377 there is illustrated a single shoot from a seedling Gooseberry raised by one who has long been a reader of, and contributor to, this journal. He writes as follows: "The enclosed photo is a branch from a seedling Gooseberry, with eighty-two fruits upon it. There are four other branches on the tree bearing fruit in a similar manner. The photo was taken before the fruit was fully grown, and you may remember that I enclosed the top of one of the other branches with ripe fruit for you to see when I sent the photo. [A laden branch.—ED.] The tree is grown in the cordon style. I have raised a number of Gooseberries, Strawberries, Raspberries, Apples, Cherries from seed, &c., and I have been cross-breeding with a great number of flowers. I have also tried a number of experiments, for the last forty years, with plants, seeds, &c., and regret I cannot find time to send more than occasional notes to the *Journal of Horticulture*.—W. B."

## STRAWBERRIES IN POTS.

Successful Strawberry forcing depends largely on the treatment the plants are subjected to during their preparatory course, and especially at what is known as the resting period prior to starting. The wintering of Strawberries in pots by stacking them one upon another in sawdust or other material against a wall, or housing them on the border of fruit houses, is not only unnecessary, but absolutely injurious, as the soil not unfrequently becomes dry, and the currents of air induced by the free ventilation, waste the energies of the plants. The forwardest will now have the crowns well developed and the pots filled with healthy roots. To preserve them is a point of some importance, as when they get frozen and suddenly thawed their collapse is certain, and the plants start badly in consequence. If intended for early forcing, they will be the better for having the lights of a frame placed over them, the pots being plunged in ashes or cocoa-nut fibre refuse, or even tree leaves, but not so as to heat. The lights must be withdrawn in mild weather, and only used in case of heavy rains, when they must be tilted, as in case of frost.

The plants should be regularly examined for watering, supplying it only to such as stand in need, never allowing them to suffer, as the Strawberries are much injured when allowed to become dry at the roots. Place late plants in a raised bed, or plunge in ashes or other material on the flat in a sunny position to finish the ripening process, and they will require to be duly supplied with water. If any plants remain long without needing a supply, or the soil becomes very wet, examine the drainage, rectifying it wherever defective, expelling worms with lime water. Sun and sharp frosts ripen the growths and solidify the crown better than the atmosphere of houses.—G. A.

## A REMEDY FOR THE CODLIN MOTH.

When recently visiting Mr. Thomas Pendered, at Redwell, Wellingborough, and while inspecting his crops of fruit, he informed me that he had pretty well cleared his garden of the codlin moth, though at one time it was badly infested with it, as it adjoined a garden in which its ravages were largely apparent. Mr. Pendered stated that when he finds it necessary to take remedial measures, he requests a chemist to mix him a quantity of dressing compound, composed of two parts of black sulphur to one part of softsoap; say, 2lb of the sulphur to 1lb of softsoap; it is then placed in a tin ready for use. A portion of this is placed in a pail, and sufficient boiling water poured over it to form a kind of batter, and to this is added a half pint of carbolic acid, and the whole is stirred up well together. It is also constantly stirred during the time of using, to prevent the sulphur sinking to the bottom.

The mixture is applied to the trunk and branches of the trees by means of a brush at the end of a long handle, such a brush as is employed for tarring a fence; and by means of the brush the compound is well rubbed into the crevices in the bark. This dressing is applied during February and March. In addition to the dressing applied to the trees, the soil about them is dressed with one part of soot to two parts of quicklime. Mr. Pendered employs half a ton of soot and one ton of lime to an acre of orchard trees. A sweep is employed to sow the soot first, and the lime is spread over it. These are put on the soil in early spring, and allowed to remain on the surface till washed in by rains. After a time the surface may be gently forked over with advantage. Mr. Pendered stated that he had found this remedy most successful. He states that he gathered seven bushels of Apples from two trees, and he thinks there was not one among them pierced by the maggot. The application of lime and soot is given once in three or four years.—R. D.

## Lilies of the World.

(Concluded from page 365.)

**PHILIPPINE ISLANDS LILY.**—So far, these islands have only given us one species of Lily, and that one is of extreme beauty. Now the country is being opened up, soon collectors will take to despoiling Nature. Up-country we may look for many fine species coming from this interesting group of islands. *Philippinensis* flowers in the way of *L. longiflorum eximium*, but more refined and delicate looking. The first time I saw this fairy-like Lily I measured it, and found it 10in long. It is a greenhouse plant in Europe, but I think it could be grown outside in South Africa.

The only Lily I have seen growing in the gardens about Cape Town is *L. longiflorum eximium*. It would therefore, appear that amateur gardeners have not yet taken up the culture of this most delightful family. I will, therefore, name three selections, each one containing different Lilies from the other lists, with the view of meeting the convenience of all as regards outlay. No. 1 selection is the least expensive; No. 2 next; No. 3 the highest priced—while all are equally beautiful. Any one of the lists are a good selection, and all the lists put together will make a really handsome collection. I have omitted *L. candidum* from the lists, as it should be despatched from England in August or September; not later, if possible, and on arrival planted at once.

On arrival they can be placed in a box of semi-moist earth, and kept in the coolest place possible till the weather cools a little, and once a week they should be examined to discourage root growth, and to see they are not suffering in any way; or they may be planted in kerosine tins, covered with at least 4in of soil, and the tins well drained—the tins kept in the coolest place at command, and there remain till the flower buds are formed, when the tins may be placed on the stoeps. If planted in pots, let the pots be plunged to the rim in coal ashes in a cool place, and remain till in bud; then the pot in which the bulb is growing dropped into a larger pot, and then placed on the stoep. The soil in all cases should be moist, but never wet, except in the case of the moisture-loving Lilies, which should get an increase of moisture when growing. So treated, you can enjoy the Lilies as an ornament to your house, and can decide from their habit of growth the best place to plant them out in your garden when the time to plant out arrives.

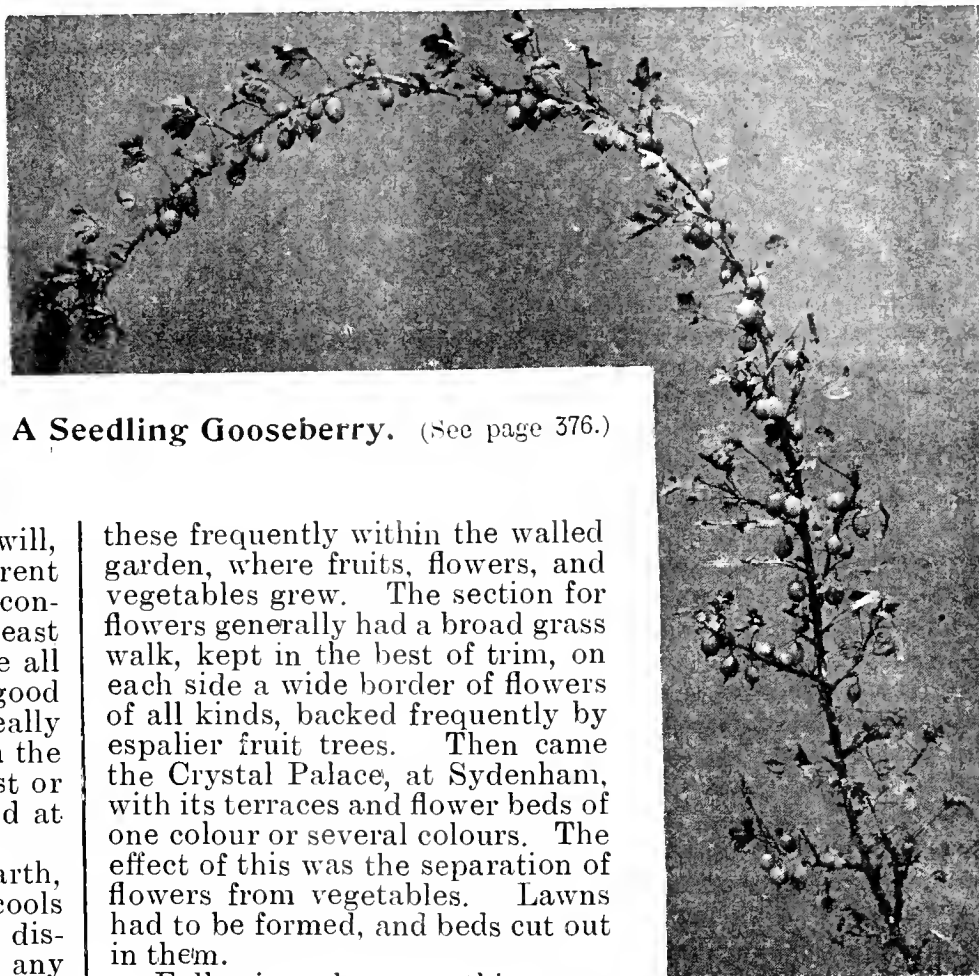

No. 1 selection: *L. auratum* type, *L. Browni*, *L. canadense flavum*, *L. chalcedonicum*, *L. croceum*, *L. davaricum erectum* and incomparable, *L. longiflorum robustum*, *L. Martagon dalmaticum*, *L. pardalinum* type, *L. pomponium*, *L. speciosum roseum album Kraetzeri*, *L. speciosum rubrum Melpomene*, *L. superbum*, *L. testaceum*, *L. tigrinum splendens*, *L. elegans Beauty*, *L. elegans Van Houttei*.

No. 2 selection: *L. auratum platyphyllum*, *L. auratum Virginale*, *L. davaricum Sappho*, *L. Hansonii*, *L. Humboldtii*, *L. Leichtlinii*, *L. Martagon album*, *L. pardalinum Bourgæi*, *L. Parryi*, *L. speciosum punctatum album*, *L. speciosum purpureum*, *L. tigrinum*, *L. Fortunei* (single and double), *L. elegans Batemannæ*, *L. elegans Prince of Orange*, *L. elegans G. F. Wilson*, *L. canadense rubrum*, *L. elegans Sunset*.

No. 3 selection: *L. auratum pictum*, *L. auratum rubrovittatum*, *L. Bolanderi*, *L. Columbianum*, *L. giganteum*, *L. Henryi*, *L. japonicum odorum*, *L. monadelphum Szovitzianum*, *L. napalense*, *L. pardalinum Michauxii*, *L. parvum*, *L. speciosum album Crown Princess*, *L. speciosum punctatum*, *L. speciosum rubrum multiflorum*, *L. sulphureum*, *L. elegans Alice Wilson*, *L. elegans robustum*, *L. elegans Wallacei*.

The opening remarks in this Lily reading, with the three selections of Lilies I have made, will, I think, be of service to those who may take up Lily culture, whether as amateurs or professional gardeners. The selections and directions represent the experience of one of the very earliest cultivators of Lilies since they last came into vogue; we must not say "fashion," that word properly belongs to ladies when referring to the latest fashions in bonnets, &c. The word fashionable may also be applied to colours in cut flowers, as they rank fairly as floral millinery, but to use such terms to our garden plants is too shocking.

From time to time there are changes in the arrangements of gardens, gardening being a progressive art, and plants have to be sought out to meet all new arrangements. I remember sixty years ago we had only flower borders, and

A Seedling Gooseberry. (See page 376.)

these frequently within the walled garden, where fruits, flowers, and vegetables grew. The section for flowers generally had a broad grass walk, kept in the best of trim, on each side a wide border of flowers of all kinds, backed frequently by espalier fruit trees. Then came the Crystal Palace, at Sydenham, with its terraces and flower beds of one colour or several colours. The effect of this was the separation of flowers from vegetables. Lawns had to be formed, and beds cut out in them.

Following close on this came Nesfield's ideas, which were illustrated in the gardens of the Royal Horticultural Society, South Kensington; very low Box edgings, used in the formation of the beds, and instead of flowers, pebbles, coloured stones finely broken up, bricks reduced to rough powder, broken glass, and different coloured substances. This held on for a short time. Then came Mr. William Robinson's denunciation of the whole system of flower gardening, and he preached from the house-tops hardy herbaceous plants. After some fifteen or twenty years' pegging away on the one text, people began to think there was something in all the noise, and this brought about a great revolution. Carrying out reforms is generally done by a compromise; so now we have flower beds, carpet beds that vie with Paisley shawls in design, flower borders galore, and, as at Park Lane side of Hyde Park, tropical plants let into the grass, such as Palms, Bananas, &c., &c., while beds of Carnations, Roses, &c., are seen everywhere. And in spring beds full of Hyacinths, Tulips, Daffodils, Pansies, Violas, Crocus, &c., &c. The Park Lane side of Hyde Park is a paradise of flowers, when there is sufficient sun to open them, and enough heat to keep them alive. In the Cape Peninsula you have twelve flower months in your calendar. Surely Paradise must have been in this favoured land.—PETER BARR, V.M.H., Cape Town.

## PINEAPPLES.

All young plants should now be arranged so as to obtain the fullest benefit of light and air. As the sun diminishes a corresponding diminution of temperature should take place at night until it reaches the winter standard of 55deg to 60deg at night and 65deg in the daytime. Ventilate freely whenever the external conditions are favourable, paying particular attention to watering. An inspection of the plants should be made once a week, and whenever a plant needs water supply it copiously at about the same temperature as that of the bed.

Plants on which fruit are now appearing will perfect them at a time when other fruits are scarce, and should therefore be afforded a good position in the fruiting house. Continue 70deg as the minimum temperature in the fruiting house, though on cold nights a decline of 5deg may be allowed and 5deg more in mild weather, 75deg artificially by day, and 85deg to 90deg from sun heat, closing the house at 80deg, sprinkling the paths as may be necessary when they become dry, and on sunny afternoons an occasional syringing will be advantageous, keeping the bottom heat regular at 85deg to 90deg.—PRACTICE.

### Pompon Chrysanthemums.

Pompon and Anemone Pompon varieties, such as those illustrated on page 383, are well suited for amateurs or small growers, and they are favourites to a large extent with market men and florists, on account of their neat habit of growth and profusion of bright flowers. They stand a deal of knocking about, and are useful for cutting from. Pompons are generally very much neglected in private gardens, where their several merits might win for them more appreciation and variety of employment. For decorative use they are best grown as bushes, cuttings being inserted during December or January, and the plants grown on in the usual manner, but confined to pots, 6in in size at the largest, unless a dense bush is desired. Bush plants are topped when 4in high. Those intended for tall bushes should have three of the strongest shoots selected, which should be allowed to extend, retaining all side shoots. These are not topped, but are allowed to throw out their abundance of flowers. As tall bushes, the Pompons are exceedingly attractive.

### Chrysanthemums at Cardiff.

A few days since, in response to an invitation from Mr. G. Williams of Manor House, Cardiff, I had the pleasure of looking over the very up-to-date collection of Japanese Chrysanthemums grown by his foreman, Mr. J. Howe, a very old and successful exhibitor at Cardiff and elsewhere. I found a very well grown and uniform lot, comprising over 800 plants, which amply testified to Mr. Howe's skill as a cultivator. The following are the chief varieties: H. E. Hayman, May Vallis, Mad. P. Radaelli, J. C. Neville, Mrs. Emma Fox, very dwarf; Matthew Smith, in fine form; Lord Salisbury, Mafeking Hero, Miss Alice Byron, W. R. Church, Lord Ludlow, grown from cuttings struck in February, and carrying one bloom in an 8in pot; Mons. Ch. de Léché, thirty plants, for one bloom each, in 8in pots; Florence Molyneux, very good; Mrs. Barkley, twenty-four grand plants; Mrs. J. J. Thorneycroft, C. J. Salter, splendid; L. Mountford, Nellie Perkins, Calvat's '99, Mrs. Greenfield, Rev. W. Wilks, Ben Wells, Duchess of Sutherland, Hettie Dean, Miss Ethel Fitzroy, very promising; Mrs. T. W. Pockett, one of the new Australians; Godfrey's King, a regular young tree; Queen Alexandra, Sensation, nice habit; Exmouth Crimson, Godfrey's Triumph, another tree; Gen. Hutton, very tall; Masterpiece, Godfrey's Pride, and C. McInroy.

The whole of Godfrey's new ones are conspicuous for their grand habit and growth. There were also Hy. Barnes, a rather tall grower, but vigorous; Mrs. A. Macdonald; C. Penfold, W. E. Vowden, Mrs. E. Hummell, Dr. Pywell, tall, but good; Mr. G. Lawrence, Miss Jarvis, Mrs. H. Emmerton, Mr. R. Clayton, C. Jarvis, and a fine batch of Mad Carnot, and its sports were noticeable amongst the older varieties.

I failed to find any trace of rust, and even should it appear, I don't think it could do much harm now to such robust plants. Mr. Howe was busy bud-taking, and I am looking forward to paying him another visit when they are in bloom. If the present promise is fulfilled, a journey of fifty miles should be worth undertaking for the sight.

A few days afterwards I was in London with a few hours to spare, so I ran down to Earlswood and paid Mr. Wells a visit, and was amply repaid for the journey. I had not time to make more than mental notes, but some of those made a lasting impression. Mr. Wells has a most promising lot of Mr. Pockett's Australian seedlings; several of them reminded me of T. Carrington and Pride of Madford. They were all under number, but H1 and H2 made lasting impression, as did Hy. Barnes, Mrs. T. W. Pockett, Donald McLeod, which Mr. Molyneux mentioned to me last winter as a good one, but I could not find it, for the simple reason that it is not yet in commerce.

Ben Wells seems to be a favourite from the number grown. Mr. Godfrey's new varieties were all in fine form and confirmed my previous opinion of them. Mad. Herewage, and its parent Australia, grow to a great height here. After seeing the plants in pots, we paid a visit to a piece of land adjoining the sewage farm, where Mr. Wells grows the early flowering varieties, some of which were in bloom. Goacher's Crimson struck me as being a particularly desirable market variety, and Parisiana looked a useful white. Mad. Marie Masse and its sports made a brave show.

All the exhibition varieties are also planted out for stock plants. Mrs. T. W. Pockett, of which Mr. Wells had a large batch growing in the open, looked splendid, and is worth trying,

but not at half-a-guinea a plant. Darkness coming on compelled me to get away, and doubtless Mr. Wells was thankful that "the pumping process" was at an end.—A. H.

### New Town Nurseries, Bedford.

A visit to Mr. Isaac Godber, who is a grower of Chrysanthemums, &c., for market, which are successfully grown in open quarters. These remarks are confined to a few varieties considered worthy of growing, and useful for early market and mid-season work. First comes Madame Marie Masse, the earliest pink flowering variety in cultivation. The Masse family are good for free and early flowering, being of good sturdy habit and requiring no stakes. Crimson Masse is a bronze crimson sport from Madame Marie Masse, and is a good useful variety. Ralph Curtis Improved is white, or creamy white; it is a sport from Madame Marie Masse, and is quite distinct from Ralph Curtis, being much more vigorous and free. Horace Martin, a bronzy yellow, is early and a good traveller. It is sure to supersede yellow Madame Desgranges as a market variety. Its habit is good and free.

Market White furnishes a grand variety, and of great substance of bloom: a very free flowerer, and pure white; September and October. Crimson Masse is the least vigorous of the family; the other varieties, the pink Madame Marie Masse, the creamy white Ralph Curtis Improved, and the yellow Horace Martin, are all exceptionally vigorous and free. The old Madame Desgranges (creamy white) and the yellow or Geo. Wernig variety are still grown in limited quantities at New Town Nurseries, Bedford.

Harvest Home, red, tipped with gold, is a very distinct variety, and has been a favourite as an early bloomer for several years, but its popularity with market growers is on the wane. The blooms are best cut before they are fully open. White Quintus, a pure white sport from O. J. Quintus, has a good habit and is a free flowerer. The blooms were just opening when my notes were taken in early October.

Ryecroft Glory is an old favourite October yellow, its habit and vigour being all that could be desired. Roi de Preeoces, a bright velvety crimson, should be cut before fully open; it is good, vigorous, and free; September and October. Vice-President Hardy, fiery chestnut, vigorous habit, a striking and distinct variety; its splendid habit makes it a favourite for cut flowers; September and October. Golden Queen of the Earlies, a deep yellow sport from Queen of the Earlies, with all the good points of its parent, comes in October.—G. R. A.

### A FINE LAPAGERIA.

One of the finest, if not the best, of these choice summer plants I have seen is the roof-trained specimen growing in a greenhouse in Colonel Brymer's garden, near Dorchester. Colonel Brymer's name has been familiarised by its association with choice Orchids for years past, notably Dendrobiums and Cattleyas, one each of which bears his name, and his collection of these plants, together with hybrids of his own raising, is likely to be handed down to future posterity. Orchids here find a congenial home. Many fine specimens of great value are to be seen beside quantities of smaller growing species. The raising of Orchid seedlings, too, would seem to be taken up with zeal and success, judging from the tiny specks on flannel seed-beds, and others ranging in differing stages to that of the matured specimen.

The object of this note, however, is not Orchids, but Lapagerias, which to many beside myself have been a source of admiration by reason of its wealth of flower, its fine form, and deep colour. The plant occupies a corner of the house near the back wall, and the vigorous shoots rise to the roof above and spread along its entire length of some 80ft or more. The picture displayed is a striking one, for flowering shoots depend from the roof with such profusion and regularity that the whole house seems aglow with colour. Little stone weights fixed to the points of the shoots as they begin to grow in spring prevent them curling round the wires or rising to the roof glass above, and though much time and trouble is thus entailed, it is more than repaid in the pleasing character which their drooping trails of flowers convey.

The aspect of the house is north, with a lofty wall behind, which affords shade and conditions such as the Lapageria enjoy. Certainly there is in this instance an embodiment of an ideal equipment for the growth of such a fickle plant. There must have been many hundreds, if not thousands, of these chaste and wax-like flowers hanging at one time, and how long it had been so, or to what period of the future it would extend, it does not voluntarily occur to the visitor when allowed the privilege of an inspection of such a fine, natural picture. The plant itself is a living compliment to the gardener, Mr. Powell, and not less so to his foreman, Mr. Denny, who has had the charge of it for several years, much to his own and employer's satisfaction.—W. S.

# NOTES & NOTICES

## Journal of the Royal Horticultural Society.

Part 1 of the twenty-seventh volume of the above has been published, and contains a number of excellent and very useful articles on gardening, botany, and other cognate sciences by experts. The volume is well illustrated and contains some coloured plates illustrative of plant diseases.

## King Edward's Gift to Horticulture.

It is with the greatest satisfaction that we print the following letter, which we take from the "Times" of Thursday, October 16, our publishing day: "His Majesty the King, having heard of the project in hand, has commanded the following letter to be sent to Captain Holford, C.V.O., C.I.E., a member of the Council of the Society, enclosing His Majesty's contribution of 100 guineas to the fund:—

"Balmoral Castle, September 30, 1902.

"My Dear Holford,—The King has been much pleased to hear of the intention of the Royal Horticultural Society to commemorate its centenary in 1904 by the erection of a new horticultural hall for the use of the Society.

"I showed the King Sir Trevor Lawrence's letter, and His Majesty commanded me to tell you that he perfectly remembered having addressed the Society in 1890 as Sir Trevor states; and you are to tell him from the King that the words His Majesty spoke in 1890 he repeats now, if possible, with a stronger feeling than ever, not only of the desirability, but of the actual necessity of such a building as it is proposed by the Society to erect. Sir Trevor and the Society, the King commands me to say, have His Majesty's best wishes in their undertaking, and, as a small donation from His Majesty by way of showing the interest he takes in the Royal Horticultural Society, I am now commanded to forward you a cheque for 100 guineas towards the fund which is being raised for the new building.—Believe me, my dear Holford, very truly yours,

D. M. PROBYN.

"To Capt. George Holford, C.V.O., C.I.E."

"Subscriptions may, if desired, be made payable half at once and half at midsummer, 1903. Cheques should be drawn in favour of the Royal Horticultural Society, and crossed 'London and County Bank.' W. WILKS, M.A., Secretary.

"117, Victoria Street, Westminster."

## Prince of Wales and "The Hall."

Following the King's gift announced in the above paragraph, we learn from the "Morning Post," of Wednesday last, that the Prince of Wales has graciously contributed £50 towards the Horticultural Hall fund.

## A National Park.

What is described as a National Park, 108 acres in extent, was opened with no little ostentation and the gracious smiles of royalty on the 16th inst. The spot is the Brandellhow Estate, on the shores of Derwentwater, a scene of beauty, as all the scenes in Lakeland are. The movement is certainly deserving of praise, and the promoters deserve the thanks of the nation for their patriotic endeavour. But surely the opening of this National Park, 108 acres in extent, might make people think. It is but a mere clipping, less than a small farm, and hardly larger than a Highland crofter's holding. Is this the only strip of hillside in England which the nation can call its own? Is every mountain top in England, Scotland, Wales, and Ireland private property, from which an inoffensive tourist, seeking health and the privilege of looking upon the face of his native country, may be warned off by a gamekeeper? In the Scottish Highlands there are thousands upon thousands of acres of mountain to which the present possessors are said to have no better title than a Court of Session judgment settling disputes about "marches" among themselves or their grandsires. It is too late to assert the right of every Briton to the mere privilege of roaming these solitudes, and ascending mountains sacred to the red deer, the blackcock, and the eagle.—(The "Leeds Mercury.")

## Scottish Horticultural Association.

Members' subscriptions of 2s. 6d. for the current year are now due. All members who pay their subscription before November 1 are entitled to a season ticket for the Chrysanthemum Show. Members who have paid ten annual subscriptions may become life members by the payment of One Guinea.—W. MACKINNON, Treasurer, 144, Princes Street, Edinburgh.

## Birches Diseased in Epping Forest.

A peculiar disease has made itself manifest among some of the Silver Birches in Epping Forest, which have been attacked by a fungus growth. So far the mischief caused is not on the extensive scale suggested a day or two ago by a contemporary. There is no probability of Silver Birches dying out in Epping Forest, where they flourish in large and increasing numbers, especially in the direction of High Beech and Theydon Bois.

## Convicts for Road-making.

At the present day, in the southern States of North America they employ the convicts in gaol, or such as are able and only in for short terms, in building new roads or rebuilding old ones, and they find the system beneficial to the counties and to the prisoners also, who, by labour out of doors, acquire a vigour and strength and capacity for earning an honest living that they would not gain in the cells. This is said to save much money every year. It also helps to keep the tramps, who have a constitutional disinclination to hard labour, away from that section.

## Seeds and Plants for the Argentine Republic.

The importation of plants and seeds into the Argentine Republic is permitted under a special law of July this year, says "Commerce," subject to previous inspection, and to disinfection or destruction as the case may require. Regulations have been made which amplify the law, and from which it appears that Buenos Ayres is the only port at which such importations may be effected. Persons desiring to import plants or seeds are required to address a petition to the Agronomical Section, setting forth the name and address of the importer, the name and place of origin of the plants or seeds, the means of introduction and date of arrival, and the purpose and (if possible) the place for which the goods are intended.

## Californian Crops.

The weekly report of the U.S. Weather Bureau says that Grapes and late deciduous fruits have ripened rapidly in most places, and the crops are being gathered and cured as rapidly as possible. The fruit and Grape crops are remarkably heavy in nearly all sections, and in some places the largest ever raised, but owing to the scarcity of labour and refusal of some of the canneries to handle the fruit, there will be a heavy loss, especially of Peaches, which ripened rapidly. Raisin growers are said to be short of trays, and some of the Grapes will be sent to wineries. Present indications are that the Grape crop will be above average. Prunes are yielding heavily, but are small in size in some localities. Apples of excellent quality are plentiful. The Almond crop is unusually heavy. Citrus fruits, Almonds, and Walnuts are in good condition. Hops are yielding an excellent crop in the northern counties. Corn, Potatoes, Beans, and sugar Beets are doing well.

## Waste in Edinburgh Public Gardens.

A correspondent to "The Scotsman" writes as follows:—"May I, through the medium of your columns, draw attention of our City Fathers to what I think is a shameful waste in our public gardens of valuable plants, viz., Pelargoniums, Fuchsias, &c., which at this time of the year, when taken up to make room for spring flowers, are thrown into the rubbish heap. Now, instead of allowing such plants to rot, might I respectfully suggest to the Corporation that they would give instructions to their gardeners to send these plants, also any surplus plants that they may not require, to the Board schools to be distributed amongst the pupils, who, I am quite certain, would be delighted to have them. I would also invite ladies and gentlemen that have private gardens within the city and neighbourhood to send their spare plants for the same purpose. By so doing they would have the thanks of many school children." London parks always dispose of their bedding plants by free distribution.

**Appointment.**

Mr. C. H. Holloway, late head gardener, Kilmeston Manor, Alresford, as head gardener to the Right Hon. Lord Aberdare, Longwood, Winchester.

**Horticultural Teaching in Scotland.**

The Dundee and Broughty Ferry district (Forfar) have taken the lead for years past in providing instruction in horticulture by means of lectures. The first of a course of lectures under the auspices of the Technical Education Committee and the Dundee Horticultural Association was given in the Grove Academy on the 15th inst. The lecturer was Mr. Robert Dow, Longforgan, who had for his subject "Our Common Mushrooms, and How to Know Them."

**A Nursery Decision.**

The following note from the American "Florists' Exchange" is interesting:—"At San José, California, the superior court recently rendered a decision and judgment, which makes it obligatory on a nurseryman to sell fruit trees that will grow, bear fruit, and approach a general standard. About a year ago, L. P. Brackett, a fruit grower of Santa Clara County, bought some Prune trees of M. Martens and set out three acres. After three years of care and culture, the trees, which never had made but a moderate growth, died. Suit was brought against the nurseryman for damages, and the judgment rendered is for \$1,500. The suit turned on the word 'merchantable.' Expert testimony was furnished to show what a fruit tree must be to reach the standard expected by the law. The court decided that any person who is deceived into buying trees that only cumber the ground, but never thrive or bear fruit, is entitled to be recompensed to the actual amount of the loss sustained. The above clipping sets one thinking. The court's decision, inasmuch as it relates to a person's being deceived into buying trees, &c., is sound; but from what appears in the clipping it is not clear that the seller of the Prune trees deceived the buyer. That it took three years for the trees to die ought to be good proof that they were in a pretty good condition when planted. Too much depends on circumstances of soil, situation, moisture and general treatment, to make it safe for a nurseryman to obligate himself 'to sell fruit trees that will grow, bear fruit, and approach a general standard.'"

**Appointment to Mr. T. R. Sim.**

Mr. T. R. Sim, who was recently voted a grant of £250 by the Cape Government for a work on Forest Flora, is the eldest son of the late Mr. John Sim, Gateside, Strachan, Aberdeenshire. He received an excellent education at Aberdeen Grammar School, on the completion of which he obtained a splendid training in his adopted profession at Kew Botanic Gardens, London. About fourteen years ago he left Banchory, and was fortunate in securing an appointment as curator of the Botanic Gardens, King William's Town, where in the new field opened up to him he gradually acquired an extensive and varied knowledge of his pursuit as relating to Cape Colony. His work on "The Ferns of South Africa" is regarded as the standard work on the subject, and many other valuable contributions, including a handbook of "Kaffrarian Ferns," have earned for him a high place in his profession. His latest work, the value of which as already stated, has been recognised in a tangible way by the Government grant of £250, is on Forest Flora, and is received as a valuable addition to the science. Some time ago he was given an Important Government appointment in the Forestry Department, where he gained great distinction, and was repeatedly promoted, and only recently the Government, which for some time has had under consideration the future management of the forests, and the laying out of new plantations in Natal, made an offer to Mr. Sim of the responsible position of Conservator of the Forests in Natal, and which Mr. Sim has now accepted. As a scientist, Mr. Sim has risen to a position of great eminence, and to-day is recognised as one of the foremost botanists in South Africa. He is a member of the Royal Agricultural Society, London; the Linnæan Society, &c. Before leaving for South Africa it may be recalled he was the jubilee gold medal essayist of the North of Scotland Horticultural Association. In South Africa he, at an early stage, was successful in winning the first prize for an essay on irrigation, being one of the series of competitions inaugurated by Cecil Rhodes, who was Premier at the time.

**The Scottish Heather in Canada.**

One of the most interesting emigrants from Scotland last year was a plant of Scottish Heather, transported root and branch with the object of founding a new colony in Canada. It was sent by Mr. Eliot, of Goldenacre, snugly packed in a special case with special precautions to ensure its safe arrival; and Mr. Henderson, the Town Clerk of Ottawa, who acted as emigration agent at the other side, now writes to say that the newcomer has justified its hardy upbringing. There need be no fear but the Heather will stand the rigour of a Canadian winter. It needs no encouragement.

**Begonia Flowers from Norwood.**

No firm in or around London has done more to exhibit the merits of the tuberous Begonia in its varied colours than Messrs. John Peed and Son, of Roupell Park Nurseries, South Norwood. During the week the Messrs. Peed sent to us a selection of blooms picked from plants grown all summer, and growing still, in the open. Even now, the third week in October, these flowers measure 5in across, are stout and dense in substance, smooth, even, and well opened, and, lastly, possessing remarkably fine colours. The varieties are orange, scarlet, white, crimson, pink, and salmon. The best effect with these is obtained by harmonising colours that are nearly alike.

**Orchards.**

To the townsman there is nothing about a farm of greater charm than the orchards, which are very beautiful when covered by their snowy blossom, and again, later, when drooping below a load of purple and golden fruitage. Few townsmen know how gloriously beautiful are the orchards of Somerset and Devon in late September, for few make holiday then; but those who do for once, have always in their memory pictures of heavy-fruited orchards, trees laden with fruit of rich red and gold, and heaps abundant beneath the old gnarled trees of ruddy glowing Apples, like sparkling fires among the grass. It is generally granted that fruit trees are ornamental as well as useful. Could they not be planted more frequently in shrubberies?

**The New Riviera.**

Messrs. Elder, Dempster, and Co. have adopted the above heading in advertising their Jamaica hotels and the Imperial Direct West India Mail Service, which the firm established at the beginning of last year. This title for Jamaica is likely to attract attention from those in the habit of visiting the Riviera, and a change of programme for the winter and early spring months would be found beneficial to frequenters of "the sunny South." Too much is not claimed by any means in the classification, by name, of the beauties and health-giving properties of Jamaica, for that land of bright sunshine in the Caribbean Sea provides the most marvellous and beautiful scenery, and every shade of climate that man can desire. In lieu of the pretty villas of Italy which dot and relieve the landscape, the picturesque homes of the planters beautify the scenery of Jamaica. The new portion of the Constant Spring Hotel is to be opened December 1 with a garden party and other entertainment.

**Notes from Beaulieu, N.B.**

The weather here is very much of a piece with that of the southern counties. The difference in latitude in no appreciable degree can be detected in any of the general forms of vegetation. There is, however, one natural feature which excels immensely anything of the kind to be met with this season in the southern counties, namely, the autumn tints in the foliage. I, to-day, stood on a commanding eminence overlooking the mammoth building of Beaufort Castle, the seat of Lord Lovat. It lies on the banks of the river Beaulieu, in an extensive basin, probably, where in former ages the waters of the Firth of that name lashed their waves against the encompassing walls of Nature's munitions. This extensive, undulating area is more or less covered with forest trees, comprising all kinds, and consequently all shades, from the deep red of *Cornus sanguineum* to the soft primrose of the weeping Birch and emerald green of *Quercus*. I do not remember of ever seeing a more pleasing prospect, and truly a visit to this part of the Highlands is worth the expense and time it entails.

## Botanic Gardens.

In reading the history of botany and gardening, we are struck with the quaint ideas which first prevailed regarding plants and their uses, especially those used in medicine. Both gardening and botany, we learn, had very small beginnings. The former was merely the cultivation of such plants as were found wild, and snited either as food or clothing for man. Botany began to be studied by the old physicians, who used many plants in their prescriptions. History, however, gives us no idea of the number of victims who succumbed to their crude experiments, not to mention the many superstitious notions regarding their virtues or properties. The herbalists (and they are not yet extinct) considered that every plant was created for man's use, either as food, fuel, medicine, or manufactures; hence it is quite easy for us to conceive how these plants, when their uses became known, should be cultivated. Those yielding fruit, food, &c., fell to the lot of the farmer or husbandman, and those which were used in medicine were grown by the physician or apothecary.

Some of the old historians were learned in many subjects, from medicine to astronomy, or they might also be Governors of provinces, and they mostly copied the writings of their predecessors, especially those of Dioscorides, who was probably the earliest botanist recorded in history. Some of his MSS. books

Britain. Some of these were cultivated by the monks in the grounds attached to monasteries for medicinal purposes, or as pot herbs; and, strange to say, many of these plants are still to be found, more or less naturalised, near these places, or where they formerly existed.

From these small beginnings, the monks soon planted vegetables and fruit trees, which were looked after by the inmates of those places. The knowledge of the use and culture of these plants soon spread to the people of the neighbouring cottages, and were grown by them. The most ornamental plants were cultivated also for their beauty, but as our subject is concerned with botanic gardens, we must leave the history of gardening to the interesting writer of the articles entitled "Old-time Gardening," which are appearing in this journal.

While ordinary gardens are concerned with the use and beauty of plants only, or in the case of public parks and recreation grounds for showing individual plants, or the massing of them for effect, the botanic garden has for its primary aim the promotion of botanical science, by collecting as many plants as possible from all parts of the world, and finding means for their proper growth, such as plant houses, warm water tanks, rockeries, and, in many cases, by supplying special kinds of soil, as peat, limestone, clayey soil, sandy soil, or sea sand for them. So far as possible plants that are allied should be planted near each other to show their relationship; or they are sometimes grouped together according to their uses, structure, or geographical distribution.

Botanic gardens, or as they were formerly called, physic gardens, are of comparatively modern origin, and, like the science itself, owes their birth to the needs of pharmacy. Thus, at the earliest European school of medicine, that of Salerno, in Italy, we find a record, in 1309, of the medical garden of Matthæus Sylvaticus; while in 1333 a similar garden was established by the Republic of Venice. Many similar gardens, public and private, were established in the next three hundred years. The first three public botanic gardens of which we have records were established in Italy; the first of these at Padua in 1533, that of Pisa soon followed, and that of Bologna, established in 1547 by Luca Ghini, that he might grow the plants required for teaching purposes. Luca Ghini was also the first public professor of botany.

I will now give the dates when some of the principal botanic gardens were established:—Zurich, in Switzerland, 1560; Paris, 1570; Leyden, 1577; Leipsic, 1580; Montpellier, 1598; Copenhagen, 1600; Jena, 1628; Oxford, 1632; Chelsea Physic Garden, 1673; Edinburgh, 1680; Kew, 1760; Cambridge, 1763; Trinity College, Dublin, 1786; Glasnevin, 1798; Liverpool, 1803; Ceylon, 1811; Belfast, 1830; St. Andrews University, 1889; Yorkshire College, Leeds, 1896; and Aberdeen, 1899.

The Paris Botanic Garden was founded in 1570 (or 1597?); but at first it is said only with the petty aim of varying the bouquets worn at

Court. In 1626, however, its scientific purposes were defined, and in 1635 professorships of botany and pharmacology were founded, which soon made it famous as the Jardin des Plantes. A further impetus was given by the popularisation of botany in the eighteenth century by the great Linnæus.—ALBERT HOSKING. (To be concluded.)

### BUDDLEIA VARIABILIS var. VEITCHIANA.

This new variety was exhibited by Messrs. J. Veitch and Sons (Limited), Royal Exotic Nursery, Chelsea, S.W., on August 18, before the Floral Committee of the Royal Horticultural Society, when a First Class Certificate was accorded. The dense thyrsoid inflorescence is coloured bright heliotrope, being quite 3in through at the base, and 12in to 15in long. Our illustration depicts the variety a little over half natural size. It is a very handsome new Buddleia.

**Buddleia variabilis var. Veitchiana.**  
(Half-size.)

are still in existence, the most celebrated of these being in the Imperial Library of Vienna, and from which plates were prepared, but two impressions only appear to have been taken off. One of these was sent to Linnæus, and is now in the library of the Linnæan Society of London, and the other to Sibthorp (either as a loan or gift), who was at Oxford in his preparation of the Flora of Greece, and that copy is now in the library of the Botanic Garden, Oxford.

Throughout the Bible we read of vineyards and gardens, so that gardening is very ancient. The Arabs were great physicians, and much versed in the medical properties of plants, which knowledge soon spread to Greece and Italy and other countries bordering on the Mediterranean, and gradually spread northwards to France, Germany, and Holland, and finally reached this country. Many of our cultivated plants, and some of the weeds of our hedgerows, were brought by the Romans when they invaded Great

### Some Pillar Roses.

Of the Waltham and other climbers I promised to say a word or two. They are well worth a place. No. 1 produces some beautiful blooms of good shape, but not very many of them. No. 3 is similar, but the flowers are darker, and the leaves are a beautiful purple colour in the spring. It does not grow quite so strong as No. 1. Madame Alfred Carrière is a good white, a very free grower, producing beautiful blooms, which are large and very fragrant. It does not flower as freely as do many of the Noisettes.

A Rose somewhat similar is La Biche. The blooms, which are pinky-white, are not so large. The flowering shoots are pendulous, which gives the plant a graceful appearance. Céline Forestier, an old Rose, but a very good one, a pale yellow, a free bloomer, and very hardy. This is an old favourite of mine, being the first climbing Rose that I had to attend to. It was trained over a wooden trellis against a high wall, and produced a large quantity of its beautiful blooms.

Euphrosyne, the pink rambler, produces clusters of small flowers, but they do not last very long. The plant does not grow so strong as its crimson rival, and does not favourably compare with that Rosa. I think the same may be said in respect to Aglaia, the yellow rambler, and Uralia, the white rambler, although I have not grown the two latter.

Rêve d'Or is a strong growing Noisette, producing very nice shaped buds and glossy foliage. It makes a good pillar Rose. In William Allen Richardson we have a general favourite, the colour, orange-yellow, and the size of the flower, making it an ideal buttonhole variety. It is more grown upon walls perhaps than pillars or arches; but it is also suitable for the latter purpose as well. Amongst single flowered section, Paul's Carmine Pillar is one of the best. It is very hardy, a strong grower, and produces beautiful blooms of a bright rosy carmine. The foliage is bright and clean, and, under liberal treatment, strong shoots are annually produced. Unfortunately the flowering period is short, but its other good points will make up for this. It is worth a place in all collections of pillar Roses.

A good companion to this is Paul's Single White. The flowers are large, white, produced rather freely, and remains in bloom much longer than Carmine Pillar. Its habit, however, is not so good. The Ayrshire Roses also make suitable pillar Roses. They are all very hardy and free bloomers; the flowers are produced in large clusters. Bennett's Seedling is a small double white; Dundee Rambler, semi-double white, with pink edges; Splendens has larger flowers of a flesh colour; Ruga is similar, with paler coloured flowers. These are all good varieties. This list does not by any means exhaust the number of Roses that may be used for pillar work. Those enumerated will generally be found satisfactory, and may safely be given a trial.—J. S. U.

### Nursery Specialities.

In extensive nurseries one expects, and often can find almost anything that may be wanted in the matter of plants; yet while this is true, specialities of some kind is now made the staple of most business houses in these days of progress and keen competition. In the neighbourhood of Bristol, namely, Westbury-on-Trym, Messrs. Isaac House and Son have familiarised their name by their association with Violets, Sweet Peas, and herbaceous plants, Polyanthus, and Violas. Being much interested in this sphere of horticulture, and having seen some of the fine displays made by Messrs. House, I made a point recently of calling on them to see this "home of flowers," a term aptly descriptive of their nursery.

Of Violets the present is not perhaps a time when much may be said, except that a great variety—indeed, all the most deserving and best among old and modern kinds—are represented in varying stages of growth, and in numbers amounting to something like 40,000 plants. Some new

houses are erected for planting a good number of the double flowered kind, and which it is said answers the purpose admirably. The structures are of the usual ridge and furrow type, with open sides admitting a current of air passing through the whole width, and abundant provision is also made for roof ventilation. The beds are raised so that the plants obtain a maximum of light and air, without which they could not succeed in winter.

Pentstemons and Phloxes gave the greatest wealth of colour at the time of my visit, and these were indeed fine, both in plant, colour, and variety. For grouping in beds or as isolated plants in the front of herbaceous borders, these Pentstemons would be a telling flower for the late summer and autumn months. The spikes are robust, and the individual bells of immense size, while the colours are both varied and striking. A few of the best are Miss Wilmott, Jean Mace, Jane Misme, Dragoon, Gabriel Barde, Andre Lebon, Commandant Larmy, Capt. Marchand, Dr. Chantelesse, Lady Brodie, Lord Lister, Phryne, Talma, and President Carnot. These were hosts of others, but no useful purpose would be served in repeating names.

Perennial Phloxes were grand in colour and truss; the best were W. Robinson, Pantheon, Miss Pemberton, Matilda Seras, Lord Rayleigh, Le Cicle, Fiancée, Etna, Coquilicot, Brilliant, Albatre, Adonis, and Cœur de Lyon. Two seedling whites of Messrs. House's own raising are of great beauty and dwarf habit, named respectively Esme and Viola.

Delphiniums are another speciality occupying much space, and affording an agreeable change and contrast to the bright colours of the Phloxes. Here again are much variation of colour, but the finest of all is Persimmon, a new and very striking flower. Belladonna is another lovely variety, sky-blue in colour, with a free branching habit. Of dark colours, W. B. Child, King of Delphiniums, Sir J. Forest, and Sir Walter Scott were noted as being extra good.

Chrysanthemums, maximum and latifolium varieties, are represented in almost bewildering numbers, varying not in colour, but very much in character of flower and habit of growth. Li Hung Chang and Shasta are two of the most recent introductions, being remarkable for their individual size. Margaret Marwood is a dwarf growing kind, and perhaps the freest blooming plant in the whole collection. Laciniata, Robinsoniana, Mikado, W. H. Gabb, Snowflake, Countess Cadogan, Grandiflora, Triumph, and Magnificum are some extra fine.

Pyrethrums and Gaillardias are in much demand, and a supply of plants would appear to be grown to meet it, and the numbers of these in variety are almost endless. Michaelmas Daisies (Asters) are represented by no less than 120 kinds. Polyanthus and Primroses, double and single, are grown and flowered by thousands, as well as other rare species and varieties, including the curious Hose-in-Hose and Jack-in-the-Green.

Sweet Peas, which are grown for the dual purpose of exhibition and seed production, Messrs. House have given ample demonstration of their scope to deal with, and their skill as cultivators. Their exhibits have been remarkable for refinement and clearness of colour.

About 100 varieties of Fancy Pansies are grown, and a great number of Violas, which, judging by the vigorous growth and wealth of flower, find a congenial home here. Carnations and Pinks are other specialities for which a good demand exists, and in these, as with other flowers, the Messrs. House devote time and study in obtaining improvements of their own by hybridising. A fine yellow border Carnation named Huntsworth is a good non-splitting, clear coloured flower that should have a future before it, and particularly as good yellows are by no means numerous.

Besides the foregoing specialities in flowers there are a widely differing assortment of herbaceous plants suitable for border planting and cut flower purposes. Chrysanthemums, too, of the early outdoor section are represented by the best and most select, particularly of those bearing large flowers. Rock and Alpine plants are numerous, such as Sempervivums, Saxifrages, Sedums, Aubrietias, Silenes, Veronicas, Phloxes, double flowered Arabis, and Rock Roses. These are a few among the many varieties adapted to this interesting phase of garden work. Much more might be written of the interesting things to be found in this rural nursery, but sufficient has been said to show that popular flowers are those favoured by the Messrs. House.—W. S.

POMPON CHRYSANTHEMUMS. (See page 378.)

### Newton Wonder Apple in Kent.

I notice that in a reference to this fine Apple it is stated that it does not succeed in Kent. [The reference should have been better qualified.—Ed.] Newton Wonder succeeds admirably. I know many instances in which it is represented, and growers generally speak highly of it. Mr. Bunyard, Maidstone, in his catalogue speaks of it as being "One of the best among recent sorts," and he would not be likely to do so unless it succeeded in Kent. Some of the best examples I know grow in the somewhat retentive soil in the Weald of Kent, and I can hardly believe that Newton Wonder could possibly succeed better than it does there.—G. H. H.

### The Gardener's Position.

Changes everywhere! Nature herself is now preparing to put on her winter garb, changes in gardens, change of master, change of man, horticulture generally undergoing an upheaval, causing some to doubt if the private gardener in the future will really exist! Still, on the whole, the trend of things is towards a higher standard—greater cultural skill shown, in spite of croakers of the old school, better taste exhibited in the discernment of form and colour, and, it must be admitted, too, a better class of men employed generally in the sphere of gardening. To many it brings a note of sadness, as all changes usually do—sad, because the brightness of summer has faded, and the winter of the future for them, although buoyed with hope, is full of uncertainty and apprehension. It is very questionable if the life of the gardener of to-day, in spite of his immense advantages over his predecessors in ways and means, is cast in as pleasant lines as was their's. The hurrying, scurrying, irritable spirit of the age is as much a reality to him, although far removed from populous centres, as it is to the toiler in the great cities. True, he has that around him to delight both ear and eye, which the latter has not, but the petty annoyances and indignities to which the average gardener is subjected, and which appear inseparable from domestic service, and which, unlike the artisan or trade grower, he cannot resent; coupled with the precariousness of his position, and the possibility of being out of permanent employment for several years, more than overbalance the fact that he is not a pecuniary loser by a bad or indifferent season. Had he to face the question of profit and loss in addition, his life, indeed, would not be worth living.

Undoubtedly, there are employers who look on their domestic servants as human beings and fellow-men, and not just simply instruments to minister to their pleasure; but those best acquainted with service know that, although the feudal system no longer exists, the spirit of it is as rampant as ever. As "G. H. H.," page 349, pointed out last week, the gardener is not a "unit in combination to accumulate wealth;" therefore, is not entitled to fair treatment. It is only the man who acquires wealth, or who can place money, the spending of which he is entrusted with, in other's hands, who is entitled to any consideration whatever from any quarter. It would be absurd to expect anything different. If a man can neither spend, for lack of possession, nor dispense money, for the reason that he does not happen to be entrusted with any, what earthly good can he be?

So argue our smart business men, and undoubtedly right, too, from their point of view. Can we expect that, with the advent of the woman-gardener, who, we are told, has come to stay, if not actually usurp the "mere man" gardener, matters will improve in this respect? Probably we may find that, in addition to horticulture, she will be giving her wealthier sister, in whose employ she may happen to be successful, lessons in those qualities of heart which go to make up a lady.

Many an unfortunate male practitioner, forgetful of all usurpation, will here exclaim: "Alas! might these things be!"

The boys of the bothy, too, are anxious to know more of the general drift and ultimate position of the lady gardener, and to know as well "where they will come in" if "mixed" bothies are to be a feature of the gardening of the future; but to a suggestion that the associations of such might improve their manners, proclaimed, in professional pride, that their's were above reproach, and to another, respecting the advisability of developing their power of observation, said it wasn't their fault if the whereabouts of the boss was unknown to them!—G.

### Perpetual Fruiting Strawberries.

I have been anxiously waiting for a further report on the above from "W. R. Raillem," and am glad he has gone back to his old love St. Joseph. I think that attention is much better placed on St. Joseph than on St. Antoine de Padoue, which is found to be a poor cropper, and has coarse-looking fruit, and wanting in flavour in my district of Lincolnshire. I was induced through "W. R. Raillem's" first article, recommending St. Joseph, to try it, and find it a continuous and good cropper, of fair quality, and of medium size. At the present time (October 17) there is a good crop in various stages in bloom, also green and ripe fruit. It may interest "W. R. Raillem" to know I have anticipated his suggestion, and have raised a number of seedling St. Josephs, and consider some of them are improved forms, having larger and better shaped fruit. I have other seedlings, not St. Josephs, which are now producing fruit freely in the open.—W.

### Gardeners' Education.

As a young gardener, it is with great interest that I devote a few moments weekly to follow the opinions of a few of my brother horticulturists respecting the already "much-worn" subject of the young gardeners' education. I venture to ask: Which of the worthy chiefs are we young gardeners to follow? He who preaches Shakespeare and university education with a loud voice, and passes over such small items as the proper use of the spade and grape-scissors; or he to whom these "small items" are indispensable, as the only sure basis of a source wherewith to obtain young yet perfectly capable fellows, in whom the love of their profession is their first thought when dawn breaks, and not unseldom their last in the evening? This leaves little or no room for studying the immortal Shakespeare. Each would, and, in fact, does score in their own way, for do we not hear on the one hand: "Splendidly educated that young fellow is, you know, but he's not worth his salt." "Why?" "He can't thin me a bunch of grapes." And, vice versa: "That fellow is worth his weight in gold, but (and this is added, as it should be, reluctantly) his manner, especially when addressing his superiors, is, to say the least of it, a little below that standard of efficiency which to the twentieth century gardener is indispensable."—H. T.

### Gardening Panaceas.

We find that credulity is not unknown in the courts of horticulture. Every gardener is well aware of the many cure-alls which presume themselves upon his notice. They are not, perhaps, legion, but still they come, and it is very questionable what they will not be before the present century is completed. Like the vendor of pills, tinctures, and syrups, the vendor of plant medicine has in his ample cornucopia an antidote for all the ills of plant "flesh." Of course, the wise gardener will be on the alert for the many-sided man, and safeguard against his intrusion into his province. Unfortunately, however, gardening has proved a somewhat lucrative field for the operations of the panaceist. This is to be regretted, because of the superior tone of common sense, as well as intelligence, that marks the character of the average gardener. Though the mountebank, when he disposes his vapoury wares among a credulous people, in a measure encroaches on the province of the regular practitioner of medicine, he does not necessarily interfere with the medical man's reputation. It is not so clear that the same can be vouched as a plea for the gardener who has come under the spell of the panaceist. The medical man and the quack, it is true, are rivals—competing, as it were, in the same arena, and the dupes of the latter are those to whom very often both administer. The consequence of the labours of both may or may not be referred to either.

There is no such breakwater of irresponsibility to safeguard the reputation of the gardener. He alone becomes directly responsible for the impositions of the panaceist. If he makes a plunge for one or all of the multifarious nostrums for the benefit of plant life, and finds that a dose of common sense and fresh water would just as well suit the cases of nine-tenths of his patients, he surely must feel that his reputation is not on the up grade. We never thought much of the gardener who depends too much on the virtues of his bottles. Indeed, the man who uses them to any extent is perhaps scarcely worthy of the dignity of gardener. In our own experience we cannot say with sincerity that we ever yet came in contact with a plant remedy that invariably fulfilled the prescribed claims. We know only one specific remedy for plant ills—and it covers a very few—and that remedy is sulphur. Cleanliness and plenty of fresh air where possible are the best and only curative and preventive agencies to cope with disease; and, of course, when these are neglected, and a pestilence of mealy bug breaks out in a house, the cure then, be assured, is the agency of fire.—D. C.

## Ornamental Plants and Shrubs.

In the course of the lecture which he delivered at a recent garden party at Messrs. Pennick's nurseries, near Delgany, in the County Wicklow, Mr. A. D. Richardson dealt at considerable length with the employment of shrubs of various kinds for ornamental planting, and specially referred to the extent to which these might be availed of in setting off private grounds and homesteads. In his own experience he had found, he said, no group of plants so generally useful to the landscape gardener than hardy shrubs, whether evergreen or deciduous, and what with discoveries within recent years of new species, and the production of new forms by the cultivators and hybridisers, the gardener now had no lack of suitable material at his command. Still, he thought that the resources which planters possessed in this way were not utilised as fully as they might be—generally speaking. There was a great tendency to “ring the changes,” so to speak, on a few species and varieties, but there were not wanting at the same time signs of a good deal of change of taste in this respect, thanks to the influence of the horticultural press, through whose agency so many fine flowering shrubs have been brought to the notice of planters.

In the grouping of shrubs for effect in landscape and ornamental planting no hard and fast rule could be laid down. Hitherto the great mistakes made in this direction have principally taken the form of the employment of too few varieties of shrubs. By this he did not mean that too few kinds had been used in each individual instance, but rather that there had been too much repetition of the same kinds in every case. Yews, Hollies, and a few others often formed almost the stock-in-trade of some planters, while the fine flowering shrubs were conspicuous by their absence. Now, while no one can object to the judicious use of these plants, when they are employed too exclusively they produce a feeling of monotony or sameness in the different parts of a place, or in different places.

Again, too free use has often been made of the common evergreens. In small places where there is little scope for planting in large breadths evergreens must be largely employed, both for shelter and to produce seclusion; but in the case of large places there is no necessity for this. In smoky towns, too, some kinds of evergreens are too freely used. The evergreen character of a plant is due to its power to retain its leaves until the next crop has been produced, or longer. In some cases, as for example in the case of the common Ivy, the leaves are retained only until the leaves of the following year are produced, when they drop. In other cases, as in those of the Yew, the leaves persist over a number of years. Now, it is quite evident that shrubs which retain their leaves for a number of years must, in smoky towns, become very grimy and unhealthy, and consequently they look unsightly. Deciduous shrubs, or those which retain their foliage only for a year, have, on the other hand, a much more healthy and fresh appearance.

In town planting, where the air is loaded with impurities, great care requires, therefore, to be exercised in the selection of evergreen shrubs, and it is a great mistake to employ Conifers to any extent. This is, of course, a rule which cannot be rigidly applied, for, as we know, there are shrubs and trees of all kinds which won't tolerate a polluted town atmosphere. In the open country, where the air is pure, it is, of course, quite different, and there evergreens may be used as circumstances demand with the certainty that they will always be fresh looking, provided, of course, that the conditions as to soil, exposure and so forth, are suitable.

A great deal more might yet be done in the planting of fine flowering shrubs, both evergreen and deciduous. Of these we have now a great wealth, and a great proportion of them are sufficiently hardy for planting almost anywhere in the British Isles. But to show off fine flowering shrubs, at any rate of the larger kinds, to advantage, there is no better way than by planting either singly as specimen plants, or in groups of one kind. In such positions they develop in a perfectly natural manner, and they never require to be cut or pruned into shape; in fact, such a thing means mutilation when it is carried out systematically and vigorously.

Fine flowering shrubs grown in this way, and simply left alone, are far prettier and far more effective in ornamental grounds than when grown in any other way. But take, for example, the Rocky Mountain Bramble (*Rubus deliciosus*), a plant which does not seem to be very plentiful, but one

which has a great deal to commend it to lovers of flowering shrubs. What could possibly be finer than this plant grown in this way when covered with its large white Rose-like flowers? Or, again, take *Spiræa discolor* (better known, perhaps, as *S. Ariaefolia*). Grown in this way, few shrubs are more graceful or more effective. A large number of fine flowering shrubs, both deciduous and evergreens, lend themselves to this kind of treatment. Among them the following may be mentioned as worthy of attention:—

*Berberis Darwini*.  
*Genista aetnensis*.  
*Cytisus albus*.  
    *scoparius Andreanus*.  
*Caragana melauocalyx*.  
*Prunus triloba*.  
*Spiræa bella*.  
    *discolor*.  
    *Lindleyana*.  
    *Van Houttei*.  
Roses—*Lord Penzance's Briers*.  
    *rugosa*.  
    *pinpinellæfolia altaica*  
    and others.  
*Pyrus floribunda*.  
    *japonica*.  
*Amelanchier canadensis*.  
*Deutzia crenata fl.-pl.*  
*Philadelphus grandiflorus* and varieties.  
*Hamamelis arborea*.  
*Viburnum Opulus sterile*.

*Ribes aureum*.  
    *sanguineum* vars.  
    *Gordonianum*.  
    *speciosum*.  
*Diervilla florida* and varieties.  
*Olearia Haasti*.  
*Forsythia suspensa*.  
*Andromeda (Pieris) floribunda*.  
*Syringa chinensis*.  
*Ligustrum ibota*.  
*Buddleia globosa*.  
*Rhododendron cinnabarinum*.  
    *Thomsoni*.  
    *Catawbiense*.  
    *Nobleanum*.  
    *White Nobleanum*.  
    and of hybrids.  
    *Jacksoni*.  
    *Cynthia*.  
    *Empress Eugénie*.  
    *The Queen, &c.*

These are a few of the larger kinds, but they by no means exhaust the list. Of the smaller kinds many may be used for massing in certain sites, and there are also many genera to select from, such as *Cytisus*, *Cistus*, *Genista*, *Hypericum*, *Jamesia*, *Philadelphus* (Lemoine's hybrids and microphylla), *Skimmia*, *Spiræa*, *Tamarix*, *Andromeda*, *Calluna*, *Erica*, *Bryanthus*, *Ledum*, *Leucothoe*, *Rhododendron*, and *Veronica*. This is not, of course, the only way in which these plants should be grown. They may be used in a great variety of ways, but when isolated they show to much greater advantage than when in mixture with other kinds where, as in a plantation of forest trees, the struggle for existence setting in sooner or later, and the suppression of the weaker brought about.

There is another kind of shrub which is of great utility in ornamental planting, viz., the “rambling” or climbing shrub. It often happens that unsightly objects which cannot be cleared away have to be covered up by some means, and in such cases shrubs of this kind are invaluable. Some of them are very showy flowered, others have fine foliage. Among the ramblers may be placed first *Rosa multiflora*, and its form *Crimson Rambler*, perhaps the finest rambling Rose which has ever been produced. Then there are the double flowered brambles, *Vitis Coignetia*, a magnificent Japanese Vine which produces very large foliage, which takes on a beautiful purplish red tint in autumn; *Clematis montana*, a beautiful early flowering sp.; the Honeysuckles, yellow Jasmine, *Vincas*, and so forth. Then of those which attach themselves by root-like supports we have, of course, the Ivies, *Ampelopsis*, and, perhaps, the most tenacious of all, *Hydrangea petiolaris*. The following can be recommended as suitable for the various positions specified:—

### PLANTS SUITABLE FOR ROCKWORK.

Heaths and Ericas.  
*Bryanthus, erectus* and *empestriformis*.  
Dwarf *Rhododendrons* and  
    *Azalea amoena*.  
*Andromedas*.  
*Thuja aurea* and *elegantissima*.  
Bamboos (dwarf).  
*Cotoneaster horizontalis*  
    *thymifolia*.

*Daphne blagnayanum*.  
*Gaultheria procumbens*.  
Dwarf *Genistas*.  
Dwarf *Junipers*.  
*Lithospermum fruticosum*.  
*Pentstemon Menziesi*.  
*Polygala Chamæbuxus*.  
*Spiræas* (dwarf).  
*Veronicas* (shrubby, New Zealand).

### AUTUMN, WINTER AND SPRING FLOWERING SHRUBS.

*Hydrangea*.  
*Hypericum*.  
*Rhus*.  
*Jasminum*.  
*Daphne*.  
*Forsythia*.  
*Nuttallia*.  
*Calythanthus*.  
*Erica carnea*.  
*Magnolia conspicua* and others.  
*Hamamelis*.  
*Cytisus præcox* and *albus*.  
*Pyrus Cydonia*.  
*Prunus triloba*.

*Ribes sanguineum*.  
    *Gordianum*.  
    *aureum*.  
*Ledum palustre*.  
*Rhododendron præcox*.  
    *ciliatum*.  
    *dauricum*.  
    *Nobleanum*.  
    *Thomsoni*.  
    *Cunninghami*.  
    *Campanulatum*.  
    *Caucasicum*.  
    *Jacksoni*.  
    *Rhodora*.

### Chrysanthemums in London.

Two *Chrysanthemum* shows under the control of the London County Council opened on the 15th at Battersea and Finsbury Parks, and will remain open to the public for some weeks.

## Gardening at Wistow Hall.

Some gardeners are specialists, and they achieve success by growing a few things superlatively well; others have no specialities, but grow everything under their charge creditably; and a third, and very limited section, seem to possess the gift of branding everything they grow with the mark of a master hand. Mr. F. Clark, of Wistow Hall Gardens, near Leicester, seems to belong to the latter section. At least, that was the impression conveyed to me by a recent visit to the gardens he controls.

The Sweet Peas from Wistow have often been described during the past season, as they have won high honours at the principal shows. I can well understand this when I saw the plants, for although the flowering period was practically over the grand growth still remained. The clump system of culture is adopted. These are planted a yard apart, and each contains five plants. One would think from appearances that there were twenty plants to each clump judging by the great number of grand strong growths, in many cases 12ft in height.

In the kitchen garden splendid produce met the eye at every turn. The Celery was large, strong, and healthy, and ready for the final earthing. Leeks showed great promise, zine tubes having been used during the process of earthing. Two fine rows of Peas proclaimed how difficult it is to find a better variety than Autoerat when it is well grown. Brussels Sprouts were giants for size and sturdiness, and showed great promise of fine results in the near future.

The glory of the kitchen garden at the time of my visit—September 18—seemed to be a magnificent lot of Ailsa Craig Onions. These had been uprooted a few days, and were lying in full sunshine to ripen, precautions being taken to turn them over every day or two. I should not like to hazard a conjecture as to the weight of the individual bulbs, but collectively they were certainly the finest lot I have seen grown in a similar space. Trenching the land three spits deep very year, and using a very liberal allowance of farmyard manure, are the main cultural practices upon which Mr. Clark builds his success; and, indeed, deeply working the soil has produced a striking effect upon the produce of the whole garden.

In the vineries were many large, handsome bunches of Madresfield Court Grapes; perfectly "finished" Muscats in the same house were also large and shapely in bunch, only wanting a little more of the amber tint [which has been so seldom seen this season.—ED.] to make them perfect. Considering, however, that they have been grown in a house where Madresfield has coloured splendidly, this must be regarded as a fine achievement in Grape growing, as Muscats require much more heat than the popular black Grape above mentioned. I noticed several standard Apple trees carrying very fine crops, as a result of judicious thinning of the branches and root-pruning.

Chrysanthemums are now claiming a large share of attention. The plants are taller than usual, but look particularly strong and healthy, and as they have had full exposure, the wood should be well ripened. The vagaries of the season have had a somewhat peculiar effect upon some varieties, which were stopped when about 9in in height. From that point they have grown continuously without having made a break or a bud until the beginning or middle of September. Mark Firth, Esq., and Mrs. Firth have every reason to be proud of the fine condition of their gardens, and of the achievements of their gardener.—H. D.

## Gadding and Gathering.

Messrs. Bull and Sons, Chelsea.

The establishment of Messrs. Bull and Sons, at 536, King's Road, Chelsea, is mainly reputed for novelties and rarities in tropical exotic plants, and the collection is worthy of anyone's time to go and inspect; but, besides new or lesser known stove plants, one may also mention hybrid Orchids, in considerable variety and numbers, Bromeliads, economic plants, and especially Fuehsias and Zonal Pelargoniums, each of which form important sections of the firm's trade. Probably no other nursery contains the same variety of economic plants—plants cultivated on an agricultural scale in one part of the globe or another for the food supply of mankind, such as Cacao (or Cocoa, as we English wrongly name it), Coffea, Chinchona, Anonas, many rubber-yielding plants like *Hovea braziliensis*, *Kieksia elastica*, and Castilios, and other tropical genera needless to detail.

The present notes are descriptive of a very few meritorious plants, which someone, with an interest in tropical and temperate exotics, may find useful. The beautiful *Cestrum elegans*, with clusters of bead-like pink flowers, is an admirable pillar plant for a temperate range or corridor; perhaps the yellow or orange *Cestrum*—*C. aurantiaca*—is less familiar in gardens than *C. elegans*, and, moreover, the generic name *Habrothamnus* is more generally employed than that of *Cestrum*. By frequent syringings with warm, soapy water, these very beautiful plants can be kept quite clean. A new comer in the line of "foliage plants"

is found in *Dianella tasmaniana* variegata, which may most fittingly be described as a pigmy representative of the New Zealand Flax (*Phormium*). The sideways manner of growth is a character, as also the flat, blade-like leaves, which are of the same consistency as those of the *Phormium*, and far more deeply and beautifully variegated with orange-yellow.

Another variegated plant is *Tradescantia regina*. It is larger in growth and general character than those usually seen in gardens, colouring most brilliantly and well defined. For the edge of stages or on rockeries indoors this handsome and easily-grown plant commends itself. As a hall plant, where cold draughts are excluded, the very elegant *Jaearanda elegantissima* merits a place, and I am not acquainted with a more suitable decorative plant, which is at once so serviceable and elegant for this purpose.

A note must be spared for the following subjects with coloured foliage, namely, *Begonia President Boureuilles*, a larger and more effective foliage-Begonia than *B. margaritacea*, the well-known purple-coloured stove species. In *B. President Boureuilles* there is a shimmering metallic lustre over the very deep purple-red, and a noble plant it makes. *Draeena* (or *Cordyline*) *terminalis* is much grown, but the variety *Mayi* is superior as a colouring plant, and seems also neater in habit. Messrs. Bull have some shapely samples in 5in and 6in pots. *Maranta picta*, *M. insignis* (new), and *Panax Victoriae* are stove plants of exceeding beauty, and all introduced by the firm. *Croton Reedi* and *Draeena Victoria* are irreproachable, and the latter is unexcelled for winter use as a golden variegated and large-leaved decorative plant.

*Polypodium ericoides ramo-eristatum* is a Fern of dwarf stubby growth, much incised and crested at the tips of the fronds. *Platynerium Veitchii* furnishes one of the most elegant of the Elk's-horn Ferns, the drooping segments of the stems being covered with a silvery-grey pile of fine hairs. *Licula Muelleri* resembles *Rhapis flaxelliformis*; *Aralia triloba* is a South Sea "islander," deserving a paragraph all to itself; *Polypodium conjugatum*, an entirely new and distinct species, which will assuredly make its way to many collections; *Asplenium marginatum*, very pale green in colour, with handsome fronds of tender structure; and lastly, for the present, *Eugenia myriophyllum*, a graceful, shrubby little novelty, with abundance of dark green linear leaves, are each worthy of attention.—WANDERING WILLIE.

## DOCHFUR, INVERNESS.

Dochfour, the property of J. E. B. Baillie, Esq., lies five miles N.W. of Inverness, on the north side of Loch Dochfour. The gardens and grounds stretch along the loch in a strip about half a mile long, by one-third of a mile wide, lying between the loch and the hill. Being on a slope, they are terraced round the house and for the croquet lawn and Italian garden, the rest following the natural slope of the ground. The garden is sheltered from the north and east by the hill, lying in the loch, which is never frozen, the climate being remarkably mild—14deg. was the hardest frost last winter—and shrubs and plants will grow with very little protection, though they will not succeed in the Midlands in England. The west front of the house is covered with *Ceanothus Gloire de Versailles*, and the gardener's cottage has *Magnolias*, *Choisya ternata*, and *Azara* growing on it and flourishing, with but a slight protection of spruce branches in winter.

The terrace is planted with *Cannas* in variety, *Gladiolus*, fibrous rooted *Begonias*, and *Pelargoniums*, all of which do well. The vases were last summer alternately filled with *Cannas* and variegated New Zealand Flax, and the general effect was wonderfully good and sub-tropical. There is a very good and well grown collection of Conifers, said at one time to be the most complete in Scotland. It has of late years got a little out of date, but Mr. Baillie is planting largely, and the young trees promise well. An orchard was planted last autumn, on the model of those in Kent and Surrey, and looks well. There is a good, though not large, kitchen garden, the borders of the different plots being fenced with espaliers, and planted with a good collection of herbaceous plants.—J. T.

## PEAR, MICHAELMAS NELIS.

Our illustration of this Pear on the opposite page defines its natural size and form. The skin is thin, firm, of a bright greenish yellow, with minute brownish specks. Eye prominent, level with the rounded top of the fruit; the segments remaining distinct and generally evenly outlined. Stalk long, narrow, somewhat curving. Flesh pale tea-coloured, very juicy, melting, and richly flavoured. The tree is a free grower and bearer, and was introduced to commerce in 1901 by Messrs. George Bunyard and Co., the Royal Nurseries, Maidstone, who found it by chance in a cottager's garden. It is a seedling from the well-known Winter Nelis. An Award of Merit was given to it on October 7, 1902. It succeeds best grafted on the Quince, and is in use during September and October.

## Possibilities of the Australian Fruit Trade.

Apples of excellent flavour and of enormous size grow to perfection in several of the States of Australia. Indeed, there are districts in most of them, in which attention might most profitably be directed to fruit culture. Till very lately Australia has been the very ideal of a happy-go-lucky land. Gold has laid on the surface, flocks of herds have increased and multiplied, and the earth has yielded her increase so lavishly that the colonist has grown to think that his responsibilities were limited to a very casual planting, leaving to Providence the watering and general supervision of his crop, as well as the final increase. The writer has seen the banks of a river bordered all along with Peach trees, which have planted themselves from the fallen fruit, without any attention. Those Peaches which the pigs could not reach, or shake down, were packed in boxes and sent to the towns. Only quite lately have the several Governments awakened to the fact that some little knowledge is desirable in agriculture, and experts have been engaged to travel through the States and instruct the settlers how to obtain the best returns from their crops.

Fruit culture has, until lately, received much less attention than its importance has merited. Imprimis there was the difficulty of obtaining suitable land near the large towns, and in a new country means of transit were necessarily expensive and inadequate, thus much of the most perishable fruit reached the market in unsaleable condition. Again, no discrimination was exercised in the selection of varieties of trees suited to the conditions, climatic and topographical, or to the taste of the consumers, and little care was exercised in picking or classifying the fruit, still less in packing. Experts are well aware that different varieties of Apples and other fruits ripen in varying ratio, and such should be separately classified and packed, otherwise those which ripen more quickly will over-ripen and deteriorate the rest. Another frequent error has been that fruit has not been allowed to cool for sufficient time to get rid of the heat absorbed, and thus when packed in cases the warmth evolved has adversely affected the fruit and ripened it too quickly. Cuttings of fruit have been carelessly imported from Europe and America, which contained insect pests. In the congenial climate, and with the fecundity which characterises all animal life in Australia, these multiplied so rapidly that whole orchards were destroyed, and in one noted fruit growing district of New England many orchardists were reduced to the verge of bankruptcy. Now,

the most stringent regulations are enforced in all the States against the importation of diseased fruits or scions. With the "lasser-aller" distinctive of the settler these drawbacks were sufficient to deter many from fruit growing.

At the present time conditions are entirely different. Experiments have demonstrated the best kinds of fruit to cultivate. The Victorian Acclimatisation Garden alone is said to have 700 varieties of Apples and 400 Pears; whilst 20,000 scions of fruit have been distributed annually to members. Till recently, also, the outlet for orchard produce has been limited to the inter-State supply, and the production

has so far exceeded the demand that jam factories and cider making have absorbed much of the fruit. Now that the White Star line, which has done so much for the development of Australia by cheap freight and passenger facilities, is running a regular service, with every appliance for the carriage of fruit, and the Alfred Holt line are also carrying regular consignments, Australia has an opening for a share in the fruit supply of the English market, which has an annual value of about £8,000,000.

With regard to the condition of the fruit sent to Liverpool by Tasmanian (and Australian) growers last April, of the seven thousand odd cases of Apples indented to Liverpool by the Medic, about one-third were by special request sent on to Liverpool from London by rail to catch the market. The fruit was in excellent condition and of fine flavour, and the prices, from 11s. to 14s., were considered very satisfactory. They were mostly rather small green varieties of Apples, and all, as remarked, from Tasmania. On the continent of Australia, many districts of New England, and the higher altitudes of Victoria and South Australia are admirably adapted for the growth of the finest dessert Apples. The soil is very rich, and the winter cold is sufficient to ensure the necessary time for the trees to remain dormant. Fruit,

grown with care on these ranges, will bear comparison with the best Canadian Apples. The mammoth fruit grown near Stanthorpe would be too large for export, as it would ripen unevenly; but Ribston Pippins, New York Pippins, Blenheim's, and "Alexandras," all popular varieties in England, could be cultivated with success and profit. Quinces, which grow luxuriantly in all the States, ought to carry well and yield a good return brought to Liverpool direct, as apparently few, and those of the poorest, are brought here.

With regard to Citrus fruits, Oranges, Limes, Cumquats, &c., our market is pretty well supplied from the Mediterranean and California; still the Oranges of Queensland are of remarkable size and quality, the Blood Oranges and Navel Oranges especially, and the long time over which the crops

A New Dessert Pear, described on page 386.

extend make experts think that they could be brought over when our supply is lightest. Consignments sent to Vancouver arrived in A1 condition, and fetched good prices, this proving their carrying quality. The Pears of Victoria and Tasmania are of fine flavour. The question of tropical fruits must await the perfection of the new process by which it is mooted that perishable fruits may yet come to be carried long distances without depreciation. Pines, Grapes, Mangoes, Peaches, Apricots, Nectarines, Persimmons, Guavas, Custard Apples, and the Pawpaw, whose medicinal virtues make it so valuable as a cure for cancer and dyspepsia, all grow in Queensland in abundance.

It may be suggested that the manufacture of the Guavas and Quinces into paste, the Mangoes into chutney, and the drying of Apricots, &c., might be profitable. Dried Apricots, Raisins, and Currants have been brought to great perfection at Mildura irrigation fruit farm. Whether they could be produced cheaply enough to stand the freight in competition with the home market would have to be considered. Dried Bananas packed in wooden boxes like figs have also been prepared. They are not appetising in appearance, but very palatable. At present the abolition of black labour will leave many acres of land hitherto under sugar lying open for other cultivation; but this would only be suitable for tropical crops. In Victoria, land suitable for fruit growing is, just at present, to be had for very little cost. The unsettled conditions owing to the unequal pressure of the Federal tariff on different States, which has produced a non-progressive state of things for the present, affords an admirable opportunity for obtaining land under easy conditions. The problem of systematic fruit culture on a large scale is, with the present freight facilities, well worth consideration.—LIVERPOOL JOURNAL OF COMMERCE.

## Societies.

### United Horticultural Benefit and Provident.

The annual dinner of this society was held last Thursday, the 16th inst., in the Throne Room of the Holborn Restaurant, London, when 111 persons partook of an excellent repast. Arthur W. Sutton, Esq., V.M.H., F.L.S., admirably officiated as chairman, and was supported by a number of the leaders in horticulture from in and around the metropolis. An exceedingly interesting musical programme and demonstration of thought-transmission, or *clairvoyance*, was greatly enjoyed, and a number of toasts were accorded. The loyal recognisances were heartily responded to, and the chairman was closely followed during his speech on behalf of the society and its aims. Our leader is this week devoted to a consideration of the society's position, and the statements therein contained present a capitulation of Mr. Sutton's words. It is most satisfactory to learn that £20,000 are now invested, making £20 per member. The officers of the society are working their hardest to secure the enrolment of members, both honorary and privileged, so that the total of the former may be raised to 100, and that of the latter to 1,000, before the close of the year. A strong appeal was made to gardeners north of the Tweed, "who know a good thing when they see it," to give this benefit society their earnest consideration. It is a benefit and provident society for gardeners, and worked and sustained absolutely by gardeners, and no similar society in the United Kingdom is so healthy or so substantial, nor can show an investment of £20 per member. The officers, one and all—Mr. Hudson, as treasurer; Mr. Collins, as secretary; Mr. C. H. Curtis, as chairman of committee; and Messrs. A. Hemsley, Geo. Kelf, T. Winter (vice-chairman), W. P. Thomson, W. Woods, C. F. Harding, H. Purless, E. Burge, W. Taylor, and A. Stanbridge, as members of that committee—are attentive and indefatigable in their several duties, and but for their application the present progress could not be sustained for a single week. Mr. W. Collins, 9, Martindale Road, Balham, S.W., is secretary.

### Binfield Horticultural.

The winter session of the above society commenced on October 14, when there was a very good attendance of members. A most interesting paper on "The Renovation of Old Fruit Trees" was read by Mr. Neve, of Lindlesham. The lecturer dwelt on the importance of keeping old fruit trees in good bearing, and described the method he had adopted with some espaliers, which when they first came under his charge, bore small, unuseable, cankered fruit. He had lopped off all the side branches and headed back the main stem, and thus produced a bush tree,

which, in the course of two or three years, furnished an ample supply of good fruit. This plan the lecturer advocated in preference to grafting when the trees were of good sorts. Manures and manuring, insect pests, head and root pruning, and other points were ably dealt with. The lecture was illustrated by photographs of the trees operated upon. An animated discussion followed, in which Messrs. Bungay (chairman), Paine (secretary), Howell, Busby, Mason, Galliford, and others took part. A hearty vote of thanks to Mr. Neve for his instructive paper closed the meeting.

### Ipswich Mutual Improvement.

On October 16 the second meeting of the current session was held in the Co-operative Hall, Mr. A. Sowman in the chair. A most interesting paper on "The Germination of a Seed" was read by Mr. A. Martinelli, of the Ipswich Scientific Society. By the aid of carefully prepared diagrams, the essayist traced the development of the seed from the impregnation of the ovules by the pollen grains, dealing successively with the formation of the embryo, of endosperm, starch, and other materials in seeds. He likewise referred to the conditions essential to germination, viz., heat, air, and moisture; also to the action of diastase in germinating seeds. An animated discussion, relating principally to the vitality of seeds, was participated in by Messrs. Morgan, Battram, Cotton, Chandler, A. Creek, Cavannagh, E. Creek, and the chairman. Mr. J. Battram, Oaklands Gardens, exhibited a dozen good bunches of Michaelmas Daisies, principally of the lighter kinds. A nice bunch of Lily of the Valley from retarded crowns was shown by Mr. W. Close, Holy Wells Gardens.—E. C.

### Liverpool Fruit and Root Show.

This show, which was opened by the Lord Mayor, Alderman C. Petrie, is fast becoming a great institution for furthering the cause of both gardeners and farmers, the competition this year being really excellent. The greatest success in the show was achieved by Mr. B. Ashton, of Lathom Hall Gardens, who took many leading prizes, also the silver cup offered to the most successful exhibitor. Throughout the day, the show was well patronised by the nobility and gentry of the district, who came to admire, and were more than satisfied at the grand results attained. The fruit section was well represented, and included contributions from Hereford growers. For six culinary Mr. Geo. Faulkner came first with capital Warner's King, and Mr. W. Morgan second.

Mr. Morgan had splendid Blenheim Pippin for the best six dessert, Mr. J. Davies, Leominster, second with Ribston Pippin. Mr. T. Guy scored with Marie Louise Pear; and Mr. B. Ashton second with Louise Bonne of Jersey. For culinary Pears, Mr. J. Davis had the best in Uvedale's St. Germain. In the classes for special prizes Mr. W. Mackerell, of Formby scored strongly, taking firsts with Warner's King, Ribston Pippin, Pitmaston Duchess, and Beurré Hardy. For any other variety of fruit Mr. B. Ashton had very fine Muscat of Alexandria.

The show of Potatoes was a great one, some magnificent samples being seen, and nowhere could finer produce be found. For the best white early kidney, Mr. J. Johnson with Duke of York led; second, Mr. Tinsley, with May Queen. For Sutton's Early Regent, first Mr. J. R. Newton; Best of All won first and second for the early rounds, staged by Messrs. E. Alty and G. Ashley. For a second early kidney, Messrs. J. Johnson and T. Almond with Cole's Favourite and Crocus. For second early round, Messrs. T. Percival and B. Ashton with Royal Standard and Webb's Goldfinder. Early, or second early of any other shapes, Messrs. B. Ashton and E. Alty with Ideal and Standard. For Snowdrop or Lord of the Isles, Mr. Mackarell with the former; Colossals, Mr. E. Davies; Abundance, first Mr. Geo. Ashley; Satisfaction, first Mr. E. Davies. Up-to-Date, a grand entry; first, Mr. T. Reason; Maincrop, first, Mr. B. Ashton. For a late kidney, first, Mr. D. Oldfield, with Bank of England. For a late round, Messrs. B. Bowen and J. Johnson had Syon House and Fielder's Improved. Imperator and Scottish Triumph from the latter were the best late any other shape. Reading Russet, from Messrs. B. Ashton and E. Alty, was the premier early coloured round; and Peerless Rose, from Messrs. E. Davies and J. R. Newton, the best early or second coloured kidneys. Edgecote Purple, the best coloured late kidney, from Messrs. T. Reason and J. Johnson; the best late round was Purple Perfection from Messrs. E. H. Wood and E. Davies.

In the new varieties, Mr. Johnson won with Parker's Seedling, and Mr. Tinsley with May Queen as kidneys. In the new rounds, Mr. Johnson with Sunbeam, and Mr. Ashton with a grand looking seedling. For a new late kidney, first and special, Mr. B. Ashton with Webb's Empire. For a new late round, again Mr. Johnson won with a handsome variety named Victory; second, B. Ashton, with General Buller.

Messrs. Sutton's "specials" went to Mr. Johnson for Abundance and Ideal; and Mr. Ashton with Centenary. Sutton's Satisfaction from Mr. E. Davies was the best in its class. The prize for Reliance was won by Mr. Percival. Webb's "specials"

were won by Mr. Ashton with Webbs' Renown; by E. Davies with Webbs' Motor; and Mr. Haycox with Goldfinder. Messrs. Field's by Mr. Wilson with C. Fielder. Messrs. Kerr's, Dumfries, by Mr. Ashton with Enterprise. Messrs. Nivens by Mr. Johnson with General Buller, and Jno. Wilson with Pioneer. The best new Potato was Edward VII. from Mr. J. R. Newton.

Roots and vegetables were really grand, but space will not permit of full list being given. All the leading firms were thoroughly represented in grain, roots, &c.—R. P. R.

### Reading and District Gardeners' Mutual Improvement.

More than one hundred members assembled at the last meeting of the above association to hear Mr. George Gordon, V.M.H., deliver a lecture on "Beautiful Flowering Trees and Shrubs." Time did not suffice to give more than a running commentary on a magnificent series of photographs, shown by the limelight, illustrating some typical specimens of the double Peach, Almond, Magnolia, Cherry, Plum, Quince, Pear, Thorn, Laburnum, Genista, Berberis, Lilac, Deutzia, Viburnum, Exochorda, Spiræa, Stapelia, Hydrangea, Horse Chestnut, Catalpa, Wistaria, Azalea, Heath, Andromeda, Rhododendron, &c. The exhibits were exceedingly interesting, the honorary ones were a basket of Princess of Wales Violets (splendid blooms), retarded Potatoes (illustrating the method of obtaining young Potatoes all the year round), also a dish of fruit of Psidium Cattleianum (Guava) suitable for dessert or jelly by Mr. G. Stanton, Park Place Gardens, Henley-on-Thames. A collection of Sweet Peas by Mr. D. Agar, gardener to Milton Bode, Esq., Caversham. For Certificates, a batch of Michaelmas Daisies grown as annuals, seed sown in February, planted out in June, and potted in September (Certificate awarded) by Mr. F. Laver, The Gardens, Hillside, Reading, and a magnificent specimen of Orchid, *Odontoglossum grande* (Certificate awarded) by Mr. W. G. Pigg, The Gardens, Treveroli, Maidenhead. A hearty vote of thanks was awarded to Mr. Gordon, on the proposition of the president, for his interesting lecture. Four new members were elected. The subject for the meeting on October 27 will be "Sweet Peas," by Mr. House, Westbury-on-Trym.

### Metropolitan Public Gardens Association.

OPEN SPACES.—At the monthly meeting of the Metropolitan Public Gardens Association, held at 83, Lancaster Gate, W., the Hon. Dudley Fortescue, vice-chairman, presiding, it was decided (in response to a request) to support the Land Dedication Bill, introduced by Lord Balcarras, M.P., and others, to assist land owners to set aside ground for public enjoyment without necessarily having to part with their freehold interests. Communications were read from residents in Birmingham seeking advice as to steps to be taken to secure open spaces, and in giving the information sought, it was agreed to urge the desirability of forming organisations similar to the Association in provincial cities and towns, as centres of open space promotion and effort. It was announced that the Consistory Court had given judgment as anticipated in reference to the building of a parochial hall on Holy Trinity, Stepney, Churchyard Garden, to the effect that it was an enlargement of the church permissible under the Acts, and a hope was expressed that the case would be taken to a Superior Court. Seats were granted for the Dulwich Free Library Garden and Home Park, Lower Sydenham. A letter was read from the Stepney Borough Council agreeing to take over and maintain St. Mary's, Whitechapel, Churchyard, which the Association had undertaken to put in order. Satisfactory progress was reported as regards the laying-out of the Southfields Recreation Ground, Wandsworth; but it had not been possible to commence work at All Saints, Poplar, Churchyard, as the transfer of the ground to the local authority was still incomplete. It was agreed to make offers with regard to acquiring a site in Putney and three squares in Lambeth. It was stated that the erection of a drinking fountain by means of the generosity of a member in Charles Square Garden, Hoxton, had been completed. Donations from the Merchant Taylors' and Skinners' Companies of £10 10s. and £5 5s. respectively were gratefully acknowledged, and there was a need felt for further contributions, there being a considerable diminution in the receipts, owing probably to the adverse effect of the late war and allied causes.

### Royal Horticultural—Drill Hall, October 20.

The meeting on Tuesday last was again of great interest, and hardy flowers, Chrysanthemums, and vegetables were each exhibited abundantly. In the absence of Sir Trevor Lawrence, Bart., Harry J. Veitch, Esq., occupied the chair. The secretary, Rev. W. Wilks, M.A., announced the gift to the society's hall fund scheme of one hundred guineas, and read His Majesty's letter to the Fellows. He also intimated that Leopold de Rothschild, Esq., had promised a contribution to the same fund, of 500 guineas, and Mr. Wilks eloquently urged on any Fellow to do the most that they could to help on the work in hand. Lastly,

he stated that a record had been established in the number of new members elected during one year, for since January there have been 1,005 new Fellows' names added to the books, which surpasses all previous records in this line.

Mr. J. Godfrey, from Exmouth, presented an attractive selection of both early-flowering and exhibition varieties of Chrysanthemums. Amongst the former were the following: Gladiator, Kitty Crew, Harry Grover, Delightful, Mrs. E. V. Freeman, Pink Beauty, Mars, Godfrey's Pet, and October King, the colours being rich and good, and the former very pleasing. Among the exhibition blooms were those of the varieties Britannia, Grandeur, Masterpiece, Lord Alverstone, Kimberley, T. Humphries, Loveliness, Exmouth Rival, The Lion, Attraction, and Exmouth Crimson.

Messrs. Wells and Co., Earlswood Nurseries, Earlswood, Surrey, was also forward with a delightful group of the Autumn Queen, among which were noted R. Hooper Pearson (a fine exhibition flower of large size and good finish), Miss E. Fulton, Lord Alverstone, Mme. Von Andre, Mme. G. Henry, Mrs. T. W. Pockett, Chas. Longley, Miss Alice Byron, and a number of showy decorative varieties. The afore-named were all shown as single stemmed plants in pots.

Mr. H. J. Jones, Ryecroft Nursery, Lewisham, set up a very large group of pot Chrysanthemums, each bearing flowers of high exhibition merit. Early flowering sorts in front were as follows: Notaire Groz, Edie Wright, Market White, Goocher's Crimson, Horace Martin, White Quintus, Vivid, Lemon Queen, Bouquet de Feu, and Roi des Précoces.

Messrs. Barr and Sons had Colchicums and Crocuses, and the pretty *Nerine undulata*, &c.; Mr. J. Russell had berried Aucubas; and Messrs. Peed and Son staged foliage plants and Cattleyas. From Messrs. Veitch and Sons, Limited, came a brilliant contribution of the charming *Begonia incomparabilis* (bright rich scarlet crimson), and a selection of their hybrid winter-flowering Begonias. They also had hybrid Javanese Rhododendron trusses, and *Dædalacanthus parvus* in pots, the plants all being well grown.

H. J. Elwes, Esq. (gardener, Mr. Walters), Colesborne, Cheltenham, displayed a very pretty group of well flowered Nerines, and number of the varieties being new or little known. A group of Gloire Begonias, the white and pink varieties, all very large for the time of the year, was sent by Hugh Kerr, Esq. (gardener, Mr. Dunkley), Ardgowan, South Woodford. Mrs. Demison (gardener, Mr. A. G. Gentle), Little Gaddesden, Berkhamsted, was forward with a group of Michaelmas Daisies, in which were included a number of seedlings.

Mr. H. B. May, from Edmonton, had superb plants of *Adiantum Farleyense* and *Cordylines*, while Messrs. Bull and Sons gave variety and somewhat of novelty by a combination of huge Tree Ferns, Dicksonias, and *Cibotiums*. Messrs. B. S. Williams, Upper Holloway, N., staged perfect specimen *Cordylines* (*Dracenas*) in variety, all clean, even, and well coloured.

Perennial Asters from Messrs. Cutbush and Son were seen to great advantage, for the whole plants were set up. A number of good new named varieties were here, including Hon. Ed. Gibbs, Triumph, Golden Spray, cordifolius elegans, c. Diana, Theodora, Captivation, Coombefishacre, and others. They had also some beautiful Carnations. Messrs. Ware had hardy flowers.

From Messrs. J. Hill and Son, Barrowfield Nurseries, Lower Edmonton, there came a beautiful and varied collection of Ferns.

Messrs. Charlesworth and Co., Heaton, Bradford, had a very choice group of hybrid Orchids, including *Cattleya Bowringiana*-superba, *Lælia-Cattleya Goltiana*, *Cattleya* Mrs. J. W. Whiteley, magnifica, *Lælia-Cattleya* La France, *Cattleya* Mrs. Herbert Greaves, &c.

Walter C. Walker, Esq. (gardener, Mr. Geo. Cragg), Percy Lodge, Winchmore Hill, N., had a group of *Odontoglossums*, while from J. Bradshaw, Esq. (gardener, Mr. G. E. Whitelegg), The Grange, Southgate, there was a collection of *Cattleyas* (well-flowered plants), *Odontoglossums*, and *Oncidiums*. Baron Schröder, Sander and Sons, Mr. Gurney Fowler, and also Hugh Low and Co. staged Orchids.

Major Bythway (gardener, Mr. W. Wilkins), Walborough, Llanelly, S. Wales, contributed a brightly coloured collection of Apples, comprising over seventy dishes of the best sorts. From the appearance of the fruits it was evident that very considerable care had been expended on their culture. Mrs. Arnold, The Lodge, Dedham, also had a few dishes of Apples.

R. W. Hudson, Esq. (gardener, Mr. J. Gibson), greatly added to the interest of the meeting by the highly creditable display of vegetables he had on this occasion. It seemed as though every sort of vegetable that gardens grow was here, all nicely staged, and the products fresh and good. The Eclipse Cauliflower were very fine samples; Gladstone Pea and Sutton's Giant French Asparagus were meritorious, Potatoes were splendid, as, indeed, was everything staged; but on viewing the wonderful variety of them, we found it beyond our space and time to try to detail them. The collection were all grown from Messrs. Sutton and Sons' seeds. A Gold Medal was unanimously awarded.

Messrs. Cannell and Sons, Swanley, staged vegetables, including Cannells' Defiance Cabbage, Cranston's Excelsior

Onion, 'Cannells' Prizetaker Onion, 'Cannells' Autumn Giant Cauliflower, and many varieties of Potatoes and other products of the kitchen garden.

#### Medals.

**FLORAL COMMITTEE.**—Silver-gilt Flora for group of Chrysanthemums to Messrs. Wells and Co., Red Hill, and Mr. H. J. Jones, Lewisham. Silver Flora for Michaelmas Daisies to Messrs. Cutbush and Sons, Highgate; for Adiantum and Dracænas to Mr. H. B. May, Upper Edmonton; for Carnations and Chrysanthemums to Mr. W. Godfrey, Exmouth; for Polypodium to Messrs. J. Hill and Son, Lower Edmonton; for winter flowering Begonias to Messrs. J. Veitch and Sons (Limited), Chelsea. Silver Banksian for Tree Ferns to Messrs. Bull and Sons, Chelsea; for Nerines to Mr. H. J. Elwes, Cheltenham. Bronze Banksian for Chrysanthemums to Messrs. Cannell and Sons, Swanley; for fruiting Aucubas to Mr. J. Russell, Richmond; for hardy flowers to Messrs. T. S. Ware (Limited), Feltham, and Messrs. Barr and Sons, Covent Garden; for plants to Messrs. B. S. Williams and Son, Upper Holloway.

**ORCHID COMMITTEE.**—Silver Flora to Messrs. Charlesworth and Co., Bradford, for group of Orchids; to J. Bradshaw, Esq., Southgate, for group of Orchids; to Jas. Veitch and Sons (Limited), Chelsea, for group of hybrid Orchids. Silver Banksian to Walter Walker, Winchmore Hill, for group of Orchids; to Messrs. Sander and Sons, St. Albans, for group of Orchids; to J. Gurney Fowler, South Woodford, group of Orchids; Messrs. Hugh Low and Co., Enfield, for group of Orchids. Cultural Commendation to F. Wellesley, Esq., Westfield, Woking, for Catt. Maroni; to Sir Trevor Lawrence, Bart., Burford, Dorking, for Angraecum; to H. J. Elwes, Cheltenham, for Habenarias.

**FRUIT COMMITTEE.**—Gold to W. H. Hudson, Esq., Danesfield, Marlow, for a collection of vegetables. Silver Knightian to Messrs. Cannell and Sons, Eynsford, Kent, for collection of vegetables. Bronze Banksian to Mrs. Arnold, The Lodge, Dedham, for collection of Apples. Silver-gilt Knightian to Mr. Bythway, Llanelly, S. Wales, for collection of Apples.

#### Certificates and Awards of Merit.

*Anemone japonica* var. *Queen Charlotte* (Barr and Sons).—Flowers large, strong, coloured a deep rosy Apple-blossom shade purplish on reverse side. (Award of Merit.)

*Nerine flexuosa alba* (Barr and Sons).—A Botanical Certificate was awarded.

*Apple, Edward's Coronation* (Hon. H. B. Portman).—Slightly over medium size, roundish; skin greenish yellow, streaked and mottled red on the side next the sun; eye set in a round depression, somewhat deeply, and wide; stalk straight, stout,  $\frac{1}{2}$  to  $\frac{3}{4}$  in long, in deep round cavity. Flavour very good. (Award of Merit.) From Buxted Park (gardener, Mr. H. C. Princep), Uckfield.

*Lælio-Cattleya* × *Bletchleyensis*, *Fowler's* var. (J. Gurney Fowler, Esq.).—Parentage, *Lælia tenebrosa* × *Cattleya Warscewiczii*. The flower is very large and graceful, the petals and sepals curve forward, the petals being very much waved at the edges. They are 2 in broad in centre, and  $4\frac{1}{2}$  in long, coloured purple. The lip is long and protruding, velvety-purple, a very great feature. (First-class Certificate.) From The Glebelands, E. Woodford.

*Lælio-Cattleya* × *Mrs. Chamberlain* (Right Hon. Jos. Chamberlain).—The parentage is *C. chocoensis* × *Brassavola Digbyana*; the latter tells in the lip, which is nicely fringed and coloured pale mauve. The graceful petals are nearly white. (Award of Merit.) From The Gardens, Highbury, Moor Green, Birmingham. Grower, Mr. Mackay.

*Odontoglossum delicata crispum* *Harryanum* (Baron Sir Henry Schröder).—The flowers are large, with pale coloured segments, white at the base and heavily spotted with chocolate colour; the lip is large and white tipped, also speckled and marked with brown, and has a yellow blotch on the claw. The plant bore a six-flowered raceme. (First-class Certificate.)

*Nerine Miss* × *Carrington* (H. J. Elwes, Esq.).—Umbel large, and likewise the individual flowers, which are coloured rosy-purple, the segments twisted and reflexed from about the middle. (Award of Merit.)

*Chrysanthemum Miss E. Fulton* (Wells and Co.).—Very much like Princess Alice de Monaco; a nice rounded flower. (Award of Merit.)

*Chrysanthemum Hon. Mrs. Ackland* (Right Hon. W. F. D. Smith).—A grand Jap., after the R. Hooper Pearson type, but the yellow is of a very different shade, rich, bright, intense. A grand deep flower. (Award of Merit.) From Greenlands, Henley-on-Thames.

*Chrysanthemum Mme. Paola Radaelli* (Mr. N. Davis).—Flowers of enormous size; an incurving Jap. of a lilac tint and paler centre. (Award of Merit.) From Framfield, Sussex.

*Cimicifuga japonica* s *mplex* (Leopold de Rothschild, Esq.).—A late flowering form of a good border plant. (Award of Merit.) From Gunnersbury House, Acton.

## THE BEE-KEEPER.

### Uniting.

One of the peculiarities of bee life is that if strange bees enter a hive with intent to rob they are immediately detected and expelled or killed, but if loaded with honey they are joyfully accepted.

This knowledge properly applied enables the bee-master to mix bees apparently indiscriminately. The ability to unite colonies is at times as useful and necessary as it appears difficult to the uninitiated. The operation is generally performed in October, with the object of preserving or strengthening weak lots, which, if left to winter singly, would succumb to the intense cold. The chances of successfully wintering these small stocks are slight, and the attention they require in spring is so great that it is more profitable in many ways to winter them in one lot.

Bees may be united at any time of the year, but for winter purposes October is the best month. The cool weather causes the bees to adhere to the combs, and they do not fly much at this period.

Many amateurs make fatal mistakes in performing the operation without realising that a very little more knowledge, or trouble, would have resulted in an almost perfect union. The whole process where bar frames are concerned need not take more than a few minutes. To ensure success it is absolutely necessary that the bees should be brought to precisely the same condition, and only one queen left. A puff or two of smoke administered at the entrance of each lot will frighten them, and cause them to fill themselves with honey, after which, open the hives, move the combs so as to admit daylight, and lift out with the adhering bees, placing them alternately amongst those of the receiving hive, or if preferred they may be lifted "en bloc."

Where there are more bars of bees than one hive will accommodate, select those with brood on them, cover up, and the union is complete. A wide board placed from the

An Improved Plant Barrow.

entrance to the ground makes the bees mark the location, and also prevents them returning to the wrong hive, causing fighting. The greatest cause of fighting, however, is the manner in which the union is made. One part of the process is to subdue the bees properly, and where there are no unsealed stores this is impossible. It is useless attempting a union until they are properly filled with honey. Hungry bees are never easily united. If there are no unsealed stores they must be fed or sprinkled with thin syrup. Success lies in having colonies about the same strength, in the same condition, and perfectly free from irritation.

In cases where stocks are a distance apart bring them close together by moving a foot or so at intervals of a day or so. Whilst on this ground, it may be well to correct the erroneous impression that prevails amongst a section of British bee-keepers, that driven bees can be united to those on bar frames by running them in at the entrance. This is only wild speculation. The advocates of the plan know as much about the operation as (to use an Americanism) would fill a Filbert. They appear to entirely ignore the fact that bees which are not on frames never successfully unite with those on frames.

The only method by which this may be accomplished is to remove the oldest queen; shake the bees of the established stock off the frames on the alighting board, and then as they run in throw the condemned bees amongst them, afterwards replacing the combs. Even this method, with the extra labour of spraying with peppermint, &c., is not always certain, and if fighting ensues the smoker should be freely used, and the hive sides thumped heavily. This will generally restore order.

Where it is impossible to bring stocks close together, deprive the stock of its queen and brood. Two days afterwards it can be readily united to any other colony in the apiary which is in possession of a fertile queen. Another plan which does not necessitate the removal of the brood is to remove the queen, and eleven days afterwards go carefully through and destroy all queen cells. Two days afterwards unite them some evening by the alternation of bars method. The explanation of this is that if bees are rendered queenless, and are so placed that they have no means of raising another, they will, when joined to a colony in possession of a fertile queen, remain in any position.

Bees which have been in transit, confined, or overheated, should not be placed together until they have cooled down. The cooling process is carried out by placing them near the hive to which it is intended to unite them, and removing the cover of the receptacle so as to permit flight. Leave them in this condition for twenty-four hours. They can then be united with perfect safety by the method before mentioned.—E. E., Sandbach.

## Young Gardener's Domain.

Willie's Wall.

Willie was a chorister in the old Abbey church of Borderchester, where he long rendered efficient service as "principal treble." He was a boy of refined tastes, delighting not only in vocal music, but in the execution of Bach's fugues and the like on the pianoforte, in water-colour drawing, and in the cultivation of flowers. But his only garden was a very narrow strip of soil at the top of a wall in his father's backyard. This little border could only be reached by a ladder, and could only be seen either from an upper window or from behind a wooden fence. Here Willie cultivated Snowdrops, Crocuses, Daffodils, and Tulips, followed in due course by Polyanthus, Pansies, Sweet Williams, and other flowers. He had also a thriving bush of Rosemary, and some fancy Ivies and other creepers to run down the wall.

The neighbours would often look over the fence to admire the flowers, and as Willie emerged from boyhood and began to pay more attention to personal appearance, he might often be seen with an elegant "buttonhole" culled from his own garden.

Of course, like other gardeners, Willie had his troubles. The city cats found that his garden afforded a delightful promenade, and they disturbed his slumbers not only by their nightly concerts, but by fears for his flowers. They would wander on the wall in the daytime as well, and Willie's tiny sister Mary has been known to risk her little life and limbs by trying to mount the ladder, not to meddle with her brother's flowers, but to drive away the cats. Thus we see what may be done in the way of gardening under difficulties, and readers in towns and cities may perhaps be glad of the suggestion afforded by "Willie's Wall."

—J. F.

## TRADE NOTE.

An Improved Plant Barrow.

The adjoining figure illustrates the improved plant-barrow referred to on page 339 by Mr. R. E. Sanders in his remarks under the heading, "Wanted—Inventors." It explains itself. The patentee and maker is Mr. John Sanders, builder, 24, Downside Terrace, Hampstead, London, N.W.

## Fruit Forcing.

**PEACHES AND NECTARINES: EARLIEST FORCED HOUSE.**—The trees are now at rest and promise well, the buds of the standard varieties, such as Royal George and Stirling Castle, not being too large. This is a good sign, as Peaches and Nectarines subjected to early forcing year after year are liable to have the buds swelled to a large size, and these not unfrequently fall when they should be starting into blossom. Some kinds are more prone to this than others. Of the very early kinds, Alexander and Waterloo are the worst, often casting most of the buds, and it certainly is due to over-development, as the buds on the sub-laterals (as occurs from stopping when the trees are grown on the standard system) are retained, and the blossoms develop perfectly and the fruit sets freely, while on the first made part of the wood of the shoots the buds are large and drop in showers.

Hale's Early, the very best of the early Peaches, taking quality into consideration, casts many buds, being little better than Early York, which drops the buds alarmingly. Noblesse, however, stands at the head in liability, to cast its buds, then comes Grosse Mignonne, and both these have a tendency to form double or triple fruit buds without a wood bud at the same joint, also to form buds with two or three pistils in embryo, in due course developing into twin or triplet fruit. This is what is meant by over-maturity of the buds, and is common to all large-flowered varieties of Peaches and Nectarines, which probably arises from a prolonged season of growth, with a decided tendency to over-production.

The small-flowered varieties, such as Early Louise, Stirling Castle, Royal George, and Dymond Peaches, and are the best of early forced, being high in colour and of unquestionable quality. Of Nectarines, Cardinal, Early Rivers and Stanwick Elruge are excellent for early forcing. Bud-casting seems influenced to a great extent by treatment, and in the case of early forced trees it is necessary to keep them as cool as possible after the fruit is gathered consistent with their safety, even shading where the panes of glass are large and the weather bright and hot for prolonged periods, and remove the roof lights when the wood becomes sufficiently matured. Where this has been done the borders have got thoroughly moistened to the drainage, and when that is the case, and the buds are not over-matured, there is relatively little danger of their falling.

The trees should be pruned, the house thoroughly cleansed, limewashing the walls with a handful of flowers of sulphur added to a pailful of limewash, and the trees washed with a tepid solution of carbolic soap, 1½ oz to a gallon of water, using a brush and taking care not to dislocate the buds. This may be followed by a more powerful insecticide, the petroleum emulsion, and, indeed, all oils or fats, properly saponised, emulsified, or made soluble and innocuous to vegetation, having fungicidal as well as insecticidal value. Tie the trees to the trellis, forwarding everything so that a start can be made when the proper time arrives. The roof lights should remain off until the time of closing the house, or if the lights are fixed, which is a great mistake, as it causes the trees to be subjected to alternating fluctuations and depressions, both of heat and moisture, the inside borders must not lack moisture, but be made and kept in a damp state down to the drainage, and air be given to the fullest possible extent. No amount of frost will injure properly matured wood, and the buds are never injured by frost until they commence growing.

**SECOND EARLY HOUSE.**—For second early forcing there are no better than Hale's Early, A Bec, Stirling Castle, Royal George, and Dymond Peaches; Rivers' Early, Lord Napier, Stanwick Elruge, Humboldt, and Dryden Nectarines. The trees have for the most part cast their leaves, the roof lights having been off some time, for if kept over the trees longer than is usual, as sometimes is necessary when the wood is strong to mature it properly, they must now be removed. The ventilating lights, both top and bottom, may remain, so that the fixing and refixing of them is obviated, while the trees have complete exposure to atmospheric influences. The exposure has an invigorating effect, it secures perfect rest, and the rains do much to free the trees of insects, besides thoroughly moistening the borders. When the foliage is all down the necessary pruning, dressing with an insecticide, and the cleansing of the house should be proceeded with, removing the surface soil down to the roots and supplying fresh material, but not covering the roots deeper than 2 in or 3 in. In the case of fixed roofs, water may be

necessary. Under no conditions must the trees be allowed to become dry at the roots.

**MIDSEASON HOUSES.**—The trees in these are just in the right condition for lifting. It should be done with dispatch when it is decided on, having all the materials in readiness. It is not, however, safe to operate until part of the leaves have fallen, yet not wise to wait till the green leaves on the laterals mature, as these will not drop for some time, and they may be useful in prompting root action in lifted trees. Provide efficient drainage, shortening back any strong roots, and bring any that are deep nearer the surface, laying all in the top foot of soil, and employing the compost compactly. Good loam, rather strong, with a sixth of old mortar rubbish admixed, will grow Peaches and Nectarines perfectly. If the soil be light, add a fourth of clayey marl, dried and pounded, and if very strong a similar quantity of road scrapings, avoiding manure excepting the soil be poor, then add a fifth of decayed cowdung to light, and a similar quantity of horse droppings to heavy loam. Give a good watering after lifting and replanting, and the trees will soon get established in the fresh compost. Trees judiciously treated at the roots seldom fail to set and stone the fruit satisfactorily. Borders containing soil in a soapy mass, where it is not possible to remove it, may have a dressing of air-slaked lime—an inch thick is not too much—mixing it, after laying a few days with the surface soil as deeply as the roots will allow without disturbance. Nothing, however, is so effectual as lifting and renovating the border.

**LATEST HOUSES.**—Except the latest varieties, of which Golden Eagle is one of the best, the fruit is all gathered. Trees from which it has been gathered should have the bearing wood of the current year cut out, leaving only so much wood of the current year's production as is required for filling vacant space and affording fruit next year. The foliage should be thoroughly cleansed of dust or insect pests by a few good washings from the syringe or garden engine. After that the trees will not require syringing, dryness with thorough exposure of the wood to light and air being essential to the perfecting of the wood and buds. Where this is not effected the house may be kept rather close by day, so as to secure a good heat, there being, of course, enough to secure a free circulation of air, and the house should be fully ventilated at night. Any trees that have to grow wood should have a trench taken out as deep as the roots and about one-third the distance from the stem, leaving it open a fortnight, then filling it firmly.

### Kitchen Garden.

**CARROTS.**—Root crops, including Carrots of the various types—Short Horn, Intermediate, and "Long" varieties—should all be lifted before the weather becomes decidedly wet. Lifting the roots and preparing them for storing is much pleasanter work when the ground is dry and clean to tread upon. The roots also will dry quickly, and are in much better condition for the necessary storing than when wet soil adheres to them. Loosen the roots carefully with a fork, when they will readily withdraw. Cut off the foliage within an inch of the crown. Should the weather conditions be favourable, the roots will, after lying upon the surface of the soil for a day, be sufficiently dry to store away. The method of storing for all the best-shaped roots of good quality is to place them in a cool outhouse on a dry bottom, arranging them between layers of dry sand or ashes. The less shapely and important roots should be placed in a heap in a dry corner, covering with straw or any dry material.

**BEETROOTS.**—These roots are better out of the ground now that growth is practically ceasing and the soil is becoming very moist. Accomplish the lifting with the utmost care, so as not to break the thicker portion of the tap root, which causes the roots to bleed and lose colour. This can readily be avoided by gradually easing the roots in lifting. For the same reason, the leaves must not be removed too closely to the crown, and instead of cutting off the leaves, twist them off well above the crown. The roots will keep well in soil or sand in a position safe from severe frost.

**CELERY.**—Where there is a brisk demand for well-blanching roots of Celery throughout the winter, the supply cultivated must be ample, including a good breadth of late plants. The final earthing of these may be deferred as long as possible, though the blanching may be commenced by several preliminary earthings, applying the final when growth is finishing and the approach of frosts inevitable. Drawing the leaves together, and lightly securing them with raffia grass, is also a means of slightly blanching; but the chief purpose of this is to prevent loose soil reaching the hearts of the plants when earthing. The earthing process should be carried out in fine weather, when the Celery is dry and the soil not sticky. Press the soil firmly round the plants, and, except when finally earthing, do not carry the soil above the hearts. Bank the sides fairly steep, so as to carry away the rain.

**MUSHROOMS.**—A succession of Mushroom beds made in any warm outhouses or sheds will provide some profitable crops

over a considerable period. Fresh horse droppings should be collected in a dry shed, preventing them heating until a good heap of material has been brought together. Then form into a cone-shaped heap, and, after a few days' fermenting, turn the manure, placing the outside inside, and vice versa. This must be continued until the whole of the rank heat has been expelled, when the beds may be made up. Three or four feet is a good width; the length must be governed by the space and material, but the depth ought not to be less than a foot when the materials have been trodden together, or otherwise packed firmly. The spawning must be regulated by the heat of the bed. If the temperature should rise above 90deg., which can be ascertained by a plunge thermometer, defer the spawning until the temperature declines to 85deg. Good, active spawn should be used, breaking bricks into pieces about the size of eggs. Make holes in the manure 9in apart, and bury them just below the surface, working the manure firmly round and over each piece.

Soiling the bed is the next process. It may be done at once or deferred for a few days. Employ some good fresh soil, placing it about an inch and a half thick. Beat it down firmly with the back of a spade, and leave the surface smooth.—EAST KENT.

\* \* All correspondence relating to editorial matters should be directed to "THE EDITOR," 12, Mitre Court Chambers, Fleet Street, London, E.C. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense.

**BOOK WANTED** (J. Cleland).—A book giving the English and Latin names of plants is published by Collingridge and Co., entitled an "Encyclopædia of Gardening," which was published in 1895, and costs 3s. or 4s. You should write to the publishers, at 148, Aldersgate Street, London, E.C.

**STEPPING DUTCH BULBS IN PARAFFIN OIL BEFORE PLANTING** (T. J. R.).—We have not known a successful trial of the procedure you name, and are also doubtful as to its not injuring the bulbs, for though we have used paraffin for moistening seeds before sowing to save them from the attack of mice and other predatory pests, finding the treatment very effectual in the case of Beans and Peas, and red lead for coating small seeds, we have no experience of treatment of bulbs with paraffin oil, and think it likely to get between the scales of the bulbs, if not into the crown, there injuring the living tissues, and possibly outside damaging the base from whence the roots issue. Red lead might act to some extent as a deterrent of the rodents taking the bulbs, but even of this we have no experience, for we find it better to trap the animals, commencing baiting and trapping in advance of planting. It is likely that soaking the bulbs for about half an hour in a solution of formalin, one part formalin in 400 parts soft water, would probably prevent the mice, &c., from taking the bulbs. It is a poison, and certainly useful in destroying the germs of fungoid pests; also animal ones, such as root-mites, eelworms, &c.

**EXHIBITING CHRYSANTHEMUMS** (De War).—Next week we hope to furnish a rough diagram affording an illustration of the method generally adopted for conveying specimen Japanese Chrysanthemums on long stems to the place of exhibition. It is in the form of a strong deal box, which can be painted green or slate-coloured on the outside. On the inside two wooden rods are placed from end to end, one at a higher elevation than the other, the upper one high enough to come just below the bloom fixed to it. The long stem should rest in a vessel of water, and be tied to the cross-rods in two places; a little wadding or soft paper being wrapped round the stem where the tie is placed, so as not to cut into it in any way. This is the method generally employed by competitors who exhibit in the large vase class at the Royal Aquarium, and the flowers are conveyed in this way long distances without taking injury, and come out of the boxes quite fresh. As we did not see the Chrysanthemum shows at York or Edinburgh in the autumn of last year, we are not in a position to draw comparisons. We cannot inform you regarding the relative positions of flowers at Ebor and "Edina" (Edinburgh?), but if the latter is referred to, then certainly the quality is of the very highest.

**QUERY.**—A correspondent enquires about an illustration which appeared in a London paper some short time ago, of a budding instrument called the "Galbreath Budder." He asks: "Could you send me an illustration of same, give me name of inventor, address where sold, and cost?" Any information relative thereto will oblige our correspondent.

**EPIPHYLLUM CULTURE** (Idem).—They should have enough water to keep the soil moist, but not sodden, and after flowering they should have no more than sufficient to keep the stems plump until they are started into growth in the spring, then water freely and keep moist. They will flower well in a temperature of 45deg, but may be forwarded in a stove. The flowers endure longer in a greenhouse than in a stove. A greenhouse is most suitable for them, with extra heat when making new growth.

**VINES AGAINST END OF HOUSE** (F.I.).—Plant the Vines a yard apart 18in from each end, and the rods we should take upright, and cut them back to 3ft, depressing the canes in spring so as to ensure their eyes breaking regularly. When these have broken disbud so as to leave the shoots at 18in apart on both sides of the rod, taking the first at about 1ft from the soil. You will require to retain one shoot as a leader in addition to the side shoots. Vines trained upright always break much more strongly at top than bottom, hence it is good practice to train the rods in the serpentine form, and originate the shoots from the horizontal parts at 18in apart, that distance being left between one curve and the other next above it.

**HYACINTHS IN GLASSES** (A Lady Amateur).—Place the bulbs in the glasses after filling the latter with soft water so that the base of the bulb just or barely touches it, always keeping the water to that level, and removing it whenever it becomes impure, as may be known by the ends of the roots looking woolly; then replace with fresh which has been kept overnight in the room with the plants to acquire the same temperature. To keep the water longer sweet, a piece of charcoal about the size of a small walnut may be placed in each glass. Set the glasses in a cool and dark cupboard until the roots have formed, but remove them to the light before the crown has grown an inch, and then give air daily if mild weather, but do not stand the glasses on stone, brick, or iron, but on wood. The plants may be sprinkled overhead every day with rain water until they come into flower, which greatly invigorates them. Avoid frost, wind, and a close room, and keep them off the mantelshelf. A window is the best place. October is the best time to place the bulbs in the glasses.

**FREEING LAND FROM SLUGS** (V.T.).—The best means is to give the land a dressing of gas lime, fresh from gasworks, applying  $\frac{1}{2}$ cwt per rod, spreading evenly, and leaving a month or six weeks before digging in. The smell, however, is offensive, and it may not be used over the roots of fruit or other trees, but only on bare ground, and that not cropped until spring. A dressing of quicklime is effective, applying 1cwt per rod, placing in little heaps, slaking with the smallest amount of water necessary to cause it to fall into an apparently dry powder, and spreading whilst hot, leaving on the surface a day or two before digging in, and choosing dry weather. This is preferably done in the autumn. In spring, before sowing seeds or setting plants, the ground may be dressed with nitrate of soda, finely crushed, spreading evenly, at the rate of 1 $\frac{1}{2}$ lb per rod. It should not come into contact with seed or plants; therefore, apply before taking out the drills. Taking the crown bud is removing all the buds on a branch but the central one, and is usually that of buds of a shoot on the second break. It is, however, too late for crown buds, yours being what is known as terminal bud, and this is also the terminal bud of a shoot, and the removal of all the buds of a shoot but the terminative is all you can now well practise. The operation is a very simple one, but difficult to explain without illustration. This is given in Mr. Molyneux's "Chrysanthemums and their Culture," price 1s., which you should procure.

**NAMES OF FRUITS.**—Correspondents whose queries are unanswered in the present issue are respectfully requested to consult the following number. (X. Y. Z.).—1, Cox's Pomona; 2, ditto; 3, Beauty of Kent; 4, Cellini; 5, a local variety; 6, Yorkshire Beauty. (A. R. T.).—A, Lady Henniker; B, Tower of Glamis; C, Reinette de Canada; D, Warner's King; E, Cox's Pomona; F, Rymer; G, Northern Greening; H, Hollandbury. (J. Merrick).—1, Beauty of Kent; 2, Golden Noble; 3, Broom Park; 4, Gansel's Bergamot; 5, Eyewood. (P.).—1, Hoary Morning; 2, Peasgood's Nonesuch; 3, Beauty of Kent.

**NAMES OF PLANTS.**—Correspondents whose queries are unanswered in the present issue are respectfully requested to consult the following number. (J. Bertram).—1, Aster Novæ-Angliæ lævigatus; 2, Rudbeckia speciosa; 3, Linaria montana; 4, Helianthus multiflorus; 5, Azara microphylla. (L. M.).—1, Begonia argenteo-guttata; 2, Begonia Bruanti; 3, B. Vershaelti; 4, B. rex var.; 5, B. acuminata. (Zoe).—1, Begonia Dregci. It is of very great assistance to us to have representative samples to name from, by which we mean a portion of stem as well as leaves (and flowers, in flowering plants). (N. T.).—1, Salvia azureus; 2, Adiantum Williamsi; 3, Phrynum variegatum.

## The Hand to the Plough.

The plough is typical of agriculture, and very properly so. Without the plough or its equivalent the land would remain unprofitable and foul. The plough comes to us as one of the oldest known cultivators, and it will remain as long as seed time and harvest return. There are many hindrances to the work of the plough, and they are widely different as the points of the compass. Last autumn we were bemoaning that with harvest finished early, and fine days, we were not able to take advantage of the extra bit of time in hand that we had, simply because the ground was iron bound; not in the hands of frost, but in those of drought, an equally perplexing situation. How we longed and hoped for a change in the weather.

There is in this neighbourhood a certain town which holds its annual, and very large, fair on October 11, and it is proverbial that this fair rarely takes place except with a downfall of rain. Well, we waited and hoped for the 11th, for at last we should stand a chance of moistening showers; but lo! the 11th dawned and closed fine, neither did the succeeding days bring the desired change. When we did get the rain, ploughing went on merrily. This year we are late all round; hay harvest barely finished before the Corn was ready. The Corn harvest is dragging out its weary length, and, despite harvest festivals, is far from finished yet. Soaking sheaves cannot be led, and no ploughing can be done (or very little because of the condition of the ground). There are certain adventurous spirits who will be on, weather or no; but it is certain to the thinking man that more harm is being done than good; that is, on lands of any depth or solidity.

Of course, there are light lands that won't retain water at all, but we are now speaking of the generality of soils. There is just now so much to be done and so little time in which to do it. We have spoken of those whose harvest is not yet finished (a neighbour has fifty acres of white Oats out to-day). He certainly has no men or horses to spare. It was an old practice to have the seeds ploughed before harvest, and this went far to ensure a good seed bed, not too fresh or light, but this also was in the good times when the Wheat crop was the great stand-by. Now we grudge giving up the seeds so long as there is a bite of any sort, and certainly many of us are busy with our seed pastures when we should be turning our attention to those Wheat stubbles which we intend for Barley, or which need preparation for next year's roots. Then there is the land that was occupied by the Mangold plot, and in many districts the great area that was under Potatoes. We are somewhat afraid there is a growing tendency to slip ploughing Potato land; it is a mistake; but we expect often time presses, and, at any rate, there is not much rubbish left after a good crop of Potatoes.

Land, too, intended for next year's Potatoes must be worked so soon as possible. One neighbour, who has a good many irons in the fire, has much of his ploughing done by steam power. It certainly sets his forces free for other work, but he is a man with a long pocket. We spoke of the harm done by ploughing when the land was very wet; this refers especially to strong, tenacious land. Land of this description is fully stored with plant nutrition. Water and air liberate this, and make it active; but unless the land is fairly dug at the time of ploughing, you defeat your own object. Strong land ploughed wet turns up like a piece of liver, and is perfectly impervious to water or air. Nothing will do it good till frost comes, and often by that time the proper seed season is far past. The earlier seeds are ploughed up the greater chance there is of the destruction of insects and grubs and wireworm by the birds; they are then nearer the surface of the soil; cold weather sends them quickly down.

Some farmers in their anxiety to gather up and use every morsel of green stuff, allow their ewes to feed on the green tops of the field Mangolds. This is poor keep for ewes, and they do not return to the land the value that would accrue to it were the green leaves ploughed in. The leaves, in other words, are a better manure in a raw state than when they have been passed through a sheep. It is always poor economy to underfeed the breeding ewes.

There is nothing that looks better than good even ploughing; but this, like many other agricultural arts, is much neglected. The young men won't learn, and the old ones are dying off. We hear much, too, nowadays of the digging plough; it perhaps does better more satisfactory work, but with less neatness to the eye. To make a good job, good weather is needed, also a sensible man and a pair of good horses. We wonder how many of our readers saw that cartoon in "Punch" depicting Lord Salisbury as a ploughman leaving the completed field after having finished his last furrow. How people praised it, it quite took the popular fancy, but—the artist forgot one thing. There was the field, the plough lay idle, and the weary ploughman was homeward bent; but where were the horses? He would have looked more true to life had he been sat sideways on the near side horse; but we can't expect artists to know every little detail of farm life!

On the subject of the horses, it is well to remember that October often finds them a good deal out of condition. They have had heavy harvest work, and possibly with it high living, and now they have still heavier work under unpleasant atmospheric conditions. We know it is the custom on some farms where the arable land is far off to make what is called "one yoke," i.e., not coming home at dinner time, or, at least, not till a three o'clock dinner. The horses then are often over-tired and overheated, and don't clear out their mangers as they should. We do not think it altogether a wise policy.

We saw some ploughing (?) only to-day, the aim and object of which we could not divine; or, rather, we guessed at the reason. We saw some perfect clean stubbles being ploughed with a three-furrow plough, drawn by three horses; depth of the furrow, 3in. We suppose this was done so that the owner could say the land had been ploughed; but the benefit could be but a mere nothing. We think had an American cultivator been used instead (which would have taken a breadth of 5ft and penetrated 5in) the result would

have been much better. Of course, should that land be reploughed in the spring, the position will be altered; but we doubt much if that field will see a plough for a long time to come. To destroy Thistles and rubbish the ploughing must be deep, and the sods must be buried.

Where fields are being ploughed for Potatoes, it is a question of very deep work, and no furrow is good enough unless 8in to 10in deep; that is, if the soil will allow of it. If it does not, well, then, all we can say is that that land is not for Potatoes. It is well to consider what grand work the frost, rain, wind, and sun will make of a field thus ploughed. There is another point about ploughing which it is well not to lose sight of. Nowadays every lad is as good as his master, and can make every bit as perfect work; and so these young ploughmen look down with contempt on ploughs with wheels; they can plough without them, and much prefer it. Of course, it is better style, and would gain them points in a ploughing match, but we very much doubt if the innovation is a good one for the land or the master's interest.

"Why?" you will ask. Ploughing is hard work, that is, if properly done, and slow work, and there is much of it, and human nature would not be human nature if the lads did not try in some way to ease themselves; therefore, if left to themselves with a wheelless plough they may make excellent work while the master or the foreman is on the look out, but directly their backs are turned up comes the share, and the work gets to be very superficial and light. They ease themselves and their horses at the expense of good tillage, and get gaily over the ground. There is more robbery done in this way than the casual observer would detect.

If a lad is set to work with a wheel plough, and care is taken that he does not alter the wheels, he is bound to make the furrow of uniform depth. There will always be a fight over the matter, wheels or no wheels; but the master should be very firm, except in those cases where the ploughman is an old and trusted servant, one who really takes an honest pride in his work. It is not Wheat sowing just yet, or there might be some very unsatisfactory seed beds. Wheat must have a firm, solid foundation to do well, whereas Barley requires something light and friable. It is well so soon as ploughing is done to sadden the land with the presser.

### Work on the Home Farm.

It has been a dreadful week: rain! rain!! rain!!! The horses have been usefully employed in ploughing, but it has been anything but pleasant for them and the ploughmen. We never saw ploughing better done; and if it had been September and not October, the prospect for Wheat sowing would have been good. As it is, we must sow soon, though the ploughing be only just finished, and unless we can use the roll freely, which seems very unlikely at present, the seed bed cannot be firm enough to prove satisfactory. We have noticed a field or two harrowed down for drilling, but not seen a drill working yet. Truly, one late season begets another.

Potato lifting is at a standstill. One day's work in a week makes poor progress, and our Irish hands are becoming impatient with the delay. We saw to-day a party of them amusing themselves by ratting in a hedgerow. Possibly they were tired of vegetating in the granary; perhaps they had hopes of finding a rabbit and having a pie.

Notwithstanding the wet weather, there are few diseased Potatoes as yet. The crops are not as heavy as last year, but quite up to the average, and with less disease, that is so far as our observation goes, and it has extended over some 500 acres on ten farms during the past week. Professor Maerker is very good, but new Scotch Up-to-Date seed from Dunbar beats all. If the new kind, "King Edward VII.," proves superior, it will, indeed, be a "Champion."

Our good report of live stock has at last to be modified. There is a great deal of trouble amongst lambs. They have been suffering from a cough for two or three weeks, but that is very usual at this season. Events prove that the cough was caused by worm in the throat, and those farmers who did not drink their lambs when they were well as a preventive measure, are suffering losses, and drinking them now. Another case of locking the empty stable.

The best lambs we have seen were on a piece of very fine Thousand-headed Kale, waist high. The shepherd reported a clean bill of health. The sheep had been on the Kale a fortnight, and appeared in excellent form to take to the Turnips adjoining, when they are ripe, but they keep on growing, and there is hardly a yellow leaf. With green food so unripe and watery, a good supply of dry food is most essential.

**A New Era.**

**S**TICK to your task and all will come right in the end. A homely and well-worn phrase is this, but it is also one which contains a great truism applicable to nations and individuals alike. Dark times may come—and they often will come—but in the face of all drawbacks the man who “faints not by the way,” but still presses onward, must inevitably achieve a fair amount of success. As a nation we have, during the last few years, been passing through a time of sore trial and great danger, for while our energies were concentrated on the stern conflicts of the battle field, our commercial competitors were forging ahead, by improving their methods and doing their best to capture our trade, both at home and abroad. In many instances they have unfortunately succeeded to a great extent, but signs have lately been apparent which go to show that a “new era has dawned upon the British people.” Recent trade returns show considerable improvement, and on all sides there are welcome evidences that, as a nation, we are “girding up our loins” to fight with might and main the competition which meets us at every turn; true there are hosts of difficulties before us, but if they are faced with an undaunted spirit and with strenuous endeavour, they will disperse like the mists of an autumn day.

Now let us turn to the realm of horticulture and see what is being done to keep pace with the needs of the times. Great efforts are undoubtedly being made to see that those who are beginning their career shall start with a sure foundation. With this object in view many educational establishments have sprung up, at which the teaching of both the theory and the practice of horticulture go hand in hand. The Royal Horticultural Society now

**R**EADERS are requested to send notices of Gardening Appointments or Notes of Horticultural Interest, intimations of Meetings, Queries, and all Articles for Publication, officially to “**THE EDITOR,**” at 12, Mitre Court Chambers, Fleet Street, London, E.C., and to no other person and to no other address.

affords the workers in its gardens good facilities for study, and for becoming well grounded in the theory of gardening, and no one will, I think, venture to say that the practical instruction given is not of the highest order. In the great national garden at Kew, and in many other public gardens, the valuable courses of lectures given are sufficient—without considering the many advantages for practical work—to cause great competition in filling the vacancies which occur. Many gardeners of olden times would have felt happy indeed could such advantages have been theirs, and when we also consider the reasonable rates at which good books can be obtained, no one, I think, can complain of the facilities which exist for acquiring knowledge, when compared with those which prevailed twenty or thirty years ago. The gardening instinct among the masses is also catered for, as suitable lessons are given by experts in connection with the educational schemes of the majority of County Councils, some of which even possess a good library of horticultural books which are circulated free. Let us also consider the practical side of the matter, because no amount of theory is of much value unless it is turned to practical account, and in some cases a sound theoretical knowledge has the effect of causing the possessor to ignore the necessity of doing good, practical work. Fortunately, however, such cases may be termed the exceptions, and under improved methods of training a knowledge of theory should prove an incentive to the performance of sound practical work, and when such conditions universally prevail, the new era will be in the full tide of prosperity.

On the practical side again, slowly yet surely—yes let us hope surely—the question of co-operation and cheap and rapid methods of disposing of perishable produce is being tackled with vigour, and with the advent of perfected and less expensive motors, outlying districts will be brought in direct communication with large towns. Those who are fully conversant with the matter know well what a stimulating effect this will have upon many neglected localities. That important phase of commercial horticulture, viz., “the fruit supply of these islands,” was dealt with at considerable length in the pages of the *Journal of Horticulture* some months ago, when it was shown beyond dispute that although much has been done during the last ten years, the work has not been done on sufficiently extensive lines. The season for planting has now arrived, when great efforts should be made to atone for past neglect by planting largely on suitable sites, where the soil is favourable. I say this for no sentimental reason, but because I know there is money to be made in the venture, and that, too, without any risk of losing the capital invested when knowledge and industry are brought to bear upon the work. There are plenty of small farms and estates offered for sale at the present time, and those who buy them at their present value, and invest in fruit culture on the right lines, will be taking a wise step. There are also many small holders who by the exercise of a little tact might come to an arrangement with their landlord which would make it worth their while to plant an acre or so. The help of all classes is wanted to greatly reduce the amount we annually pay for fruit which might be grown at home. Good trees can now be bought at reasonable prices, and if the fine stock in our nurseries which now awaits the “planters’ hands” could be cleared out entirely during the next five months, then a new era in fruit culture would indeed have dawned.—ONWARD.

## Economy.

(Continued from page 319.)

### The Fuel Bill.

Many a heated argument crops up over this question, and probably greater friction than arises from any other phase of garden economy. Not a few of the most generous patrons of gardening who spend ungrudgingly in other directions are apt to regard the firing bill as one which burns the biggest hole in their pockets. Let but an atom of coal or coke be visible on the ash heap, it is able to kindle a blaze which a hosepipe of eloquence may fail to extinguish. Much ado about nothing? Well, such an apparently trifling stumblingblock may be the means, have been in one instance, aided by a lamentable want of tact, of tripping up a good man and throwing him “out.” However, most men know the importance of not only avoiding evil, but of keeping from all appearance of it; and most men, too, have doubtless tried all ways and means to reduce this bill to its lowest consistent with safety and good work, so far as

existing appliances and local circumstances permit. Nevertheless, it is a question whether mechanical ingenuity has been exhausted in horticultural heating. Can those who have the most up-to-date system say that such system is the most perfect that could be devised? That heating engineers have arrived at the tether of their limits seems scarcely possible with the innovations and vast improvements continually being made in other directions, only inasmuch as they seem well content to leave us pretty much as we are. It remains, probably, for gardeners themselves to pave the way to perfection, as, indeed, gardeners have done to improvements; for instance, the late Mr. Stevens, of Trentham, working on the principle of the Cornish steam boiler, gave to the gardening world in the boiler named after that home of gardening one of the most powerful heat circulators we have. But few, unfortunately, have the opportunity and privilege of carrying their ideas into practical form.

The price of fuel, like the price of labour, is governed by circumstances outside a gardener’s control, and like that important item, too, if it cannot be wisely reduced it is always open to obtain the highest possible return for outlay. Oh! This means good stoking, some will say, which we know all about. It does; all that, and more. It is not surprising that after firing through a long winter and dreary spring a relief from labour and expenditure is sought by letting out the fires; yet, during sunless spells and low temperatures so oft prevailing at intervals throughout the summer season, shovels of fuel may save barrowloads later on in that most unsatisfactory endeavour to advance arrested growth in the plant section, or to obtain delayed maturation in the fruit department. It goes without saying that a volume might be written, as, indeed, volumes have been, on this subject of heating, entailing endless discussion by savants on the matter, all of which tends to show that finality has neither been reached nor unqualified satisfaction obtained. With one thought only over new departures the fuel bill is filed, viz., in suburban districts where gas is cheap, is there no opening for utilising it in horticultural heating? With present appliances, perhaps, not; but given copper boilers adapted for the purpose, why should not gas, which in many houses has abolished the kitchen fire for cooking purposes, be found as economical with all the added advantages of cleanliness and, practically, automatic working? “Oh! It wouldn’t answer,” is the abrupt dismissal by somebody of the matter. But, my dear somebody, my answer is “not proven”; and, probably, the dreaded gas bill would compare very favourably with the bugbear of a fuel bill; and, even in gardening, of two evils choose the least.

### Implements and Sundries Bill.

How blest is he who not only is able to do the right thing at the right time, but has a place for everything and everything in its place. Garden tools are not an unimportant item in first cost alone, but the vexation of spirit begotten of their abuse where the want of a system makes everybody’s tools nobody’s care amounts to more than can be estimated in figures, although they may be no inconsiderable adjunct to the bill. It is the means, too, of utterly demoralising good labourers and providing openings for excuse from bad or indifferent ones; and the nobody knows and nobody cares sort of principle prevailing is totally unworthy of that good gardening all aspire to, but some fail to reach. The force of example is one of the most powerful auxiliaries to law and order in garden government; hence, although guilty of repetition, a worthy Gloucestershire labourer, whose well worn spade, like his own character, as bright as silver, has long since been hung up in Time’s toolhouse for good and all, may be again exhumed, as he has been before, to point a moral and adorn a tale. In that model toolhouse of the long ago there they hung his spade, his fork, and all comprising his garden kit, conspicuous among the other sets of well kept tools by loving care bestowed on them after the bell had sounded Cease labour for the day. Such men as old Ephraim Gegg, all honour to his memory, and such tools—would there were more of them—do the best work. The moral is obvious. The method is perfect.

To-day, compared with auld lang syne, some of the most necessary garden sundries are represented by valuable goods contained in small parcels; for example, the virtues of a sackful of tobacco paper are now stored in a pint bottle of vaporising compound, and those who can compare the ancient, man-choking, plant burning system with the modern safe and certain method can regard it as but little short of a revolution. Still, there is no lack of grumbling about expense, and how necessary it is that strict economy should rule their use. A lock-up cupboard in the potting shed for not only the fumigating equipment, but for all similar sundries in frequent demand, which have the habit of smashing themselves, or the trick of vanishing altogether, is indispensable to thrifty management, and the garden office or storeroom where all heavier goods are tidily arranged is not less conducive to law and order than it is to economy.—QUIZ.

(To be concluded.)

**Sophro-Lælia × Heatonensis.**

An interesting and decidedly attractive bigener, of sharply defined form. The sepals are very pointed,  $2\frac{1}{2}$  in long, and tapering. The petals are oval acuminate, slightly sinuous at the apex, and, like the sepals, are rich dark crimson scarlet. The lip is long, narrow, and protrudes forward. Colour purple. A first-class certificate was awarded for it to Messrs. Charlesworth and Co., Heaton, Bradford, at the Royal Horticultural Society's meeting on October 7. The parentage is *Sophranitis grandiflora* and *Lælia purpurata*. Our illustration of a flower is from a drawing by Mr. Geo. Shayler.

**The Week's Cultural Notes.**

The flowers of *Dendrobium chrysanthum* being now over, it would naturally seem advisable to keep the plants dormant for a time; but, as a rule, they will not rest. Very often, in fact, the basal shoots are 2 in or 3 in in length by now, and the best thing to do is to place them in a good light, and keep them gently moving in the warm house through the winter. The production of roots from the stem must be anticipated, and new compost given to all that need it before this takes place. It is not a plant that likes too frequent disturbance at the root, and frequently fails to flower fairly afterwards.

A very beautiful plant now in flower is *Oncidium Jonesianum*. It belongs to the bulbous group, but its leaves, being large and vigorous, seem apparently to serve much the same purpose as pseudo-bulbs. At any rate, it is important to get each leaf or set of leaves well finished up in autumn, and as far as possible keep them quiet in winter. Although the flowers last a long time in good condition, healthy plants seemed to take no harm from their being left on, provided the roots are kept moist. When the flowers fade keep the plants in a good light, a rather cooler position, and just moist at the roots. Diminish the water supply as winter comes on, until for a week or two in the darkest days they may be kept perfectly dry.

The little repotting remaining to be done should be attended to without further delay. It will be principally devoted to autumn flowering *Cattleyas* and late plants of earlier blooming species that root at this season. The showy and beautiful *C. Bowringiana*, for instance, usually sends out a new tier of roots now or shortly, and should the compost be in a bad condition, it is better to risk the disturbance and repot now, even before flowering, than to allow fresh, young, healthy roots to enter it. The same applies to *C. labiata*, *C. Gaskelliana*, *C. gigas*, *Lælia elegans*, and *crispa*; in short, any that now show a disposition to root.

In the cool house flower spikes are rapidly advancing, and great care and watchfulness are needed to prevent the attacks of insects. Slugs and small snails are particularly fond of those of *Oncidium tigrinum*, *Odontoglossums* of the *crispum* and similar types, and others, and only by constant care can their efforts to get at them be thwarted. Search for them at night with a lantern. Trap them in hollowed out Potatoes and under Lettuce leaves. Place a little cotton wool around the base of the bulbs carrying the spikes, and when valuable varieties are concerned place these on an inverted pot in the centre of a flat vessel of water, carefully noting that no part of the plant makes a bridge over which the insects may travel.—H. R. R.

**Growing Bulbs.**

There are more ways of growing bulbs for our rooms otherwise than in soil, and at the same time good results obtained. Hyacinths, for instance, do exceedingly well if grown in moss. Fill a flower-pot half full, pressing it very tight, then place the bulb in the centre, covering it entirely and pressing the moss tightly round it. Keep it damp by standing the pot in a saucer of water and keeping it in a dark place for six weeks, after which, bringing it gradually to the light. I have seen some grand spikes obtained in this way. Narcissus also do well when grown like this and last equally well.

One of the prettiest baskets I ever saw was one filled with Snowdrops growing in Sphagnum moss. Care, however, should be taken to obtain this in a living, fresh state, as the green colour of the moss enhances the beauty of these early spring favourites. The bulbs should be planted thickly, which bloom freely and come much cleaner than when grown in soil; and I have also found them last much longer if kept cool. *Scilla Siberica* also thrives well in moss, and if planted with the Snowdrops has a very pleasing effect. In growing bulbs in this way it is essential not to force them, or they are apt to come blind. Hyacinths, especially, very often fail through being kept too warm in the early stages of growth. The cooler they are kept the better and more

certain the bloom. Often-times complaints are made that the Hyacinths have only an inch or so of bloom, and gradually die off. This is invariably caused by being brought to the light before the roots have grown sufficiently strong, and by being placed in a warm room, causing the flower spike to appear before the leaves are any way developed. There is another cause for failures with bulbs, and that is in obtaining them so very late in the season. Many people delay buying their bulbs until the end of November, and even as late as the middle of December, which is far too late in order to obtain good results, and very often no results at all. The bulbs by this time are dried out, and as often as not only throwing exceedingly poor flowers, and sometimes none at all, causing disappointment to the grower and a bad opinion of the bulb

**Sophro-Lælia × Heatonensis.**

merchant. October is undoubtedly the best month for all bulbs except, of course, the early forcing varieties, which should be potted as soon as received from the bulb farms. There are differences of opinion as to changing the water of Hyacinths grown in glasses. I notice in one gardening paper a correspondent advises changing it at least twice a week. This, I think, is a great deal too often. If a lump of charcoal is placed in each glass I hardly think the water need be changed at all. Certainly not oftener than twice during the growing season. It should, however, be replenished as it evaporates. Supports should always be used for the spikes to avoid them falling over and breaking. Spraying with Hughes' Aphicide is also beneficial to the bloom when expanding.—H. KITLEY.

**Liverpool and the Importation of Canadian Fruit.**

A large consignment of exceptionally choice and well developed specimens of Canadian Apples has just been received by Sir Alfred L. Jones (Messrs. Elder, Dempster, and Co.). This shipment has been specially forwarded to Sir Alfred by a Minister of the Canadian Government, with the object of demonstrating the rapid advance that the Dominion is making in the cultivation of choice fruits. The following varieties are included in this shipment:—Twenty-Ounce Pippin, Northern Spy, Ribston Pippin, Blenheim Pippin, Emperor Alexander, North Star, Gravenstein, and Wealthy, &c. These extraordinarily fine Apples have been entrusted by Sir Alfred Jones to Mr. Thomas Dowd, fruiterer, of Moorfields, by whom they will be exhibited during the next few days.

# NOTES & NOTICES

## Irish Wild Fruit.

Just now the business of gathering Blackberries and Crab-apples for the English markets is being vigorously carried on in the South of Ireland. A great demand exists for these articles owing to the scarcity in the fruit supply in this country. Tons of Blackberries and Crabs are being picked every day by the gatherers, who scour the hedges all over the country. No doubt later on Crab-apple jelly and Blackberry jam, "Irish brand," will be very plentiful and popular in England.

## Irish Fruit Preservation.

Under the auspices of the Department of Agriculture and Technical Instruction for Ireland, and with the view of promoting a fruit industry in that country, a very large fruit show was last week held in the concert hall of the Cork International Exhibition. Splendid samples of Irish grown fruits were sent from every county, in competition for valuable prizes offered by the department. A section was set apart for preserved fruits of Irish growth, and Mr. J. E. Austin, of Kingston-on-Thames, had the honour of being sole judge of these exhibits.

## Royal Horticultural Society.

The next fruit and flower show of the Royal Horticultural Society will be held on Tuesday, November 4, in the Drill Hall, Buckingham Gate, Westminster, 1 to 4 p.m. A lecture on "The Dietetic Values of our Common Vegetables" will be given at 3 o'clock by the Rev. Prof. G. Henslow, M.A., V.M.H. \* \* At a general meeting of the Society held on Tuesday, October 21, thirty new Fellows were elected, amongst them being Lady Owen Roberts, the Hon. Mrs. Wood, Col. Henry Moore, and Col. F. B. P. White, making a total of one thousand and five elected since the beginning of the present year.

## Newport (Mon.) Gardeners' Association.

The usual meeting of the above society was held on Wednesday, October 22, when Mr. W. E. Lewis read a paper on "The Culture of the Eucharis." Mr. Lewis, who is a successful grower of the Eucharis, gave a very interesting account of his manner of treatment, giving instructions as to potting, soil, temperature, &c., also that it required most careful watering, and not to overpot, once in four or five years being often enough after they are in 10in or 11in pots. Mr. Lewis also gave instructions as to shading, resting, &c., and bringing them into bloom at certain specified dates, as they are required. A good discussion followed, in which Messrs. Kenward, Harris, Duff, Jones, Powell, Daniels, and Reece took part, and many questions were asked. Mr. F. S. Daniels presided over a good attendance of members.—J. P.

## London Dahlia Union.

The undersigned write as follows:—"We have the pleasure to invite your attendance at a meeting of supporters of the above to take place at the Royal Aquarium, Westminster, on Tuesday, November 4 (the first day of the Great Exhibition of the National Chrysanthemum Society), at four o'clock p.m., in the Gallery Dining-room. A statement of receipts and expenditure duly audited will be submitted, and a report from the chairman and secretary to the effect that they have arranged with the directors of the London Exhibitions, Limited, Earl's Court, West Kensington, for the exhibition of the London Dahlia Union to be held in the Prince's Hall of the Exhibition, on Wednesday and Thursday of the third week in September. The directors of the Earl's Court Exhibition have met the suggestions of your chairman and secretary in the most liberal manner, and it is certain that a very fine exhibition may be anticipated. The London Dahlia Union has done much to popularise the Dahlia among all classes by holding exhibitions of a high character in a place of popular entertainment, and thus have been the means of interesting thousands in the Dahlia and inducing many to cultivate and exhibit it. Requesting the favour of your presence and also your support of the union in maintaining its most successful career.—JOHN GREEN, Chairman; RICHARD DEAN, Secretary.

## Chrysanthemums at Westbury.

In his notes on Chrysanthemum maximum and latifolium varieties, as seen at Messrs. Isaac House and Son's nursery, near Bristol, our correspondent on page 382 last week, named Margaret Marwood as one of the freest flowering and best sorts. This is incorrect, and indeed there are far better varieties than the one named. It might well be omitted from collections.

## A Unique Society.

The employés of Thomas Meehan and Sons, Inc., Germantown, Pa., U.S.A., who for some time have been studying botany at the nursery office, have formally organised a horticultural society. Constitution and bye-laws were drawn up and adopted. The society will be known as the Thomas Meehan Horticultural Society, so named in honour of the late Thomas Meehan, one of the most eminent botanists of his day.

## A Weeping Ash.

I enclose photos showing winter and summer state of one of our two trees of Weeping Ash. Being the largest specimens which I am acquainted with, I thought probably your readers might be interested in them. I have just measured the height of the one illustrated, which is 40ft high; spread of branches, 70ft; bole at 4ft from the ground, 8ft in circumference; age, about 120 years. One peculiarity about these trees is their quickness in putting on their summer garb and assuming such denseness of foliage in a very short time. The same quickness is observed in casting their foliage; they are now perfectly green, and at the first frost we get it will in a few days denude them of all foliage. The photograph was taken by Mr. Fairbairn of Nostell.—J. EASTER, Nostell Priory Gardens.

## Patent Potato Digger Trial.

The Battersby Patent Potato Digger and Gatherer is a very handy machine, which, on trial on the 24th on Lord Wenlock's Menagerie Farm at Escrick, dug up and stored in hampers about a cart-load and a half of Potatoes in four and a half minutes. It marks a distinct advance upon the ordinary digger. The advantage the new machine has over the ordinary diggers is that it shoots the Potatoes into hampers, which can be easily emptied into a cart, whilst the others, scattering them over the surface of the land, require a large number of followers.

## Potato Growing Experiments.

Mr. W. L. Hutton, the respected proprietor of the "Ormskirk Advertiser," offers special prizes at the Liverpool Fruit and Root Show for the newer varieties of Potatoes. The following season they are cultivated in the best possible manner with a view to their being recorded for the benefit of the public at large. Ormskirk, Lathom, and Aughton (the trials taking place at the latter place) are amongst the best centres in England for Potato growing, so that the notes of trials just published will be of much interest to all readers, and more especially to those who market them, and for which more particularly the trials are conducted. Mr. Henry Jenkinson has had sole charge during the season, the weights being as follows:—

|                             | Weight of seed. | Weight produced. |        |           |
|-----------------------------|-----------------|------------------|--------|-----------|
|                             |                 | Large.           | Small. | Diseased. |
|                             | lbs.            | lbs.             | lbs.   | lbs.      |
| Empire .. .. .              | 2               | 9                | 1      | 0         |
| Pioneer .. .. .             | 3               | 92               | 5      | 1         |
| General Buller .. .. .      | 2½              | 18               | 2      | 3         |
| Uncle Tom .. .. .           | 2½              | 6                | 1      | 0         |
| Empire .. .. .              | 2½              | 38               | 2      | 0         |
| Duchess of Cornwall .. .. . | 2½              | 61               | 3      | 1         |
| Pioneer .. .. .             | 2½              | 79               | 3      | 1         |
| Royal Kidney .. .. .        | 2               | 53               | 2      | 0         |
| Charles Fidler .. .. .      | 2½              | 46               | 6      | 0         |

From the above it will be seen that several lots of certain kinds were planted, Mr. Hutton receiving them from the show and undertaking their planting. Pioneer leads the way, followed by Charles Fidler and Duchess of Cornwall, each variety being of good table quality.—R. P. R.

**Streptocarpi from Feltham.**

Messrs. J. Veitch and Sons, Limited, of the Royal Exotic Nursery, Chelsea, S.W., send a selection of their winter flowering Streptocarpi. The scapes bear half a dozen flowers in many of the varieties, the blooms resembling in shape those of the Achimenes. The variation in colour ranges from spotless white to deep blue and maroon, having red, amaranth, crimson cerise, blush and pink shades within these limits, which makes these plants very valuable for the winter season. They respond to good culture and flower freely. The Streptocarpi (Streptocarpus) are now in full bloom at Messrs. Veitch's Feltham branch, and promise to remain so over Christmas; in fact, there is little difficulty in having blooms continuously for nine months in the year.

**Cardiff Gardeners' Association.**

On Tuesday, October 21, a meeting took place at the Grand Hotel, when Mr. C. E. Collier presided over a large gathering of members. Mr. R. W. Treseder, F.R.H.S., delivered a highly interesting lecture entitled, "Budding, Grafting, and Layering." Several specimens of buds and grafts were brought to the meeting, which the lecturer used by way of making his subjects more easily understood. After speaking for over an hour, the debate was very lively and interesting in the extreme.

A very cordial vote of thanks was accorded Mr. Treseder for his splendid lecture, to which he suitably responded. Five new vice-presidents were enrolled and several ordinary members.—J. JULIAN.

**A Liverpool Improvement.**

The barricades are up, and an army of workmen now occupy the space of ground where some few years ago stood St. John's Church, and which after its demolition was converted into an open space for the people. Since then a more ambitious scheme has suggested itself and been passed by the City Council, and in the near future there will rise—with the magnificent St. George's Hall as a background—a splendid terrace garden, with sufficient space to accommodate the statues of Liverpool's worthies for many years to come. The cost is great, but with the fine classical building aforementioned, the Walker Art Gallery, Pieter Lecture Hall, Museum, and the grand Technical School lately completed, all alongside, it is only fitting that the Parks and Gardens Committee, of which Alderman J. Ball is so conspicuous a chairman, should see that horticulture played its beneficent part. In so central a position, the improvement should be gladly appreciated.—R. P. R.

**Hull Horticulturists.**

The annual general meeting of the Hull and District Horticultural Association was held in the Oddfellows' Hall, Charlotte Street, on October 21. In presenting the annual report, the general secretary (Mr. J. F. Posthill) said that during the half-year ending October 21 the ordinary monthly meetings had been well attended, and the discussions thereat had been very profitable to the members. The committee wished to publicly acknowledge the services of Messrs. F. Judson (chairman), G. Coates, J. O'Donoghue, and A. C. Tattersall during the past session. The annual exhibition was held on September 10 and 11, and, though there was a deficit on the working, they had every reason to congratulate themselves on having organised such an attractive show. The exhibits were consistently good, and in the opinion of competent judges the show was the best that had been held in Hull for many years. The numbers of exhibits and entries were respectively 15 and 213 in excess of those at this year's Yorkshire Show. There was a considerable increase in the number of members. Six months ago the hon. members numbered 16, and the ordinary members 123; but they began the new session with 31 hon. members and 157 ordinary members. The report was unanimously adopted. Some of the officers elected were: Chairman, Councillor Raine; vice-chairman, Mr. J. T. Barker; hon. treasurer, Mr. G. H. Horsfield; hon. secretary, Mr. J. F. Posthill; auditors, Messrs. W. E. Sanderson and Rymer; hon. librarian, Mr. H. Franklin; trustees, Messrs. R. Arksey, W. Pockley, T. Jaggard, and W. Stephenson. It was decided to increase the subscription of membership from 2s. to 2s. 6d. Several minor alterations in the rules of the association were decided upon.

**The Journal's Rose Analysis.**

The annual Rose analysis prepared for the *Journal of Horticulture* by Mr. Edward Mawley, will be published about the second week in November. This note is intended as an answer to numerous inquiries which have been made.

**National Chrysanthemum Society—Classification Committee.**

At a meeting of this Committee, held at the Royal Aquarium on October 7, Mr. Norman Davis was elected chairman of the Committee. It was resolved that the following two varieties, Lily Mountford and Hilda Chamberlain, be bracketed as synonymous in the Society's list of too-much-alike Japanese varieties. That the following be bracketed as synonymous in the list of early flowering varieties: Harvest Home and Cranford Beauty. That the Pompon varieties, Martinmas, La Vierge, and Vesuve, be transferred from the early flowering Pompon section to the early large flowering section. It was further resolved that the heading in the Society's catalogue, "Japanese Early Varieties," be altered to "Large Flowering Early Varieties," so as to include all types except Pompoms. That a new class be added to the catalogue now in course of compilation to embrace market and general decorative varieties other than early flowering.

**Birmingham Gardeners' Association.**

As we notified in the *Journal of Horticulture*, Mr. Lewis Castle, of the Experimental Gardens, Ridgmont, was met by a large assemblage of the members on the 20th inst. to listen to his discourse on "The Evolution and Improvement of Fruit," and in this respect it is hardly necessary to remark they were not disappointed, prepared as they also were from previous experiences of Mr. Castle's ability to deal specially with the subject in question. The subject in hand was ably dealt with, and illustrated with a numerous variety of Apples, Pears, Damsons, Crabs, &c. The lecture led to an animated discussion, in which the chairman (Mr. W. B. Latham), Messrs. W. Spinks, W. Gardiner, R. J. Hamill, C. R. Bick, and Walter Jones generally took part. A hearty vote of thanks was awarded to Mr. Castle. There was a good competition for the prizes offered by the committee for bunches of hardy border Chrysanthemums, the winners being Mr. R. J. Hamill; Mr. W. Hiron, gardener to Geo. Jackson, Esq., The Grange, Moseley; and Mr. J. Sceaney, Harborne, as in their order named. Messrs. Simpson and Son, Birmingham, were awarded a special certificate for a fine and comprehensive collection of hardy Chrysanthemums.

**Notes from Aberdeen.**

Taking advantage of the periodical generosity of the railway company in their reduction of fares, I recently had the pleasure of spending an enjoyable holiday in Aberdeen. It was dark on leaving Edinburgh, but by the time we reached Stirling the sun was beginning to break on the higher lands. Harvesting was general; green crops impressed us unfavourably. Turnips are in many cases a poor crop, and Potatoes showed the too well known signs of disease. From time to time thriving plantations of hardwoods and Conifers arrested our attention, and from their vigorous growth the season has not been adverse to them.

One striking feature of the landscape was disappointingly absent, and that is autumnal colouration of foliage; everywhere exhibited the dull, sombre green, unless where withered and blackened from the effects of the recent storm.

The first visit at Aberdeen was to the nurseries of Messrs. Cocker and Sons. Sunnypark, where the larger portion of the glass houses are situated, was the portion first visited. One large structure contained Liliiums in great variety, and early flowering Chrysanthemums also made a gorgeous display, notwithstanding the fact that large quantities were that morning cut for the firm's shop in Union Street, where the floral work is executed. Another house containing cool Orchids was worthy of note, the plants being in fine health, and the quantity of flowers contributed by the *Cœlogyne cristata*'s must be enormous. In a cool propagating house I noted cuttings of the newer varieties of early flowering Chrysanthemums, many of which are of Messrs. Cocker's own raising. The outdoor part of this nursery is largely devoted to the raising of seedling herbaceous plants,

*Rubus deliciosus.* (Referred to on page 409.)

with a representative collection of forest trees. This department of the nursery was at one time the chief trade, but is not now given so much attention.

From Sunnypark we proceeded to the Morningfield Nursery, which is devoted to the cultivation of herbaceous plants and Roses. Here we had the good fortune to be taken in hand by Mr. Cocker, who received us cordially, and did all in his power to make our visit as instructive and enjoyable as possible. This ground has of late years been much disturbed by the ubiquitous builder, resulting in their having to seek pastures new, and the firm has secured a tract of land sixty-two acres in extent, on the estate of Springhill, about a mile further on. An example of the inconvenience to which a nurseryman is sometimes put in this respect was furnished by the following. A portion of land containing Rose stocks with dormant buds was feued for building last autumn, and these had of course to be transplanted to another part, which was well manured at planting. Late in spring this latter portion was also feued, with the result that another transplantation had to be made, without compensation for loss of manure, labour, &c. The bulk of herbaceous plants from this ground will be moved to Springhill this winter, and when one considers the amount of plants to be treated, this is no small undertaking.

In a cool, shady part was noted a full collection of Primulas, among which was a fine lot of *P. nivalis*, a species now rather scarce. *Ourisia coccinea*, in a bed containing fine strong plants, still threw a few belated panicles of brilliant red; whilst a carpet of *Acæna microphylla glauca*, close by, suggested its adaptability as a carpet bedder. In frames were Violas in great variety, seedling Roses, *Eremurus*, and many other subjects. *Heuchera sanguinea grandiflora*, having a large spike, is valuable for cutting. *Helianthus*, *Montbretias*, *Phloxes*, *Liliums*, *Eryngiums*, *Erigerons*, *Gladioli*, *Chrysanthemums*, are all largely cultivated. Hybridisation and crossing is being pursued by those in charge.

Conifers thrive grandly in the nursery of Messrs. Ben Reid and Sons, and many of the variegated varieties of the Cypress tribe rival those from the most favoured parts of the Continent. Messrs. Smith and Son's nursery at Burnside contains a good general collection of nursery stock. Seedling forest trees appear to be their speciality. Scot's Pine, from home-saved seed, was a particularly fine crop, both at one year and two years of age.—W.

## Pears for Profit.

During recent years a great amount of attention has been drawn to the necessity for planting Apples on a large scale in this country, and when we hear of the vast amount of planting which is being done in other lands for the purpose of supplying us with Apples, it is evident that in Britain far too little has been accomplished. Pears, however, ought to claim a considerable amount of attention, and I fear they have been somewhat neglected of late. In selecting sites and localities for Pear culture, there is a less wide range than in the case of Apples, as it is necessary that cold, bleak districts should be avoided, even when the soil is suitable, because as the trees flower so early the danger from frost is great. There are, however, plenty of warm districts in which Pear culture might be made a very profitable industry. An ideal soil for Pears may be described as rather deep loam, resting on a strata of loose stones. And for strong growing varieties, such as Pitmaston Duchess and Beurré d'Amanlis, if the loam is inclined to be stiff, so much the better. One may often find a deep loamy soil resting on gravel or clay. In the former instance, satisfactory results are invariably

obtained, and in the latter case effective draining, and growing a farm or garden crop on the land for a year before the trees are planted, will bring it into splendid condition for Pear growing. Shallow or sandy soils should always be avoided, but loamy soils intermixed throughout with stones answer well. And I have seen Pears thriving splendidly in very stony soil, when the intermixed particles of earth were somewhat stiff.

It is well known that Pears need a great amount of potash, and as stiff soils yield a large percentage of this valuable constituent, it probably accounts for the success of growers who have a rather stiff soil. I am afraid the spring frosts are often blamed for a poor crop of fruit when they have had but little to do with the matter. For several years I have watched numbers of trees closely when in flower, and in some cases, although there were no frosts to injure the blossom, yet the bulk of the fruits dropped after having apparently set well, and although the soil was moist enough around the roots. This I am inclined to attribute to a deficiency of potash, and during the following autumn I intend to try the effect of a good dressing of kainit. I know in some instances long spells of very cold weather just after the fruit is set will cause young Pears to drop, even after fertilisation has been perfected, and I found that to be the case last year; but in seasons when the weather is in all respects favourable, I have noticed a similar wholesale dropping of the young fruits. If the real cause for this state of affairs can be with certainty discovered, a great impetus will be given to Pear culture.

In preparing the soil for planting the same thorough preparation should be given as that so often recommended for Apples, as without good work in this respect satisfactory results can neither be expected nor obtained. In arranging the trees I prefer to plant the standards or pyramids on the Pear stock in blocks by themselves, and those on the Quince stock in another block, instead of intermixing them, as the taller growing trees after a few years shade the dwarfs too much, and in our climate every advantage ought to be taken of sunshine.

A suitable distance apart for planting trees on the Pear stock is 30ft, and for those on the Quince from 10ft to 12ft. The Chalk Pear, which grows quickly and bears well, is excellent for planting around the outside to form a screen. In selecting varieties for market purposes a long list is not required.

The following may be thoroughly relied upon. For standards and large pyramids: Doyenné Summer, Beurré Giffard, Lammas, Jargonelle, Beacon, Hesse, Pitmaston Duchess, Williams' Bon Chrétien, Aston Town, Fertility, Eyewood, and Doyenné Boussoch. For stewing: Catillac, Verulam, and Beurré Clairgeau. Trees on the Quince stock: Souvenir du Congrès, Beurré d'Amanlis, Marie Louise d'Uccle, Beurré Bosc, Beurré Jean Van Geert, Doyenné Boussoch, Doyenné du Comice, Durondeau, Fondante de Thriot, Marguerite Marillat, Pitmaston Duchess, Williams',

and Triomphe de Vienne. The soil is this season generally in excellent condition for planting, and no time in the whole year is more suitable for carrying out such work.—WARWICK.

## Notes on the Crops.

Writing at the middle of October, one thing that strikes me is the intense greenness of everything. It is true that the Virginian Creeper on the wall has changed to a rich red tint, and the Chestnuts and a few other trees have assumed their golden mantles; but, as a rule, the changes, as yet, are slight. October this year is the month of flowers generally, and Roses in particular. According to every established rule, the queen is at her best in June and July, but never has the garden been richer in Roses. Nor is this glorious display of October Rose blooms confined to one section, for while the Hybrid Perpetuals and Teas in the garden seem to be contesting with each other to see which is the best, the old Gloire de Dijon on the house wall is bearing a full second crop of flowers, and this morning (October 16) I cut a charming Maréchal Niel.

Near to the Roses are the Dahlias, and in some places Jack Frost has blackened the leaves. Year by year the Dahlia seems to grow more popular. We owe a debt of gratitude to the raisers of Cactus Dahlias, but too much is thought of the flower and not enough of the habit of the plant. The footstalks of the blooms are not long enough or strong enough to support them in an erect position, and the new varieties in the garden are disappointing. I am also inclined to ask, Do new Dahlias last? Each year they come in ever increasing numbers to win the awards from the committees who sit in judgment over them. Then they go forth to the world and the gardens of growers, and little more is heard of them, because next year the Dahlia world is again taken up with the novelties. It would seem, then, that new Dahlias, like new Chrysanthemums, are not lasting institutions, and after a few years they slip away and are lost in insignificance.

October is the month of curiosities, and every morning almost the daily paper has odd little paragraphs telling about someone picking a dish of Strawberries, or a Pear tree bearing matured fruit and blossoms at the same time. The gardeners are used to the oddities of Dame Nature, and take little notice of them; but everybody is not, and if a little precocious Primrose on the bank sees fit to bear a few flowers this side of Christmas, sure enough some person sees the wonder of it, and sends forth the remarkable piece of information to the world through the medium of Fleet Street.

The harvest of the kitchen garden is not so satisfactory as we should like it to be, because the Potatoes are badly blighted. Most of the growers, in my district of Kent at any rate, are hard hit by the disease, and forecasts are being made that the precious tubers will be dear before the winter is over. During the past few weeks we have been busy lifting the late crop, and of all garden operations that can be fascinating or disappointing, according to circumstances, commend me to Potato digging. When the crop is good, and big sound tubers roll out as each root is lifted, your heart goes into the work; it ceases to be tiring, and backache is forgotten in the intense satisfaction that prevails. As a grower you feel that you have accomplished something, and that a share of the credit belongs to yourself; but under other circumstances all is different. When the crop is light and the lifting of the majority of the roots display three or four tubers something bigger than marbles, the most cheerful disposition grows despondent, and when in addition to this you find that nearly every respectable Potato is affected by disease, then it would require the philosophy of a Mark Tapley to keep cheerful, and, as that eminent authority would put it, there would be some credit in doing it.

The blackest mark, however, appears against Potatoes, and we have sufficient of other vegetables to stand a siege. Onions are good, and all through this summer I have never seen the trace of a maggot, which says something for the season, bad as it may have been in other respects. As I turn my thoughts from the Potatoes and survey the beds of Carrots, Parsnips, and Beet, my heart grows cheerful, and, wonder of wonders! we have been able to grow Turnips all through this summer, without continual recourse to lime, soot, paraffin, and other things that the hard-backed little "flea" takes so little notice of. All through last summer Turnips were a dead letter, but it has not been so this year, and in a healthy looking bed now we have a large stock to draw upon. Then what a season it has been for Peas, both early, midseason, and late, proving beyond doubt that the chief requisite of the Green Pea is moisture. Scarlet Runners were late in coming in, but they are plentiful still, and will be till frosts make their appearance. Celery has grown freely from the outset, and clear of maggot. We

have begun to dig, and the hearts are of that sweet nutty flavour which one rarely gets when the plants have sustained checks.

I have one dismal story to tell, however, and it relates to outdoor Tomatoes. The fact is the season has not suited them; the days have been too dull, and the nights too cold. None except strong early planted specimens have ripened their fruit outdoors, and for the most part the green fruits have hung on the plants till they fell prey to the ravages of disease. We have been taught a lesson this year, to the effect that unless Nature is liberal in the way of warmth and sunshine Tomatoes are not an outdoor crop.

Rain has been the grumble of most people during the summer, and yet at the middle of October we learn from the authorities that the rainfall has been less than the average, and people are crying out about being short of water. The fact is we have not had a real wet summer for so long that we have forgotten what they are like.—H.

## A Corsican Garden.

In many ways the trite proverbs relating to Naples and Nikko might with much aptitude be applied to that lovely garden town, Ajaccio, in La Belle Corsica, with this distinguishing difference, however, the climate is far finer than either. Save for perhaps two months at midsummer the remaining ten you may bask in a glorious yet refreshing sunshine among fragrant flowers and shrubs and cooling fruits. Indeed, such are ever present the entire winter through, the latest Grapes and Figs joining hands, as it were, with the golden Apples of the Hesperides, and forming an elegant and becoming ornament not only on terraced walks and cultivated orchards, but right throughout the main boulevards of this mid-Mediterranean palmy "citta."

I use the word advisedly, for, though French by government, the natives are Italian in speech, mien, and habit, though needless to say they prefer their title of Corsican to either other designation. In point of fact, however, they are partly descended from the Genoese settlers and partly are of Arab or Berber origin. They possess, too, a good deal of the *dolce far niente* character of the Neapolitan, the male element at least, for the women I remarked as peculiarly diligent, meeting them of an afternoon returning from work in the vineyards and Olive yards in groups together, walking briskly along with bundles of brushwood upon their heads, while those having "their daily round and common task" in the town might be seen, morning, noon, and night, doing their washing at the various watercourses, or marching erect, with huge water-pots and other weights, and bearing themselves with the gait and comeliness of the superb carriage of the women of Capri.

The almost entire absence of wind, such as a tramontane or mistral, and a total immunity from dust by reason of the nature of the soil, is not only a great boon to the sojourner at Ajaccio, but possibly is of considerable utility in producing the wealth of luxuriance which obtains in the vegetable kingdom there. Situate on the hill slopes, neither very steep nor yet on any even ground, but upon graceful undulating inclines, there stands a lovely little white château, framed as it were in a rich setting of varying hues of green, as seen from the vale below. Approaching nearer, the direct vista reveals mid its deep, handsome foliage golden balls in considerable profusion here and there in different directions. Closer still will be discerned their definite positions, as also on the outskirts a vineyard here and there, and glades of the soft-toned evergreen Olive, now (at the time of the writer's visit) in course of having its small black produce garnered in for its annual crop. And finally, as we reach the terraces, our close gaze is brought to revel in garlands of twining Tea Roses, purple and red flowering creepers, white Periwinkle peeping in and out among the bushes, and the exquisite close-growing, little blood-coloured bloom which appears largely in most Corsican gardens, but the name of which has escaped my memory. Besides much that took the fancy I was a good deal impressed by the varieties of Genista. The common yellow kind was broadcast over hill and dale, but here in this cultivated oasis on the hillside there were beautiful kinds of a white and scarlet colour. Then, too, the red Aloe in full bloom was very handsome

and striking, while immense patches of the two sweetest and most admired of the Narcissus tribe were very much in evidence. The Pepper tree also played a somewhat prominent part in this as in other gardens that I had the privilege of seeing, and attains in this sympathetic climate considerable proportions. The Prickly Pear, though to some extent a nuisance and a weed, is yet valuable all round these parts as in other indigenous countries, not only for the excellent hedges it forms, but also as regards a superior sort, at any rate, for its fruit, which the natives are usually very fond of, and though insipid for the most part, is yet presumably a wholesome and nourishing product.

An aqueduct of crystal water flowing direct from the mountains supplies an inexhaustible and ever-ready source for irrigating this charming semi-tropical garden. Many different kinds of handsome Palms, several of the Banana genus, groups of elegant Bamboos, with specimens of the Indiarubber tree and the exquisite Mimosa in the fullest flower and of noble proportions, afforded a feast liberal enough to gratify the taste of the most exorbitant of Nature's gourmands. But there was much beside and galore in variety even at this, the most dead season of the whole year. Thus a most showy and profusely scented flower was that of the tall, towering plant of the Guccorine, with spurs absolutely crowded with its large petalled orange flower, and apparently preceeding the foliage. Of Oranges several kinds of the ordinary shape were grown, which for the most part were exceedingly juicy and of admirable sweetness and flavour, while in addition the Mandarin, Tangerine, and Jaffa were each cultivated. The Almond, which comes to the greatest perfection here, was just appearing in bloom, while the Peach, Cherry, and Apricot, also largely grown, were seen plumping up their buds with an appearance of a bountiful season's crop. The soil being of decomposed granite entirely, while suited to some growths, particularly the Mimosa, is but a poor bed for many of the smaller products, whether of fruit, flower, or vegetable, and herein my friend, the kindly host and owner of this delightful residence, labours under considerable difficulties. Perhaps his fairest and most beautiful flower is his own lovely little maiden daughter of some eight summers—a perfect dream of sweetness and innocence, mingling her baby voice and lithe form with the pure delights of Nature's treasures.

I must in conclusion refer to the interesting series of plants and trees a little higher than the level of this fairy spot on the hill slopes. The line of growths in Corsica is very distinct, thus leaving behind the Olive, Plane, Eucalyptus, Orange, and Almond, we find the Holm Oak, with now and then a Cedar asserting a very large dominion, having as associates among smaller products boundless expanses of Arbutus, striking enough whether in the full glory of its large red berry or in its bridal array of white bloom, the bushes being thus variously decorated with either ornament. A tier higher the gnarled and fantastic Chestnut comes upon the scene with plenteous patches of our own so-called Christmas Rose or Hellebore helping to form Nature's varied carpet, while masses of pink and white giant Heather, rising in height to fully 6ft in places, and interspersed with the wild Mint, of a like prodigious growth, afford in their season of flowering a gorgeous but somewhat impenetrable verdure.

Still upward, and now well among the mountains we meet the Pine taking almost sole possession, with little else than scrub and certain plants and flowers, while the utmost limit is reached and found to contain the beautiful and symmetrical Beech. Not quite at so exalted a height, but yet at a very considerable altitude, and right upon the summit of a lower range of mountains stands an exceedingly remarkable building. A former duke, Pozzo di Borgo,\* in a true Corsican spirit of vendetta against Napoleon, caused to be conveyed across sea and land and up these formidable and impregnable heights a very large portion of the Tuileries itself, and formed his château therefrom. It stands out in all directions as a remarkable and unique landmark, fulfilling literally, though not in the way intended, a father's will that a certain huge sum should be expended in erecting buildings in the island, and having the most superb views both land and seaward, seeming to be a kind of sentinel guarding the Isle of Unrest, but destined doubtless when its own day and generation be past to become itself but a ruin and desolation, for "sic transit gloria mundi."—J. A. CARNEGIE-CHEALES.

\* In 1791, when Corsica was rent with the turmoil of the French Revolution, Napoleon Bonaparte and his partisans—all needy adventurers—figured as French red-republicans or terrorists in Ajaccio, while the di Borgos represented the respectable Corsican party. Pozzo was nearly assassinated by the French faction, and after Bonaparte wantonly shot down the people coming out of church the Bonapartes had their house burned and were chased out of the island utterly discredited, ruined, and destitute. The feud lasted twenty-five years. Later Bonaparte tried to catch Pozzo and shoot him, and Pozzo intrigued at all the European courts raising up enemies against the French Empire. He succeeded, for he saw Bonaparte deported to St. Helena. He subsequently represented Russia at the English and French Courts, and died very distinguished some twenty-five years after his adversary. In Corsica the di Borgos are regarded as patriots, while the Bonapartes are considered in some sense as turcoats.

## Ornamental Sylviculture.

The practice of forestry has exercised the minds of British landowners, their agents, and their foresters to a greater extent during the last few years than at any previous time. Old systems of forestry practice are being closely criticised and subjected to frequent comparisons, and even a book, "The New Forestry," was written by a leading British practitioner and published in this country in 1900, to advocate another method of treatment here. In the course of a long letter to our contemporary, "The North British Agriculturist," Mr. Jas. Farquharson, of Inverkip, Renfrew, seeks partly to oppose the new forestry, and some of his remarks on ornamental forestry are worthy of being reproduced here.

"British forestry has, at least, three distinct features of utility in so far as relates to the requirements of British tastes and ideas, and may be classed under these three heads—ornamental woods, sporting woods, and commercial woods, which marks the line of difference between British and foreign forestry. The ornamental part of sylviculture is that part which embellishes the valley and upland, the nobleman's park and mansion, sometimes picturesquely placed and sometimes otherwise; but trees in any case screen deformities, beautify the banks of lakes, rivers, and streams, and in a general way give fertility and colour, harmony and variety, warmth and protection, to the open country and its inhabitants, which delights the people at all seasons. The people glory in the beauty and variation of the woodland scenery, and the innumerable magnificent vistas along which they are free to gaze. We admire the woods in their many vernal shades, in their glory and splendour of complete summer array, in their autumnal tapestry, when the shades of spring green change to those gorgeous shades of decay, and in their winter desolation and nudity. In all aspects and states trees have each and all their own peculiar charm and fascination over the æsthetic mind. Yes, we love them; love them in all conditions and situations, in groups, in mass, as individuals, in all manner of combination and extent. Leaves on, leaves off, in the valley, on the swellings of the valley, in the hedgerow, along rural lanes and roadsides where their wide spreading rustic branches and leafy canopy shelter and shadow the way-worn wanderer. As spring, as summer, as autumn, as winter, she is lovely in any apparel in her arcadian dominion.

"Just think of the great plains of Britain denuded of trees and exposed to the fury of the winds, or the kingly palace or castle left standing out desolate and bare; a country dotted over with brick and stone houses without a tree near to give tone and colour to the art of the architect, or conceal the blemishes of bad art. That is a picture of the nude, not beautiful, too awful to behold. Trees expatriated to soils and altitudes other than agricultural will be something novel in British sylviculture. If this is the present day trend of sylviculture, then let us avoid such anarchy and disfigurement, and hold on to the old system; if it is not profitable, it is charmingly artistic. Alas! for the forestry of the new epoch if that is to be its consummation.

"Before pulling the old system of forestry all to pieces, which, peradventure, in the past was not the best system, nevertheless, on the whole, it fairly well realised all that was expected of it. Now let us pause. Let us have one last look behind and contemplate the grandeur and massiveness of the edifice we are about to pull to pieces, and say farewell for ever to, before we step over the brink into the future. Let us not destroy the ornate and picturesque in the old system of things (sylviculture) to gratify fantastic and crude ideas, whilst progressing towards a new system of things in camera, not even to please the most austere iconoclast. We will not reach Utopia so. Let us, when working to destroy an effete system, be sure that the system to be constructed is better than the system to be swept away. That is an important matter in the affairs of life, whether animal or vegetable. It is so much easier to be destructive than constructive. It is so easy to cut a forest down, it is so hard to grow one. It is so easy to knock all things to atoms, it is so hard to put them together again, or even to decently patch them. Let us conserve all that is good in the old system of sylviculture, while we appropriate all that is good and practical from Nature's system. Let the metamorphosis be slow, step by step as it were, so that when the transition is complete the change will not shock the æsthetic taste of the most fastidious connoisseur; and the fittest will survive, else Darwin is not a true philosopher.

"Individuals and nations sometimes pay enormous sums for oil paintings and other choice pictures. No price, indeed, is deemed too fabulous for a work of real art. Then why should people begrumble to pay a decent price for the upkeep of the great picture gallery of the world, universal Nature, teeming with the masterpieces of the master artist Nature? It were a pity if the ornamental part of sylviculture was to be consumed by the monetary."

### Plums.

Respecting Monarch referred to by "Wandering Willie," I have found it one of the finest of all late Plums, although this season produced a very scanty crop; but even then it scored over Rivers' Prolific, Denniston's, Transparent Gage, and Angelina Burdett, which were utterly bare. Emperor and Czar were the only fruited with me this year other than the first mentioned variety.—SQUIB.

### The Keeping Property of Fruit this Autumn.

I should greatly like to know what is the general experience of growers as to the keeping property of Apples, Pears, Plums, Cherries, Grapes, Figs and fruit generally, in Great Britain and Ireland? I am a small amateur grower with little more than twenty varieties of the first three, but I claim to be a pretty close observer, and my notes so far go to show that Apples and Pears specially, never kept worse, although kept cool and dry and tenderly handled in an open shed, and so far at a temperature not exceeding 55deg Fahr. I attribute the comparatively inferior flavour and bad keeping properties to the limited sunshine and ripening the fruit received.—W. J. MURPHY, Clonmel.

### Vegetable Pests.

I enclose a few stems of Savoy Cabbages which I believe are affected with the Cabbage root-eating fly, *Anthomyia brassicae*. The attack is very general this season over a wide area of the Cabbage growing district of Ormskirk (Lancashire), where every farmer grows some. Almost every grower is more or less affected. The field from which the roots were drawn is about seven acres in extent; it was Oat stubble ploughed up last autumn and winter, or rather early spring, worked in the usual way; there had not been a previous crop of the Brassica family on the field for at least a generation; the farm is a large one.

At planting out time it was given a liberal dressing of what is known as Yankee Manure, that is, manure that is taken from cattle boats plying between Liverpool and America. The supply running short, the last acre had to be planted without manure. Drills were drawn out the usual distance—28in apart—the manure spread at the bottom, then covered up, and the plants set out about 18in apart. The seed was obtained from a neighbouring farmer and was home saved, and the plants were all taken from the same seed-bed. I may here mention that it is the custom of the growers to go over the entire seed bed, drawing all the plants of an even size first, then following on with the smaller plants afterwards.

Now for results. The first three acres or so that we planted are a good healthy lot, the remaining portion of the field are very irregularly affected. There will, perhaps, be a patch of two or three drills wide for twenty yards or so on which there is only one here and there any good, followed by about half a dozen healthy plants, and so on through the remainder of these drills. Next will come a fairly good drill, perhaps only to be followed by a couple that are equally as bad, so that the last four acres of the field may be described as patchy. There is no difference perceptible in the attack on the portion that had no manure from the rest of the field, but there is a marked difference in the growth of the unaffected plants growing on two portions. When asked, I told the farmer that probably the first lot had got a start into growth with little or no check, perhaps having had the benefit of a shower when newly planted, thereby enabling them to resist the attack of the grub, as he calls it; whereas the others may have had a check from want of rain. I had that theory soon knocked on the head by the experience of another farmer whom I afterwards met; he said his plants got away splendidly after being planted for some time, then suddenly they turned a bluish colour and fell over on their sides if touched. I thought I had found an explanation of the cause in this way; this fly is very similar to the Onion fly in its habits. Now it is a well-known fact to many gardeners that if they thin out their Onions in dry, hot weather they are simply courting an attack of fly if the ground be at all strong. I thought the fly here got a foothold after the first lot of plants had been drawn, and my idea was strengthened by farmer No. 1's plants of the first "pulling" being all right; now farmer No. 2 said his first "pulling" were the worst, the latter lots not being so badly affected. Strange to say, it is the early Savoy that are

the worst, the later kind and Cabbage and some Cauliflower are not so badly affected.

I am afraid it is too late now to check the evil, the plants being too far gone; but can you suggest anything to prevent a recurrence of the attack next season?—JOHN RYLAND.

### October Chrysanthemums.

Unlike "H. D.," I have not found Market White fade to any extent after cutting. I have used the blooms for buttonholes considerably, and for the purpose I class them as very fine. Its purity, fine form, and size make it a variety that will take some beating.—T. W.

### Fruitless Forest Trees.

I observe that the Eastern and Western Planes, Oaks, Horse Chestnuts, and Spanish Chestnuts are practically without fruit this year. I have also particularly noticed that numerous of the latest partially developed leaves on several large old trees of Planes in this district were shrivelled up, apparently owing to late frosty weather; the Fir and Larch trees which are grown hereabouts are also devoid of cones this year. Probably such an unusual general absence of fruition of the above subjects in this district was owing to the inclemency of the late spring weather. Strangely, however, such as the Filbert, Cob, and other varieties of Nuts have never been known to be more abundant.—W. G., Harborne, Birmingham.

### A Seedling Carnation.

I send to you a bloom of a seedling Carnation raised by one of my men here, Holland, Sussex. It is a Tree, and I have named it Lady Betty. As you will see, the colour is very much the same as Joliffe, but the bloom is larger, more compact, and altogether a great improvement on that variety; also it is clove-scented. Kindly give me your opinion of its mercantile value.—C. H. MATHEWS.

[The flower was so withered from having been packed in dry tissue paper, in a very small box and with a short stem, that its merits could not be correctly gauged. The colour is pleasing, fragrance delightful, and size fair; it also has a good calyx, and generally seems strong. Its mercantile value will depend greatly on its floriferousness and vigour. A trade grower would be better able to inform you on this point.—ED.]

### South African Gardening.

In your issue of September 4 last, an interesting article appears on "South African Market Gardening;" and, of course, the Rand is the principal centre of attraction. No doubt there is, and will continue to be, a great demand for fresh vegetables in Johannesburg if the population continues to increase as it is doing. I shall quote a few instances of the prices given for vegetables at the market there: Three Cauliflowers, 13s. (but that was exceptional); three Cabbages, 7s. 6d.; Lettuce, 3d. each; Leeks, 4d. each; Turnips, 4d. each; Onions, 3d. each; Green Peas, 1s. per pound. This sounds well, and better too, if digested with the article mentioned beforehand. Mention is made about cheap labour, viz., natives at 15s. a month and some cheap food allowed. I should like to see the grin of the Kaffir or the independent look of the Coolie when such a wage was offered him. No, do not expect that, but be prepared to pay, at the lowest, from £3 to £4 10s. a month with rice for the Coolie, and mealies and some meat for the Kaffir. Then another important point is that the prices above stated for vegetables are procured at the worst time of the year for production. I mean winter and early spring, when, to produce these vegetables a plentiful supply of water must be under control, and, further, nearly all, if not all of the springs are already commandeered outside the Rand, principally by the Portuguese, who work from early morn to night, and at a lower wage than Englishmen would care to work for. Of course, that matter can be easily remedied by going twenty miles or so out of town; but there is a need for more railways throughout the land to convey the produce to the towns. At present much of the produce comes from Natal and Cape Colony, but fresh goods undoubtedly take the highest price. The postscript by the editor after the article gives a true account of the land, the climate, and the difficulties to be met with. To anyone having a mind to come and start market gardening at the Rand, kindly take a hint and have a good supply of money to fall back on; if you don't do so, you will find out your mistake when it is too late, as fortunes can be lost and made here in market gardening as well as at home.—S. A., Johannesburg.

#### *Helianthus rigidus.*

Taking everything into consideration, I am inclined to call it the best of the Sunflowers. Here in the garden it has been in bloom for two months at least. I do not think it is as generally known as it deserves, for we have sent out a great many plants of it in the last six years to people who saw it here for the first time.—B.

#### *Pinus Ponderosa.*

Thus, the Bull Pine, Rock Pine, or Black Hills Pine, as it is popularly known, is the best native Pine in N. America, and does well in Great Britain. It is common throughout the Rocky Mountain region and Nebraska. A form of it is also found in the Eastern States, and is now called *Pinus ponderosa* var. *scopulorum*. The type is a beautiful stately tree attaining a maximum height of about 300ft, and a trunk diameter of 15ft. With its beautiful long deep green needles and straight body, it makes one of the finest evergreens for planting on dry hillsides or uplands, and it does not seem to attract the insect now so destructive to the White Pine, *Pinus strobus*. If the tree is nursery grown and has been subjected to judicious root pruning, it is not hard to transplant and should be used a great deal more than it is.

#### Suspension of Life at Low Temperatures.

In a paper by Professor Allan Macfadyen and Mr. Sydney Rowland, read at the recent conference of the British Association, the suspension of life at low temperatures was discussed. Experiments were made with organisms possessing varying degrees of resistance, ten organisms altogether being used and cooled down to — 190deg C., in the first instance for twenty hours, and eventually for seven days. These exposures did not produce any appreciable impairment in the vitality of the organisms, either as regards their growth or their characteristic physiological properties, such as pigment and gas production, pathogenicity, &c. Amongst the organisms tested were photogenic bacteria, and these likewise preserved their normal luminous properties. The authors were able, through the kindness of Professor Dewar, to apply a still severer test, namely, an exposure to the temperature of liquid hydrogen (about — 252deg C.), a temperature which was far removed from that of liquid air as was that of liquid air from the average summer temperature. Ten hours' exposure to this temperature had no appreciable effect on the vitality of the micro-organisms tested. At such temperatures it must be assumed that the chemical metabolism of the cell ceased, in the absence of heat and moisture. At the same time, it appeared advisable to test the influence of a prolonged exposure to low temperatures on the vitality of cells. The experiments were conducted with the aid of the liquid air plant at the Jenner Institute of Preventive Medicine. The bacteria were suspended in small loops of platinum wire or on cotton-wool swabs, and directly immersed in the liquid air. The yeast, washed and pressed, was wrapped in rice-paper, and likewise directly immersed in the liquid air. Samples were taken and tested at intervals for a total period of six months. In no instance could any impairment of the vitality of the organisms be detected. Judging by the results, the experiments might have been prolonged for a much longer period than six months without appreciable influence on the vitality of the organisms in question. The ordinary manifestations of life ceased at zero, but at — 190deg C. they had every reason to suppose that intracellular metabolism must also cease, as a result of the withdrawal of two of its cardinal physical conditions, heat and moisture. It was difficult to form a conception of living matter under this new condition, which was neither life nor death, or to select a term which would accurately describe it. It was a new and hitherto unobtained state of living matter—a veritable condition of suspended animation.

#### *Sophora japonica.*

This lovely tree does not flower freely in this country. The flowers are borne in great bunches, are cream white in colour, and in seasons like last summer, when the bunches of bloom are abundant, it is one of the most attractive of midsummer flowering trees. It is a native of Japan, and belongs to the leguminous order of trees. It is slow growing at first, and one has to wait some years for a specimen to flower, but when old enough and it commences to bloom, it continues to do so every season. In favourable seasons the seeds ripen, but at all times they are easily had from dealers in Japanese seeds, and they germinate readily when fresh.

#### *Viburnum Opulus nana.*

Some years ago a pigmy *Viburnum* was introduced, a miniature form of the common *Viburnum Opulus*, and, though now fairly distributed, it has never been reported as having been observed in flower. But it has good qualities enough without this; and anyone looking for a dwarf, bushy shrub, of but a foot or so in height, would find just what they require in this plant. When raised from cuttings—and it roots easily—it takes as many as a half-dozen years before it is a foot high, but all the time, from the start to the end, it is as bushy as a plant can be. It is all the time as broad as it is high, and as thick as it can be, the branches are so numerous. For a dwarf boundary hedge it is one of the best plants going; and it is among the hardiest of plants.

#### *Kerria japonica.*

That the public does not tire of good things is evidenced in the case of the old *Kerria* or *Corchorus japonica* (writes Mr. Meehan in an American journal). In this vicinity it is one of the oldest of garden shrubs, and it is just as much in demand to-day as any of the newer shrubs. It deserves to be; for besides its wealth of yellow flowers in early spring, there is hardly a day throughout the season when a flower could not be had from it. The kind always looked for when a *Kerria* is asked for, is the double-flowered one, as it has so long been familiar in gardens: but there has appeared of late years the single-flowered sort and a variegated leaved one of the single, both free flowering and in many ways desirable. Those having plants, and wishing to increase them, could put in green wood cuttings at this season, and in winter make cuttings of the hard wood, planting or setting them outdoors when spring came.

#### *Bougainvillea Sanderiana.*

After potting *Bougainvillea Sanderiana*, plants that have been lifted from the open ground, where they have been in sub-tropical bedding, should be placed in a greenhouse lightly shaded, at a moderate growing temperature for about ten days or so, spraying them over the top daily, until they have recovered from the effects of the lifting. After this has been accomplished reduce the temperature to a sufficient degree to prevent the plants from making new growth. Clean off all shading, expose the plants to the full light, and always keep them on the dry order throughout the winter, when the plants will have well ripened and fully budded up. About six or seven weeks before Easter move the plants from their dormant position into the forcing house, give them plenty of water, and expose them to the full light. If these directions are carefully followed, there should be no trouble whatever in blooming these plants in profusion.

#### Planting Deciduous Trees.

Now that November is almost here, it is much better to proceed at once with the planting of deciduous trees than to wait longer. The leaves are still on the trees, and these have to be handstripped before the trees are shipped or planted; and quite some time is occupied in stripping even one large tree. But even if the customer should have to strip the leaves himself, he had better set out the trees. Many years' experience, writes Mr. J. Meehan, has shown that early planted trees do far better than those set late. There is root action at once if set while the ground is still warm. Should the soil be dry, so much the better for planting, as it can be worked in around every root closely. But when the hole is half filled up, drench it with water, filling up the hole later when the water has thoroughly soaked away. It is much the better way to set out trees early in the autumn than in the spring. The trees do better, and there is less need of hurry.

## Botanic Gardens.

(Continued from page 381.)

The mode of arrangement of botanic gardens varies much in detail, yet more or less faithfully reflects the state of scientific knowledge and of horticultural and general taste at the period of its foundation or reconstruction, hence we see the advantage of more modern botanic gardens. The Linnean system of arrangement of the plants has, of course, now been replaced by the natural system, but in their mode of expressing this, few gardens agree. In some, the arrangement of the plants according to their geographical distribution is followed, while economic and medical interests have had a place in others.

The grouping of plants as trees, shrubs, perennial herbs, annuals, aquatics, &c., is generally followed. The best garden may be taken as that which best combines all these advantages and reconciles them with the respective claims of simplicity and beauty, yet no garden is complete without its herbarium, library, museum, its laboratories for research, and its lecture rooms for teaching purposes. A botanic garden is concerned with the introduction of new plants and their distribution to other gardens, public or private, and to new countries, and thus requires a colonial and international organisation of exchanges and correspondence.

The advantage to horticulture by the establishment of such gardens was of the first importance. No plant can be cultivated with success unless its native climate, soil, and habitat are taken into consideration. This, and much more is considered in a botanic garden where plants are associated in cultivation. National establishments of this kind have the power both by a command of foreign intercourse and liberal funds to collect specimens of new or rare plants from other countries, especially such as have been little explored.

Here the man of science can pursue his studies under favourable circumstances otherwise unattainable, in ascertaining the relationship of individuals, comparing dubious species, witnessing their state at different periods of growth, as well as the soil and situation that suits them best. It forms a natural centre for the preparation of scientific travellers, and the training of gardeners, foresters, &c., while it owes service both to medical and general education.

The earlier botanic gardens consisted necessarily of plants grown in the open air. Indoor cultivation did not commence till about the middle of the seventeenth century. The greenhouse and hot-house in the Chelsea Physic Garden were probably the earliest erected in this country. The cultivation of herbaceous plants in the open air or with merely winter shelter in frames still remains one of the most important features of botanic garden work. Where the great aim is to get together as large and representative a collection of plants as possible, so that people may see them in a living state, features of special plants are sometimes made, such as Orchids, Ferns, Succulents, Alpines, Aquatics, or trees and shrubs, or special prominence may be given to plants used in medicine, arts, or manufactures, or such as provide food in any shape or form. Experiments and tests are often carried on and the results published in the various scientific journals. For the full performance of all these varied functions, the resources of a great botanic garden are never too ample. It is important to note that for the purpose of teaching, a much smaller one, illustrating all the chief natural orders, or the plants used in any particular industry in the neighbourhood, or the plants of the county or those that are native of

one's country, could be easily grown at trifling cost, and within very narrow limits. Several such small gardens have been established recently in the United Kingdom, as, for example, at St. Andrew's University, Yorkshire College, Leeds, and at Aberdeen.

Some of our large schools, too, possess them now, and others, I am glad to say, are in contemplation. Those already established have been followed by most beneficial results. Most universities, cities, and large towns of foreign countries have their botanical gardens.

Most botanic gardens issue annually a list of the seeds collected from the plants grown. These are available for exchange. This is very useful, not only in keeping up a general collection, but also when any particular genus or natural order is under consideration.

I will now give a brief account of the following botanical gardens:—Kew, Edinburgh, Glasnevin, Cambridge, Oxford, and the Chelsea Physic Garden.

### The Royal Gardens, Kew.

Kew is popularly known as a great botanical institution, possessed of a garden wherein is grown the most comprehensive collection of plants ever brought together in any country. Her influence in science and commerce has long been acknowledged as pre-eminent among botanical establishments. Kew is also a great training school for gardeners, but the important part she plays in horticulture has not until recently been recognised. Kew men are everywhere, as directors, curators, superintendents, head gardeners, foremen, nurserymen; and as editors and assistant editors on the horticultural press, as botanists—Fellows of the great scientific societies.

The term for employment at Kew has been limited to about two years, in order to give a large number of young men an opportunity of gaining experience there. There is a well-stocked library of books on botany, horticulture, and kindred subjects. Courses of lectures are now given on the following subjects:—Economic botany, geographical botany, descriptive and systematic botany, and physics and chemistry. There is also a British Botany Club for field

*Bambusa palmata.* (See page 409.)

work during the summer months. The director grants two half holidays, so that the members may go further afield. These outings are generally conducted by one of the

members of the herbarium staff, and are much appreciated. Prizes are given at the end of the year for the best collections.

In the long winter evenings the Mutual Improvement Society meets, when essays are read by members; or occasionally one of the officials gives a lecture, when there is sure to be a good gathering. These essays and lectures, together with the debates, are a great boon to the young men, coming, as they do, from all parts of the country. Then the daily employment in the care and cultivation of the collections furnish the practical experience so necessary to all good gardeners. Three-quarters of an hour one day in each week is allowed after breakfast, so that the young men may have an opportunity of visiting different parts of the garden to see what plants are in flower, or what work is in progress, the extent of the collections, &c. This also gives the young men a chance to see any particular department or class of plants they may be specially interested in. It must be obvious to everyone that such an arrangement is the only one possible to enable those employed to keep in touch with the working of such a large garden as Kew. There is also a cricket club, which is very popular as a recreation, good for body and mind. All these advantages, and the mingling of men from all parts of Europe, is bound to have a powerful influence in the training of the young men employed there.

Kew, as a garden of any pretensions, was founded in 1739 by Augusta, Dowager Princess of Wales, the mother of George III. Its area was then nine acres, and it was superintended by William Aiton, who had been trained by Philip Miller in the Physic Garden at Chelsea, which was the Kew of that period. Under Aiton's management and with the aid of Sir Joseph Banks, the garden increased in size and interest until about the year 1800 it was famed throughout Europe for its great collection of plants. We may therefore reckon that Kew has been a great training school for over one hundred years.

In 1840 there was a strongly expressed desire throughout the country that the garden, which at that time belonged to the Royal Family, and was but a private garden, should be placed on a different footing and rendered available as a great instructive and scientific establishment for the advantage of the public. Dr. Lindley, a great horticultural teacher as well as botanist, recommended that Kew should be made a National Botanical Garden, and maintained by the Government.

Kew is now all, and a great deal more, that Dr. Lindley recommended. Its present area is 250 acres, the greater part of which is planted with trees, shrubs, and herbaceous plants. There are about forty plant houses, including the great Palm house, and the much larger Temperate house or winter garden recently completed, and numerous propagating pits and frames, besides three large museums and a picture gallery of good paintings of plants in their native country by the late Miss M. North, and the finest herbarium of dried plants in the world. The present staff numbers about 170, of which sixty are gardeners. The collection of cultivated plants amounts to about 20,000 species, of which 6,000 are hardy herbaceous and Alpine plants (including hardy bulbous plants), about 3,000 are hardy trees and shrubs.

The first printed catalogue of the plants grown at Kew in 1768, entitled "*Hortus Kewensis*," consisted of 458 pages, and reckoned to contain 3,389 species, of which 2,712 were herbaceous and Alpine, including Ferns and bulbs, and 488 were hardy trees and shrubs. Lists of the collections now cultivated at Kew may be obtained at the gates. These catalogues are extremely valuable to all growers of plants. The Botanic Garden, which was opened to the public in 1841, with Sir William Hooker as director, comprised only eleven acres. In 1847 another forty-seven acres were added by permission of the late Queen for the formation of a Pinetum, but this was too near the London smoke, and soon lost its distinctive character, although a few of them have lingered, and are now good specimens.

The present Arboretum (also known as the Pleasure Grounds, as it was formerly used for sporting purposes by the King of Hanover) was commenced in 1870, and consists of about 3,000 species of trees and shrubs. The great object of Kew is to grow all the best and most interesting plants from all parts of the world, and to make a good display of ornamental gardening; but unlike a University botanical garden, they are not bothered with the growing of large quantities of material used in the teaching and for purposes of research in modern botany.—ALBERT HOSKING.

(To be continued.)

## Renewal of Old Fruit Trees.\*

It frequently occurs that a halo of sentiment hangs around and envelops the old fruit trees of our gardens, dating, perhaps, from the days of youth, when it was a real pleasure to pick and eat a fruit (when the gardener was away), and to feel that by that unrighteous act one had added a mite to one's horticultural knowledge; for, as a member of the family, we felt we had rights in the fruits of the orchard and gardens which were not always recognised by the reigning chief. And as we grew up and came home—possibly to take the place of beloved parents—a certain fondness for the well-known old trees appealed to our minds, and we could not entirely yield to the gardener's suggestion that "them old trees wasn't no sort of use, and had better be made into faggots," and some fresh ones be purchased to put in their place. So it came to pass that, after a quiet talk, we assented to half measures and gave the old trees another trial, either by grafting some new varieties upon them, or by cutting away the old mossy and gnarled spurry boughs, and assisting them by a liberal stimulant at the roots.

Now, it is possible in many cases thus to renew aged trees; Pears are particularly amenable to treatment; Apples partly so. But worn-out Plums, Peaches, and, in fact, all stone fruits (except Cherries in orchards) are better destroyed at once, and replaced by new trees of the best varieties, using a liberal supply of fresh turfy loam to start them in. Under such treatment they will soon respond to the trouble bestowed on them and quickly fill up the vacancies.

Stone fruits will not endure that severe pruning which is necessary to renovation, being liable to "gum" on the strong shoots produced, or to "collar" at the junction of the new growth with the old stem, and thus blow out under the strain of heavy winds, or choke with gum and become useless. Cherries in orchards, however, never get beyond treatment, and to renovate them the trees should be gone over as soon as the crop is gathered, all the dead wood removed, and the boughs which are injured by breakage, or "splits" from contact with ladders, &c., at gathering time, or from the strain of an abnormal crop, be cut away. Then, if in pasture land, the long strands of grass, thistles, and weeds should be mown, and with the cuttings and prunings removed from the orchard and burnt. Sprinkle salt at 2 cwts. to the acre over the ground, and when a new growth of grass has set in turn in some ewe sheep and feed them with oil cake, chaff, Oats, Peas, or Barley once a day; move the feeding troughs every other day to fresh positions, until the new grass is fed down as close as a Turkey carpet, and continue this treatment through the winter, giving more or less food to the sheep, according to the weather, naturally most in cold times. The droppings of the sheep will gradually improve the grass sward, and cause the Cherry rootlets to rise in March to the surface for the nourishment to be found there. An earlier crop of foliage will thus ensue, which will protect the young fruit from those severe frosts which often occur in May, and even in June. The fruit will be nourished by every shower that falls, and after it is gathered new growth will be stimulated and a store of vigour imparted to the trees for the following year's crop.

On light soils the land in Cherry orchards may be again dressed with salt or kainit, and on heavier soils a dressing of 20 bushels of soot, or 5 cwts of basic slag, to the acre in February, will be of infinite value to the trees as well as to the grass. The same system will also renew or invigorate Plum, Apple, and Pear orchards, but the boughs should be very severely thinned, the useless spurs removed, and the centre of the heads of the trees kept clear and regulated.

In renewing old Pear trees trained on walls one system is to cut out every other lateral tier 6in from the main stem and start the shoots behind the cut to form new tiers. Afterwards, the remaining worn-out tiers can be served in the same way, and thus the tree will in time be entirely renewed with young wood. In cases where the variety is only second rate (as so many of the Pear trees are that were planted some fifty years back) the lateral shoots can be grafted 1ft from the main stem, and in two years' time will begin to give a small crop. Supposing a tree of eight tiers of branches, as many different varieties of recognised merit can be grafted in, or the tree may be used for the testing of new varieties, and in this manner a crop can be relied on in three or even two years, the root vigour of these old trees being

\* Paper read on January 28 1902, by GEORGE BUNYARD, V.M.H., at the meeting of the Royal Horticultural Society.

very powerful; if needed, some stimulant mulching lightly forked in may be used to assist the new growth. Another plan which I have seen successfully carried out is to remove all the branches and main stem down to the lowest tier, and by this radical operation the formation of strong new shoots will be stimulated from this lowest tier, which can be encouraged to grow in an upright form at such regular distances as are desired.

In this way a crop is readily secured the second year; and it is a very good plan for varieties which, like Jargonelle when old, often fruit on the ends of the branches only, and for other varieties which form a mass of fruitless spurs.

As regards overgrown pyramids and bushes, both of Pears and Apples in gardens, I should advise that all of poor or doubtful quality be at once dug up and destroyed; while those which are of good recognised varieties should be allowed to grow in a free and natural way, merely thinning out the superfluous inside shoots; they will thus soon produce freely on the branches of two or three years' growth.

In cases where Pears are on the Quince, stock and Apples on the Paradise, they are more easily dealt with, as the roots

## Insects as Garden Adornments.

Amongst the moths which assist in adorning our gardens are various species, large in size and strong-winged, of which we cannot often get a good view of, not even when they are hovering above flowers. Evening is their time of flight; they prefer the dusk, and on moonlight nights seem reluctant to show themselves. Still, they are conspicuous as seen on the wing, and might be taken for bats. Sometimes their eyes shine out like little stars. Is this luminosity phosphorescent or electric, I wonder. Some make a hum when they fly, others a sort of rustling sound. There are times, though, while they happen to rest on a tree trunk or paling during the day, that afford us a good look at the upper wings at least. The big hawk moths are sluggish then; you may even give one a push and it will not budge, but strikes with the front pair of legs, as if it would say, "Leave me alone." Out for a morning walk in summer, I

A Weeping Ash at Nostell Priory. (See page 398.)

are closer to the stem; and if a trench be made round each tree, the coarse roots removed, and the trench filled with fresh soil, the new rootlets formed will be so abundant that the tree can readily be lifted and removed the following October, and be either placed in a new position, according to size and vigour, or be regulated in their former positions and refreshed with new soil to work in. We prefer, however, to make an entirely new plantation with the old trees elsewhere, and to substitute (after a year's fallow or inter-crop) a fresh lot of trees altogether to fill up the ground thus left empty. This gives a chance of renewing the old stale soil, and also of introducing new or desired varieties.

Where, however, the garden is limited, only half of the old trees should be operated on in one season in order to lessen the chance of an entire failure in the supply; but the old removed trees will after a season's growth more than reward the operator for any trouble he has taken with them.

So far as cordons on walls are concerned, we should prefer to replant entirely, remaking the borders at the same time, as new trees can be purchased in a forward state at a cheap rate, as severe measures frequently prove unsuccessful.

(To be concluded.)

spied on a fence, in repose, a fine lime-hawk moth. By a little coaxing I got him to crawl upon my hand and carried him along half a mile, then moved him to another fence.

Our largest British moth, having the formidable name of the Death's-head (*Acherontia atropos*) is an insect of singular ways, and one of its peculiarities is, that though July is the usual time for emergence, specimens sometimes appear in October or even November. There are few flowers for them then about the garden. Perhaps they visit the Ivy bloom. An eccentric one has been caught sipping from a treacle cask at a grocer's. More than the nectar of flowers does this moth love honey stored by bees, hence its visits to the old-style straw hives still existent in some gardens. Can the stings of bees penetrate its elastic covering of cuticle? We think not, yet a bee might find out some weak place in the moth's armour. Anyhow, this insect has been discovered dead in a hive. It may enter but not manage to turn round and escape, especially if gorged with honey. The notion that its peculiar cry alarmed the bees does not seem to have sufficient proof. I doubt bees being affected by this, but it has terrified superstitious humanity. The moth is handsome, its rich brown wings are curiously mottled and

banded, its thorax having the markings compared to a skull and cross-bones.

Its caterpillar is handsome, too, but in a different style. Like the moth it is averse to daylight display, and mostly feeds at night. The general colour is yellow or light brown, sprinkled with black points, and on the sides are seven bluish stripes, having a white edge, and the back bears a rough horn, which is recurved. Potato fields yield the greater number of these caterpillars, which are scarce in some years, and seldom occur plentifully enough to do serious damage, but when large they devour many leaves. The tubers of the plant are not interfered with. Specimens have been found feeding on the garden Jessamine, and more than once on the Tea-tree (*Lycium barbarum*). A few said to have come from a Privet hedge, were probably feeding upon the climbing Bittersweet or Woody Nightshade which grows along some hedges, even in London suburbs. Evidently, before the Potato arrived, the species fed on some of our native Solanums. Occasionally these caterpillars are about 4in long, and they have, like the moth, a power of producing a sound, but sometimes there are silent specimens. This sound is rather, Newman says, like the snap of an electric spark.

Approaching the Death's-head moth in size is the *Convolvulus* or unicorn hawk, less showy, for its wings are grey, but the body has brighter bands of colour. This is an erratic species, causing much speculation to entomologists; one year the moths appear all over the country, then for several years it is exceedingly scarce. This is a late species, being on the wing at the end of August and in September. It is furnished with a long spiral tongue, so poises itself high over a flower. It has often been taking sipping nectar from the *Petunia*, or the sweet scented Tobacco. Occasionally a moth has entered a house, attracted perhaps by a light, its presence sometimes alarming people. The food of the caterpillar is either a wild *Convolvulus* or a garden species. It is seldom discovered, since it carefully conceals itself during the day. Herein it differs from its relative the Privet hawk (*Sphinx Ligustri*) that caterpillar is conspicuous upon the hedges in the morning and towards evening, but it usually retires to the middle of the bushes while the sun is hot. It is well known by its violet and white stripes upon a ground colour of pale green, feeding on Privet or Lilac in August and September. Generally, the moth emerges at midsummer, or shortly after.

Most gardeners make acquaintance with one or other of the species of *Smerinthus*. I have had the Poplar hawk, *S. populi*, shown me most frequently, taken reposing upon a wall or in a conservatory. With twilight it is on the wing, like its brethren, but is not particularly rapid. Various Poplars furnish food to the caterpillar, which is rough, yellowish green, and striped. It is reported to have been taken upon the *Laurustinus*. A fine, though not a showy moth, it is surpassed by the eyed hawk (*S. ocellatus*), which has the brown upper wings tinged with red, and beautiful eye-like spots on the lower wings. This is a moth of May and June; the caterpillar feeds later on, its usual home being a Willow or Poplar, but I have taken it off Apple trees in Gravesend and East Ham. It is rather like the preceding, but paler, and distinguished by its horn, which is blue, not yellow. The lime hawk (*S. Tilia*) is remarkable for pretty shades of grey, brown, and olive green on its wings. My first introduction to the caterpillar was at Norwood, Surrey, many years ago, where a gardener, noticing that a row of Limes were somewhat thinned of leaves, went up a ladder and brought down several of these caterpillars. They have a curious shield or plate behind the horn. Frequently these caterpillars occur on the Elm, and get blown down by the autumn winds.

A lady sent me one day, with a note expressive of surprise, caterpillars of the elephant hawk, which she had taken in her vineyard. It is not a usual foe of the Grape, for this species, *Chærocampus Elpenor*, is generally taken, as caterpillar, on the Great Willow Herb, or some Bedstraw, but it has a varying appetite, and will also eat garden Fuchsias. Here the caterpillar has given name to the moth, for it is tapering, and so has been compared to an elephant's trunk. Its colour is brown or yellowish, having two black spots on each side. The moth is of good size, rather slimmer than the preceding species, of dark green with pink lines and spots, and it flies early in the summer. Then there is a small elephant moth (*C. porcellus*) which sometimes

comes to June flowers of an evening. Its caterpillar has no horn, and feeds on Bedstraws.

We must not forget the humming bird hawk (*Macroglossa stellatarum*) a remarkable species, if not brilliantly tinted. It has black and white tufts of hair along the body, which open out when it flies. "What is this," writes a poetic naturalist, "at our Jessamine with bird-like head with brilliant eye, with outspread and parti-coloured tail, humming loudly, and though driven away, returning again, day after day? It is the humming bird moth." From January to December we have some flower welcome to her, and she is most welcome to us." Certainly, it is a bold insect, but it would not bear too much driving away; nor can we expect to see it all the year round, though specimens have turned up in wintry months on a sunny day, for it is not a night species. I have seen one careering high about a drawing-room, having entered through a window in which were flowers. The caterpillar is brown or green and eats Bedstraws during the summer.—ENTOMOLOGIST.

## Seeds.

Mr. James Percival, M.A., Lecturer on Botany at the South-Eastern Agricultural College, gave an interesting and most instructive lecture at the Gravesend Municipal Technical School recently on "Seeds; their Structure, Germination, and Quality."

Taking the Broad Bean seed as a type of all seeds, he explained the structure of the Bean, drawing attention first to the mark on the edge of the seed which indicates the point where it was attached to the pod which the parent plant bore. This attachment was the means by which the seed received the necessary nourishment for its growth and support. When the seed became developed and finally ripened, the attachment dried up, and the seed remained loose in the pod. The mark, however, remained, and a similar mark was found on all seeds. Close to this point there was also a small hole, easily visible in the Bean, but not so readily seen in all seeds, though it is present even in such small seeds as *Begonias*. The object of this small hole was to admit the absorption of moisture into the seed, so as to enable the nutritive matter stored up therein to swell and become dissolved, causing growth to push. There are three great essentials in germination, all of which must be present, or seeds cannot grow. These are a suitable temperature, adequate moisture, and fresh air. Germination cannot be carried on without these. When a Bean seed germinates it may be seen to split in halves, and a small structure pushes out. This immediately commences to grow in two different ways. The radicle or root end pushes towards the soil. Should the seed be turned round away from the soil this little root end will try to find the soil again and turn downwards. Nothing can make it grow any other way. The opposite end, of course, seeks the light, and grows upwards. It cannot be made to grow in any other direction.

The two divisions of a Bean seed consist of a food supply for the young plant until it can gather for itself. They are covered with a coat or testa, which is easily removable, and simply acts as a protective covering. All seeds, though of different shape and size, are similarly constructed. Different seeds require different temperatures to germinate. None will germinate where the temperature is too high or too low. The best temperature for the germination of all seeds has to be ascertained. The majority germinate between 50deg and 80deg.

Seeds germinate the most quickly when sown immediately after becoming ripe. They then contain more moisture, and usually make a more vigorous growth than seeds that are kept longer. The longer seeds are kept, the weaker they become in germinating power. It is a fallacy to suppose that seeds obtained from mummy cases thousands of years old can grow. Few, if any, seeds can be depended upon after ten or twelve years. Stock seeds will, if sown soon after being ripe, produce a large percentage of single-flowered plants, while if the seed is kept a few years a weaker plant is produced and double flowers. The tendency is for seeds to become weaker in vegetative powers. Hence Melon seeds are preferred by gardeners to be two or three years old before sowing. Melons are required to be fruitful rather than of vigorous growth. The deterioration of the seed by age produces a weaker and a stockier growth and promotes a fruitful condition.—E. D. S.

### Rose, Golden Queen.

In an article on "Roses with Yellow Flowers," in a recent issue of "Le Moniteur d'Horticulture," a writer describes Messrs. Wm. Paul and Son's new Golden Queen, which we figured in our issue of July 11, 1901. It is stated to be "A hybrid of the Noisette section, an offspring of the variety Rêve d'Or. It is a vigorous Rose which develops a profusion of yellow flowers, of a darker shade than those of the mother parent Rêve d'Or. To ensure an abundant flowering, it is necessary during the springtime, to subdue the tall or elongated shoots, by pegging them down horizontally with the soil. The general culture otherwise, of this Noisette Rose follows that accorded to Rêve d'Or or Allister Stella Grey." We should add that Golden Queen is useful as a bedding variety, and might well be tried.

### Some New Roses of 1902.

If anything will increase the already great popularity of our national flower it is the beautiful blossoms that are still to be seen in many parts of the kingdom at this late part of the season. At a time when we are usually making preparations towards spring, we have still with us many beautiful flowers that in former years have ceased blooming before this. To my mind there is nothing more beautiful than late autumn Roses, and it is pleasing to see that most new Roses introduced now-a-days are generally noted for their wealth of bloom and late-flowering propensities. In preparing their lists for the coming planting season many readers will wish to include in their selections some new ones, so a description of a few of this year's introductions will not be out of place. Placed alphabetically we have:

**Aimée Cochet (H.T.).**—A flesh-coloured Rose, with rosy-peach centre; very large, full, well formed blooms, magnificent in bud, and a vigorous grower.

**Alice Lindsell (H.T.).**—This is a most distinct and magnificent Rose; creamy white, with pink centre. The blooms are large and perfectly formed, the petals smooth, circular, and of great substance. The growth is very robust and of branching habit, flowering with great freedom throughout the season. This N.R.S. Gold Medal Rose is certain to rank among the most select kinds for all purposes.

**Ards Pillar (H.T.).**—Too much cannot be said in praise of this lovely variety. In it we have the perfection of a pillar Rose of vigorous growth, with large, most distinct and attractive foliage; the blooms, rich velvety crimson, are produced with great freedom.

**Ben Cant (H.P.).**—Remarkably strong and sturdy in growth, with fine leathery foliage; every shoot produces blooms, and it is thoroughly perpetual. The flower, which is large, bold, and sweetly scented, is deep clear crimson in colour, with slightly darker flushes in the centre, and dark veining throughout. Awarded Gold Medal N.R.S.

**Dorothy Perkins (H.W.).**—A vigorous grower, flowering in large clusters; colour soft light pink, very fragrant and lasting.

**Edith D'Ombraïn (H.T.).**—A most distinct and superior Rose, the habit of growth being erect and very robust, with deep green foliage, every shoot bearing a flower. The blooms are large, full, and imbricated; white in colour, with an occasional pale pink tinge.

**Hélène Guillot (H.T.).**—A variety bearing large, full, Camellia-shaped flowers, varying in colour from pure white to salmon-white, tinted carmine, centre orange-yellow.

**John Ruskin (H.T.).**—This magnificent Rose is most distinct among a deservedly popular class. A vigorous grower with large, attractive foliage, bearing the entire season full splendidly formed blooms of an exceedingly rich tint of bright rosy-carmine, deliciously perfumed.

**Lady Roberts (T.).**—A lovely coloured Rose, described by the raisers as a rich, reddish apricot, the base of the petals being a metallic coppery-red, edge of petals sometimes shaded pale orange. A variety of strong growth and very free-flowering. Awarded the N.R.S. Gold Medal.

**Longworth Beauty (T.).**—A good exhibition and a good garden Rose. Colour, apricot-yellow, edge of petals distinctly margined pink. Strong healthy grower, sweetly scented, and perfectly hardy.

**Tea Rambler (P.).**—A seedling from Crimson Rambler and a Tea. Growth vigorous, producing very freely bunches of small, well-formed flowers. Colour, coppery-pink, with a salmon flush; very distinct.

Most of these belong to the Hybrid Tea class, which promises to be the class of the future. One cannot wonder at this, for they have no equal in foliage and flower, being early in bloom and lasting a long time.—J. W. J., Oswestry.

## Gadding and Gathering.

"HERE AWA', THERE AWA'."

### Shrubs at Coombe Wood.

Messrs. J. Veitch and Sons, Limited, have an extensive tree and shrub nursery at Coombe Wood, on Kingston Hill, in the county of Surrey. A visit there at this, or any other season, is time well spent, provided the weather is favourable for an inspection of the great variety of stock. It is safe to say that one has only to ask for any hardy tree or shrub, including also the "Bamboo" tribe, climbers, plants for covering buildings, hedges, the banks of streams, and choice new representatives not to be found elsewhere, and the same can be supplied. The few brief notes herewith are mainly devoted to the new shrubs which have been introduced to Coombe Wood during recent years, and there tested. It may be remembered that Mr. James H. Veitch delivered a lecture on new Japanese trees and shrubs before the Fellows of the Royal Horticultural Society on September 23. This lecture was illustrated by cut specimen branches of many new subjects, and also by photographs of the actual trees as they are at Coombe Wood. The lecture will be printed in full in the Society's Journal.

On a back page this week there is an illustration of the new *Vitis Thunbergii*, the largest leaved member of the genus, even excelling *V. Coignetiae* in this character. It is an exceedingly vigorous climber, decidedly handsome, and perfectly hardy. The autumn aspect of the foliage is indeed charming, with effective hues of scarlet and crimson. It is reputed to be a strong and free grower when well established, and speedily attains imposing dimensions. The specimens at the nursery bore out this testimony.

Another very beautiful climbing plant which is becoming known is *Polygonum Baldschuanicum*, which was found some years ago on the mountains of Turkestan, and subsequently introduced into European gardens through the Imperial Botanic Gardens at St. Petersburg. An Award of Merit was accorded to it by the R.H.S. about two years ago. The stem-growth is almost like that of the Hop, or, better still, the Honeysuckle, the leaves being larger than those of the latter, and towards midsummer, or earlier, the whole plant becomes wreathed with pendant pink floral clusters, lovely to look upon from a distance. For covering mounds made of tree roots, or for pillars, pergolas, and buildings, nothing better could be recommended. It furnished a gallant show on a pergola in the Jardin des Plantes last summer, and at Kew and Messrs. Barr's nursery at Long Ditton this climbing *Polygonum* may be seen in excellent condition.

In case these notes are curtailed to meet the editorial arrangements, I must include a notice of the beautiful North American *Rubus deliciosus*, of which a figure appears on page 400. This is one of the flowering shrubs which win regard because of their simplicity of form and purity of whiteness. The picture will convey a far better impression of this Bramble than a description could, and a position by a wall is just such as suits it. Everything that is noteworthy, of course, can be seen at Kew, and on the sandy soil there this white-flowered *Rubus* flourishes; a bed may be seen on the west side of the Ferneries. Messrs. Veitch find it a free grower and floriferous at Coombe Wood, and from them the illustration comes.

With all the freedom of a sampler of wares, one may turn sharply aside to name a Bamboo, whose merits are such as ought to ensure a place for it in every garden in the land. Groups of *Bambusa palmata* (of gardens) by the water's brink enhance the scene, and while the plant is comparatively hardy, it effectively furnishes what use allows one to describe as a sub-tropical character to the surroundings. The illustration on another page from Messrs. Veitch depicts one well grown plant. The stems are flattened at the top, reaching 5ft high. The vivid green leaves are 12in to 13in long, by 3in to 3½in broad, tapering rather suddenly to a very fine point. No other Bamboo has larger leaves. Its creeping rhizomes are very active, and the plant should therefore be grown apart from other species. This also bears the name *Arundinaria japonica*.

### The Birch Trees.

The best weeping Birches, like *Betula alba pendula* and the variety of this named *Youngi*, furnish part of the most useful material an ornamental planter has at his disposal. No tree is so graceful, so fragile to appearance (yet so hardy), nor associates better with any form of tree or surrounding features. Undoubtedly their exquisite charm of feature is heightened when they are seen depending from a bank over a smooth sheet of water, or clothing the steep slopes by the sides of mountain torrents, as in parts of the Scottish Highlands; but whether planted thus, or in colonies alone, albeit they mix well in wooded belts, their presence is unexcelled, and for decorative use they are invaluable. A number of distinctive species and varieties exist,

and though all of them are probably not in commerce, most of them are procurable.

*Betula alba* is the Silver, White, or Common Birch, and has a very large number of well-marked varieties. It is one of our native British trees, and besides being renowned for its beauty, it is also invaluable as a forest tree. *B. a. pendula* is largely used in ornamental planting, and Young's variety of it is even more graceful still, having longer branchlets and thick masses of dark, lacinated foliage. *B. alba pyramidalis* has white barked trunk and erect growing branches of a dark brown bark. The leaves are larger than those of the type and produced thickly in clusters. It is a distinctive and ornamental tree. *B. a. latifolia*, from what I have seen of it, is not robust, and makes twiggy wood.

*B. nigra*, the Black or River Birch, is rather stiff in habit, though the shoots are dependent. *B. lutea* has dark brown stems. The leaves of this species fall early. *B. lenta*, or Cherry Birch, is probably so called from the resemblance of the wood and bark to that of a Cherry tree. The leaves are 5in long and 2½in broad, and ribbed like those of an Alder. It is a vigorous grower, and furnishes a handsome tree.

*Betula ulmifolia* has greyish-white bark, but is not a very effective tree unless when a thoroughly good specimen is seen. The specific name denotes that the leaves are like those of an Elm. Undoubtedly one of the finest trees of the genus is the renowned Paper Birch—*B. papyrifera*. The foliage is of medium size, and not unlike that of *B. ulmifolia*. The habit is free and open, and the bark is silvery. Another of the large-leaved Birches is *B. Ermani*, a distinctly ornamental tree of robust character, and grows densely for a Birch. It is Japanese. The shoots are buff, or brownish. *B. occidentalis* possesses dark stems and medium-sized leaves.

The Nettle-leaved variety of the Common Birch is a beautiful tree, a native of Sweden, and quite hardy. The leaves are almost exactly like those of the Stinging Nettle, but are smaller than a typical Nettle leaf. The foliage is borne in drooping clusters, the growths being twiggy. The bark is white, and altogether this is a very beautiful tree for ornamental plantations or grounds.

In *Betula Maximowiczii* we have one of the best three Birches in cultivation. It is very handsome and distinct, and attains a height of 80ft to 90ft, with a trunk 2ft to 3ft in diameter, covered with a beautiful grey and orange bark. The dark green leaves are from 4in to 6in long, and almost as broad. The form of the tree is pyramidal, and the habit open. It is a Japanese native.

*B. populifolia* is a pretty and graceful tree, the leaves resembling those of *B. nigra*, but smaller. Lastly, there is *B. humilis*, a dwarf little bush, native of the colder parts of the northern hemisphere, and may be compared to a bushy Cotoneaster or to *Berberis Darwini*. Others that might be noted would not be so meritorious from the point of view of ornamental character.—  
WANDERING WILLIE.

### DAPHNE BLAGAYANA.

The fragrant Daphnes are always prized in the best gardens where they have once found a footing, and none are, I am certain, more thought of than *D. Blagayana*, one of the most pleasing of all, with its fine white flowers, which exhale such a delicious perfume. It lasts so long in flower that it is worth a considerable effort to secure the best results for such a charming plant for the rock garden, the flower border, or the edge of the select shrubbery. While all who have it desire this, it is also evident that all are not successful in securing such results as they strive for. This is due to ignorance of this Daphne's requirements, which are simple and are easily supplied, although they must not be neglected, or the usual result, disappointment, will follow. One must say, however, that some of the directions given for its cultivation are needlessly minute. Thus, if its other requirements are attended to, it does not mind about having full sun, although a half-shaded position may be preferable. Nor does it so much mind not having its standard compost of equal parts of peat, leaf mould, and sand, for I have known it do well in common loam, or in an even stiffer soil. Its main requirement is that its shoots, or young growths, should be bent down and kept to the soil, either by pegging or by placing stones over all but the ends of the shoots, top-dressing them at the same time, and only leaving a couple of inches or so exposed. This ought to be done in autumn, August or the beginning of September being a good time at which to perform this essential operation. It is mainly in this that success lies. No one who has seen plants so treated for a number of years and has compared them with those grown in the ordinary way will be inclined to allow their plants to be cultivated in any other fashion. This eastern European species of Daphne is one of the choicest of our dwarf shrubs, and a bed or mass of it from 4ft to 5ft across is a most pleasing object when grown on the system recommended. In a few years a plant so treated will cover this space.—S. ARNOTT.

### THE EARLSWOOD COLLECTION.

If half a dozen of the Chrysanthemum experts of Great Britain were to be named, Mr. William Wells, chief of Wells and Co., Limited, Earlswood, Surrey, would be included, and his name would still be to the fore if only three were chosen. This is his semi-jubilee year as a commercial Chrysanthemum cultivator. His introduction to the flower of his choice was singular in the light of present achievements. Mr. Wells was a private gardener prior to 1877 at Fen Place, Sussex. His employer had also a garden at Clapham Common, and it was the success of the gardener at this town residence as a Chrysanthemum grower that first fired our friend Mr. Wells to surpass the efforts of his prize-winning rival. From Clapham he secured some cuttings and gave them his attention. He was scarcely up-sides with Smith, the Clapham gardener, the first year, but by the end of the succeeding autumn, some of the blooms from the Sussex plants were so large and handsome that Mr. Oxley, the employer, and who greatly loved Chrysanthemums, remarked, "Why, William, your flowers beat Smith's." Shortly after that period, Mr. Wells commenced for himself as a specialist at Earlswood, where he has since been, and has successfully worked up a large and ever-increasing business. His motto is: "One customer well served is equal to ten advertisements."

### MR. WELLS' SEMI-JUBILEE.

About twenty-five years ago Chrysanthemums could scarcely be obtained at Christmas, and Mr. Wells' earliest assistance after starting in business for himself was derived from the sale, at 3s. per dozen blooms, of the white Miss Marcheau and the better known Elaine, both of which he was fortunate enough to have a fair supply of for the Christmas season. Cuttings of these he advertised through the medium of the *Journal of Horticulture*, and sold many. Calvat's novelties he acquired and also distributed, and step by step the fame of the Chrysanthemum advanced, and this trade grower with it.

Some years ago he and Mr. T. W. Pockett, curator of the Melbourne Botanic Garden, in Victoria, agreed to work in harmony; the latter as a raiser of new varieties in the dry, airy climate of the Island Continent, and Mr. Wells to be the distributor in England. Few of the many cuttings sent from Australia to Surrey fail.

### THE CHOICEST FLOWERS.

And now, touching the Earlswood flowers this year, I will name some of the gems of the collection. Mrs. T. W. Pockett stands in the forefront; Mrs. Alexander McKinley was irreproachable; Donald McLeod was a perfect model of a beautiful flower; Madame Herrewage was excellent, spotless in whiteness, though a trifle loose; W. R. Church, of enormous size, substance, and grand finish; Chas. Longley, undoubtedly one of the finest blooms of the day; Lord Ludlow, a fit match for Donald McLeod; Sensation, beyond words in the richness of its golden blaze and russet shading; T. Humphries, a bright and lovely flower; Lord Alverstone, a noble bloom of great size, strength, and richness of colour; and charming snowy masses in floral form representing that queen of whites, Miss Alice Byron. These eleven I have named from memory, because they so well and favourably impressed themselves at my visit on the 23rd inst.

### S. T. WRIGHT (NEW).

One I have not included, and for the reason that it ought to be named apart. It is a novelty, and bears the patronymic of the superintendent of the Royal Horticultural Society's Gardens at Chiswick—S. T. Wright. This is the Wellsian "big-gun" of the year, and no doubt hundreds of Journal readers will have an opportunity of viewing it this year. It is a massive Japanese, having stout broad petals coloured on the upper surface a rich claret-crimson shade,

with golden bronze reverse. I think the best guarantee of the worth of the new S. T. Wright lies in the fact of so notable a name having been given; and Mr. Wright may well be proud of this flower named in his honour. It is a seedling of Mr. Pockett's; it does well on first crown buds, but better on second crowns. The height is 6ft., stems and leaves vigorous, and all the buds are good.

#### CHELTONI—A YELLOW NELLIE POCKETT.

Another newcomer which Mr. Wells is immensely delighted with is Cheltoni, the entire stock having been secured by him from various parts of the country. It is a yellow sport from the delightful white-flowered Nellie Pockett, and as such it is sure to be readily welcomed. Mr. Wells has a large stock of it, part of which he received from a Mr. Lustv. of Cheltenham, who secured a certificate for it at Cheltenham. Another part of the stock was from Huddersfield, and yet another portion from Whitchurch in Shropshire. The colour is very much like that of Phœbus.

Mrs. T. W. Pockett is very liberally cultivated both in pots under glass and planted out in the open, being protected overhead by an awning. In all cases it does grandly. It is a real amateur's flower; that means it is an easy doer.

Lord Ludlow, already referred to, produces huge flowers in pots 7in and 8in in diameter. It has come grandly on first crown buds this year. O. V. Douglas furnishes an immense head of the "butter and eggs" colour mixture, and is a worthy variety.

#### FRAGRANT CHRYSANTHEMUMS.

Sweet Violet is a new purple. Few Chrysanthemums are really fragrant, but Prown may be named, also Albini, and Mrs. E. W. Clark, each being late purples, curiously enough. This makes four scented Chrysanthemums.

I can scarcely fail to mention the handsome bronzy-gold Harrison Dick, seeing that it bears my own name. This will be another of the chief of the Wellsian novelties for 1903. It is in very many respects like Matthew Smith, but more intensely coloured, and is a good doer. The stock is very limited.

Mrs. Harry Emmerton is a large yellow Jap., and easy to do, like so many others of the Australian yellows. Marica takes after Mrs. White Popham type; Madame Waldeck-Rosseau (Calvat's) is crimson-amaranth, with bronze reverse; good. Bluebeard, new last year, is so called because of the blue apparent in it along with the purple maroon.

#### OTHER NOVELTIES.

Lord Alverstone is a very handsome flower, with broad, deep crimson coloured florets, and of a dwarf habit of growth. Donald McLeod does well when treated the same as Mrs. Weeks, striking in February and taking the first bud that comes. Edith Salter, a new Japanese of merit, having lengthy petals of a soft purplish-lilac shade. Ben Wells, named after Mr. Wells' grandson, is a giant among its fellows, and is largely grown. The buds are opening well. All Mr. Godfrey's novelties are A1 at Earlswood, being firm, rich, and large.

Mr. F. S. Vallis is a monster for size, and of a pale yellow shade. It was regarded by Mr. Calvat, the raiser, as one of his best. Ethel Fitzroy, too, proves to be in the forefront, and is one of Mr. Weekes' finest Japanese incurveds. Madame L. Cheveant (Calvat) is one of those pleasing flowers which bear a second glance. It is reflexed, with moderately broad petals, silvery tipped, rosy-lilac or Peach-blossom tint, with a dash of mauve. It is exceedingly sweet.

There are many others one might describe or refer to, did space allow of it. Violet Lady Beaumont is one; Hon. Mrs. Tennant is another, also Lord Salisbury, R. Hooper Pearson, C. J. Salter, Calvat's Sun, Duchess of Sutherland, La Fuson, and Claremont, all of which are showing up well. The past season has been favourable for those Chrysanthemums which usually carry heavy and close-built flowers; they have, and are, opening nicely.—VIATOR.

#### Longford Castle.

The many friends of that very excellent man and able gardener, Mr. Hazleton, who has worked so hard to make Longford a credit to himself and its owner, will regret to hear of his leaving there shortly. We trust that our friend may soon be comfortably reinstated in a garden worthy of his merits and care.

## Societies.

### R.H.S., Scientific Committee, Oct. 21st.

Present: Dr. M. T. Masters (in the chair); Messrs. Massee, Saunders, Bowles, Worsley, Holmes, Druery, Hooper, Douglas, Gordon, Shea, and Paul, Drs. Cooke and Rendle, Revs. W. Wilks and G. Henslow, Hon. Sec.

*Roses*.—Mr. Wilks exhibited specimens he had received from the Herbarium of M. L. de Vilmorin of *Rosa sericea*, with long decurrent thorns; of *R. aculeata*, with very large thorns; and illustrations and photos of *R. macrophylla*, a large crimson-flowered species.

*Begonia, crested*.—Sir Trevor Lawrence sent several flowers showing different degrees of creasing of the petals. In some the entire petal was reduced to a midrib covered with projections.

*Leaf-miner*.—Mr. Holmes showed specimens of a Leaf-miner on Hogweed, which Mr. Saunders undertook to examine; also a specimen of *Parnassia* attacked by fungus.

*Cankerous growth*.—Mr. Hooper showed some fruit tree branches with a cankerous growth, and Daffodil bulbs attacked by the dipterous fly, *Merodon*.

*Auricula aphid*.—Mr. Douglas brought plants of *Auricula*, the roots of which were infested with an aphid, but the plants themselves were perfectly healthy. They appeared to be *Frama Auriculæ*, and had been observed twenty-five years ago.

*Vigour in hybrids*.—Mr. Douglas called attention to a plant of a hybrid between *Cattleya Doweana* and *C. velutina*; the first parent has usually three to five flowers, and the latter three only; but the hybrid bore nine. The specimen illustrated the usual result of increased vigour in hybrid plants, sometimes at the expense of fertility. It was observed that *Fairreanum* hybrids will not cross. Mr. Paul remarked that extraordinary growth occurred in hybrid *Crimson Rambler* Roses, long shoots 16ft in length occurring in one season, but accompanied with some decrease in the production of flowers.

*Carnation leaves rooting*.—Mr. Douglas brought leaves of a tree *Carnation*, one branch of which bore leaves with minute roots, arising from the pericardial region of the fibro-vascular bundles, and issuing from beneath the epidermis all along the midrib. Mr. Massee observed that it was not infrequent when eelworms were at the roots, the roots then often appear from the stem as well as the leaves.

*Exhibition of fungi*.—He also suggested that it would be advisable to hold an exhibition of fungi, displaying the edible and poisonous species in separate collections, to be collected by the members of the committee or other persons interested in them. Mr. Wilks proposed October 13, 1903, for the first exhibition.

*Cactus blistered*.—Mr. Shea showed seedling plants with blistered patches. Mr. Wortley observed that he was familiar with the occurrence for many years on old plants, but this appeared to be the first instance on young plants. He had noticed flies on it, and thought that possibly they might have been the initial cause of the mischief, the fungus following.

*Peach mildewed*.—Mr. E. Salmon sent a history of a Peach raised from a stone, first in a pot, then in an unsuitable environment, and finally in his garden, nine years ago. It bore the Peaches, which, being rather damp, were placed by the fire. "They have gone back ever since, and the skin will not peel." The one sent was attacked by the ordinary Peach mould.

*Lime trees and undergrowth*.—Dr. Voelcker inquired if there was any truth in the belief that nothing will grow under Lime trees. It was not generally accepted by the committee; but a Swede (a gardener) said that it was the common belief in Sweden that such was the case.

*Pine-bark and Coccus*.—Mr. Saunders reports as follows on specimen sent to the last meeting: "As far as I could see it was a different species to that which infests Beeches; but as I was not quite sure I sent specimens to Mr. Newstead, who replies as follows: 'I think the insect you sent to me on Fir bark is the Pine aphid (*Chermes pini*), but I could not, unfortunately, extract an insect from the white sacs. Could you send me a further and plentiful supply in order that I may make quite sure of the insect.' It is pretty certain that Mr. Newstead thinks it is a different species to that on the Beech, for he suggests that it is a *Chermes*, whereas the other species is a *Pseudococcus*."

*Ipomœa rubro-cœrulea*.—Mr. Worsley showed a blossom of this plant, observing that it has been described as being at first red, then blue, but in his experience this order was reversed, as it opens a deep blue and then becomes of a crimson tint.

*Arctotis sp.*—He also showed specimens of *A. arborescens* (white), Jacq. and *A. Leichlini* (yellow). The first named species was the first to be introduced from South Africa. The latter is called the South African Daisy, as it has white ray florets touched outside with crimson.

*Embryo buds on Tulip Tree*.—Dr. Masters showed examples of these, which are common on Beeches, Cedars, and Deodars, but not seen before on Tulip Trees.

*Gladiolus*.—Mr. Jenkins, Hampton Hill, sent a very long spike of a crimson variety. The height was 3ft 8in. It was the result of a corm which had been neglected from October, 1900, to June, 1902, when it was planted.

*Passiflora n. sp.*.—Dr. Masters showed a specimen which had been accidentally introduced with a *Cattleya Mossiae*. It had not yet been described or named.

*Horticultural Society of Picardy.*—Dr. Masters then gave a brief account of his visit to the gardens and building of this society at Amiens. A complete description will be found in the "Gardeners' Chronicle" of September 11, 1902, page 267.

*Burst, n. sp., introduced.*—Mr. Massee described the introduction into England of a new species of this fungus as follows: "Twelve years ago one of the cereal burst fungi was sent from Patagonia and Bahia Blanca, where it was stated to be very abundant. The host plants were *Bromus unioloides*, H.B.K., and *Festuca bromoides*, L. As usual, the fungus formed a black mass in the ovary of the host plant, and proved to be a new species—*Cintractia Patagonica*, Cke. and Mass. Quite recently a traveller in these regions observed that *Bromus unioloides* was extensively grown, mixed with Lucerne for fodder.

"Seed of the *Bromus* was brought home and sown in Lincolnshire, and on producing fruit was observed to be attacked by the *Cintractia*. The above illustrates one of the methods by which injurious fungi are introduced from one country to another, and unless great care be taken to stamp out the newcomer, it is just possible that we may eventually have to add another cereal fungus pest to our already large list."

### National Chrysanthemum.

A goodly number of novelties were staged at the meeting of the Floral Committee of the above society at the Royal Aquarium, on the 27th inst. The season being a late one, it is yet early for novelties to be seen in their fully developed form, and of those staged on this occasion a longer time on the plants would have added to their qualities. It is anticipated that on the occasion of the meeting of the Floral Committee on November 10 a considerable number of new varieties will put in appearance; it is, therefore, needful that the Floral Committee set up a high standard in granting certificates to novelties. Something more is now needed as an ideal than a flower which commanded a First Class Certificate of Merit two and three years ago. There is just the danger that the commercial value of an award of this character may dominate the minds of some members of the committee and lead to the honouring of varieties of uncertain value.

First Class Certificates of Merit were awarded to

*Japanese Miss Mildred Ware.*—A flower of the Madame Carnot build, said to be a seedling from a cross between *Pride of Madford* and *Madame Carnot*, in colour pinkish salmon; a kind of deep coloured *Charles Davis*, and it might be said to be intermediate in colour between *Charles Davis* and *Lady Hanham*. From Mr. T. Bullimore, The Gardens, Canons Park, Edgware.

*Japanese Miss Olive Miller.*—Silvery pink reverse, which incurving and curling towards the centre nearly hides the pale purplish surface to the long and fairly broad florets; full, deep, and very pleasing in colour. From Mr. G. Mileham, The Gardens, Emlyn House, Leatherhead, Surrey.

*Japanese George Penford.*—A glorified Edwin Molyneux type; rich crimson with an old-gold reverse; a type of flower greatly needed on exhibition stands; should this variety maintain its character, it will be a real acquisition to the exhibition stand. From Mr. Charles Penford, The Gardens, Leigh Park, Havant, Hants.

*Japanese Florence Penford.*—Yellow, with a delicate amber reverse to the broad, long, curling florets; a pleasing variety of excellent character. From Mr. C. Penford.

*Incurved Cecil Cutts.*—A large, full, bright yellow incurved raised by Mr. H. Weeks, Thrumpton Hall Gardens, Derby. Deep in colour, good petal and form, and said by Mr. William Higgs, who is growing it this season, to be quite distinct. From Mr. Thomas Mudd, Thorneywood, Nottingham.

*Rycroft Beauty.*—A very free blooming early variety of a pleasing shade of pinkish rose. Commended as a market variety. From Mr. H. J. Jones, Rycroft Nursery, Lewisham.

*Gladys Gray.*—A soft yellow sport from the bronzy *Edouard Lefort*, bearing this name. Promises to make a very useful variety for cutting from. A vote of thanks was awarded to the sender, Mr. William Gray, florist, Thorngunbold, Hull.

Mr. W. J. Godfrey, nurseryman, Exmouth, sent a collection of seven novelties, though not one was successful in gaining an award. Among them was the brilliant Exmouth Rival; F. S. Vallis, a large full yellow Jap., considered to be too much like G. J. Warren, but certainly earlier; Mrs. H. Emmerton, an Australian variety, clear yellow, but darker in the centre; Wilfred H. Godfrey, bright crimson, with gold reverse; Duke of Devonshire, yellow, with faint lines of crimson on its long drooping petals; Grandeur, bright chestnut crimson with amber reverse; and The Lion, a mild looking variety which belies its name.

Mr. W. Seward, The Firs, Hanwell, sent incurved Madge Craig, pinkish salmon base, with yellow centre, a promising flower.

Mr. H. Perkins, The Gardens, Greenlands, Henley-on-Thames, had Japanese Miss Smith, a large white in the way of Mutual

Friend; and Henry Perkins, deep orange crimson, with yellow reverse; two varieties which will, no doubt, be yet seen in better condition.

Mr. G. Shawyer, Cranford, Hounslow, had a plant and some excellent flowers of his market variety Queen of Yellows, but it did not find favour with the committee.

### Croydon Chrysanthemum, October 28 and 29.

The show of this society on Tuesday and Wednesday last was an exceedingly good one. The competition for the society's Champion Challenge Cup and also for the King Edward VII. Coronation prize was keen, and some splendid flowers came from Mr. G. J. Hunt, Mr. Bible, and Mr. Salter. Where incurved blooms were shown, these were on the whole good. A pleasing feature of the Croydon Show was the presence, in very good form too, of many of the latest novelties. Amongst non-competitive exhibits were odorous Violets from Messrs. I. House and Son; Apples, Asters, and other flowers from Cheal and Sons; Alpines from Mr. J. R. Box; decorations from Mr. Butcher; and samples of their fertilisers from the Ichthemic Guano Co., Ipswich. Our notes of the fruit and vegetable competitions are secondary to the Chrysanthemum report, but both these sections were well sustained, and good produce was seen. To the secretary (Mr. W. B. Beckett) and the committee all encouragement is due for their able management of affairs.

The first prize set in class 1 fell to Mr. G. T. Hunt, gardener to Pantia Ralli, Esq., Ashted Park, Epsom, with magnificent blooms in both incurveds and Japanese. Godfrey's *Pride* was exceedingly good, as was Mafeking Hero, Mrs. Greenfield, Marquis de Venosta, Sensation, and Mrs. J. J. Thorneycroft; while the best of the incurved flowers were Hanwell Glory, Lady Isobel, Globe d'Or, Yvonne Desblanc, Golden Empress, Ada Owen, and Violet Tomlin. The second place was awarded to Mr. F. Bible, gardener to H.S.H. Prince Hatzfeldt, Chippenham, with the premier Jap. and also incurved blooms. The premier Jap. was a splendid flower of Miss E. Fulton, which was certificated at the last Drill Hall meeting. His other choice blooms were Mrs. Coombes, with a lovely green centre adding attractiveness to it; Chas. Longley, very rich; Triumph, grand form and colour; Mrs. Greenfield, small but meritorious; Mrs. T. W. Pockett, Australia, &c. The premier incurved was a typical flower of Ernest Cannell, large and finely formed. Other good varieties were Globe d'Or, Ada Owen, Lady Isobel, and Duchess of Fife. Third place fell to Mr. C. J. Salter, gardener to Mrs. Haywood, Woodhatch, Reigate, with a collection which were of high merit. Mons. Chenon de Leclé was well shown; Miss E. Fulton was large and pure; *Pride of Stokell*, rich; Ernest Bettsworth, better coloured than we have ever seen it, a splendid purple flower; W. R. Church, one of the largest and handsomest; Lord Ludlow, fair; Mrs. T. W. Pockett, good; and others but little inferior. The incurveds were smaller than those in either Bible's or Hunt's stands.

The King Edward VII. Coronation prize for ten Chrysanthemums with their own foliage, in two vases, five Japs. in one vase and five incurveds in the other (first, Silver Cup and £3; second, Gold Medal; third, Silver Medal), was won by Mr. G. J. Hunt, as already mentioned. His flowers would have done credit to him even against the best Aquarium samples. Princess Alice de Monaco, Mafeking Hero, Mrs. G. Mileham, and Mrs. J. J. Thorneycroft were shown. The second we could not discover; and Mr. C. J. Lane third.

In class 19 (single handed gardeners) the leading position for ten Japanese blooms fell to Mr. A. Dyer, gardener to C. Peacock, Esq., of Bromley Hill; second, Mr. G. Lemon; and third, Mr. A. Martin, Stroud Green Road, Croydon. Mr. Lemon led in class 21 for a dozen Japs. in nine varieties. For Pompons in class 32, the only exhibitor was Mr. W. Philpot, 57, Church Road, Croydon, with Prince of Orange, Adele Pizette, Black Douglas, La Purité, and Mme. E. Derdea.

For a group of Chrysanthemums in pots two entrants contested. Mr. W. C. Collins, Park Hill Road, was a very creditable leader; no second; and third with poor blooms, Mr. C. Walton of Whyteleafe.

In class 7 for a dozen incurved flowers, Mr. C. Lane of Caterham led with a good set, and second, Mr. C. Payne of Batchworth, whose blooms were much smaller.

In class 9 for six blooms of one variety there were half a dozen entries. Mr. C. Lane, gardener to E. H. Coles, Esq., Caterham, was foremost with Baron Hirsch, finely formed blooms; second, Mr. G. Prebble, gardener to Miss Thrall, Shirley, with the same variety; and third, Mr. C. Payne, with Globe d'Or. Mr. G. Lemon, gardener to Miss Foster, Thornton Heath, had the only exhibit of twelve incurveds in class 23, and they were very fair.

Mr. E. Mills, gardener to F. Lloyd, Esq., Coombits, Croydon, led for the six Japs of one variety with splendid samples of Mrs. Geo. Mileham. Second out of three came Mr. C. Lane with typical blooms of W. R. Church; and lastly Mr. G. Lemon, The Grange, Thornton Heath, with Silver Queen, a pink variety.

For eighteen Japs in twelve distinct varieties there was good

competition, five handsome sets being staged. With massive and well set up blooms Mr. A. Smith, gardener to the Lady Superior, The Convent, Roehampton, was a highly creditable first. His Mrs. Greenfield was simply perfect; Mrs. G. W. Palmer was rich; Miss E. Douglas also intense; Lord Ludlow also unapproachable; and Florence Molyneux a model. This was indeed a splendid collection. Mr. C. Lane was a very good second, and had nicely finished blooms of W. R. Church, Lord Ludlow, and Kimberley. Mr. C. Payne was third.

The foremost for ten Japs in one or more varieties in two vases (class 6) was Mr. C. Payne, with General Buller and Mrs. W. Popham. Mr. Bible formed a close second with Mrs. Cocinbes, which he seems to have managed to perfection, and others; while third place was taken by Mr. C. Collins.

Class 28 made a very fine display, there being a number of handsome vases of flowers. Mr. J. G. Mills, Croydon Road, Anerley, led off; second, Mr. J. J. Pittman, Dingwall Road; and third, Mr. A. G. Burgess, Cromwell Road.

Apples and Pears, as we have noted, were well shown, the chief prizewinners being Messrs. A. Smith, Roehampton; W. Jones, and J. Simmons, Oxted, who were so placed in class 10. Mr. Lintott led in class 11, and other leaders in this section were Messrs. E. Snelling and J. R. Filce, both of Croydon; O. Jeal of Waddon; G. Woolgar of Purley; W. Jones, Wallington Bridge; C. Stew, Addiscombe Road; and C. Perrett, Duppas Hill.

In class 4 for white Grapes Mr. Lintott of Marden Parker beat Mr. W. Taylor of Forest Hill; and third, Mr. T. Smith. For black the order was first, Mr. W. Taylor; second, Mr. J. Friend, Godstone; and third, Mr. J. R. Ball of South Norwood Hill. Mr. J. Friend had a magnificent collection of vegetables in class 17, for which he was accorded the premier prize.

### Shirley (Southampton) Gardeners'.

At a meeting of the Shirley Gardeners' Association lately held at the Parish Room, Mr. J. Hudson, V.M.H., of Gunnersbury Park Gardens, gave a very interesting lecture on the cultivation of Figs. In dealing with his subject, he said it was difficult to fix the date of the introduction of the Fig into Great Britain, but it could be traced back 350 years. It had not made such progress here as the Grape Vine, for it had suffered in its reputation on the ground of non-fertility, which was rather due to the fact that it was a gross feeder. Attention should be given to the roots. They ought not to be allowed to intermingle with each other. They should, when planted out, be grown on raised borders, the same as they are in Italy, and the borders should be well drained. With regard to pot culture, it was attended with excellent results, as such plants are very fertile. They did not want repotting every year; once in three years is ample. When not repotted they should have a top-dressing in the autumn, and a dressing in the summer when the fruit is forming was very useful. A good calcareous loam mixed with stable manure was the best soil, either for pots, tubs, or borders. Root-pruning should be done as soon as the leaves have fallen. For early forcing pot culture is best. The pots should be plunged in leaves. Mr. Hudson then gave other technical details of cultivation. First how to have the crop ripe by the 1st of March; and propagation by eyes and cutting was fully explained, Mr. Hudson being in favour of the latter system. After successfully tracing the growth of the Fig from the cutting to the tree, carrying a crop of ripe fruit, he gave a few hints on disease and insect pests, and a list of the best varieties for English culture, classifying them as early forcing, general, and late crops; also the best sorts to plant outside. A good discussion followed, in which Messrs. Jones, Wilcox, Miles, Payne, and Verdon took part. Certificates of merit were awarded to Mr. Verdon (of W. H. Rogers and Son, Red Lodge Nurseries) for a grand collection of Roses and Apples; Mr. Cozen, Cactus Dahlias; Mr. Tomsett, six Peaches; Mr. B. Ladhams, V.H.C., for a collection of cut flowers; and a special vote of thanks to Mr. Wright for a very fine *Salvia* (Scarlet Queen). A vote of thanks to Mr. Hudson for his excellent lecture, and to the exhibitors and Mr. Ladhams for presiding, closed a very pleasant evening. The next meeting will be held on November 17, when prizes are offered for Chrysanthemums, the prizewinners to give their method of cultivating.—J. M.

### Beckenham Horticultural.

On Friday, October 24, a lecture on the "Growth and Cultivation of Mistletoe" was given by W. Groves, Esq., Grove House, Shortlands, G. N. Hooper, Esq., presiding. When it is stated that the Mistletoe is one of the show things of the lecturer's garden, and that he has made a special study of this parasite over a number of years, it may be inferred that his discourse would be extremely interesting, which proved to be the case. It was at one time thought that the seed of Mistletoe must pass through the intestines of birds before it would germinate. The lecturer proved the fallacy of this; in fact an instance was given when, having some plants enclosed for saving seed, a thrush got in the enclosure and consumed a great portion of the berries, but no

undigested seed was discovered in the excrement of the bird. In cultivation the lecturer has only practical experience of it on the Apple tree. The first step towards success is to procure good ripe seed; failures occur through using immature seed. A piece of net must be placed over a plant in such a way as to prevent birds getting the berries. April is the best month to sow. All that is necessary is to take the berries and squeeze them on to the angle of the young wood of the Apple tree. No cutting of

*Vitis Thumbergi.*

the bark is required, pin a small piece of muslin over the seed to protect from birds and sowing is completed.

A most interesting set of young plants of Mistletoe was brought by the lecturer, showing it in all stages from the seedling scarcely discernible up to that of six years old. An interesting discussion ensued at the close, after which both lecturer and chairman were the recipients of hearty votes of thanks for their kindness. Mr. Webster placed on the table sprays of St. Joseph Strawberry carrying ripe fruit of good size, also the same of Raspberries.—T. C.

## Highgate Chrysanthemum, October 29, 30, and 31.

The eighteenth annual exhibition of the Highgate and District Chrysanthemum Society was held for the first time in the Alexandra Palace, Muswell Hill, London, on the above dates. The show was an excellent one in all quarters, and there being ample space for the many tables, an imposing display was provided. The blooms in the leading vase class, and in class 4, were of high merit. Competition was fairly keen all through, and a number of non-competitive groups were forward. Messrs. Wells and Co., Limited, had choice new Chrysanthemums; Messrs. B. S. Williams and Son, of Upper Holloway, had table plants, Cyclamens, Ericas, *Spiræa palmata*, Ferns, and Orchids. Messrs. Cutbush and Son, Highgate, N., contributed *Begonia Gloire de Lorraine*, Lily of the Valley, and *Liliums* retarded; *Erica gracilis*, white Tree Carnation Mrs. J. S. Brookes, and purple-leaved Vines.

Bottled fruits were sent by Messrs. Austin and Co., of Kingston-on-Thames; Messrs. Wood and Son had their Velthea, also syringes, stakes, canes, Orchid peat, raffia, and many other sundries. The Ichthemie Guano Co. sent their fertilisers: Pearce and Co., Holloway Road, had model greenhouses and frames; H. Williams and Son, Fortis Green, Finchley, staged well-grown Chinese *Primulas* in flower; while Mr. J. Russell, of Richmond, had a collection of Apples.

Miss A. M. Bevan, The Lodge, East End Road, East Finchley, N., very tastefully arranged a dinner table with fruit, flowers, china, cutlery, &c.; there being *Crotons* and *Cocos Weddelliana* on the table, with good Japanese, incurved, and Pompon flowers, and excellent Grapes, Melons, Pears, Apples, and Nuts. A painting of Mr. Godfrey's variety, The Masterpiece, was also staged on a side table.

The show arrangements were admirably managed by the hard-working secretary, Mr. W. E. Boyce, and committee. The Earl of Mansfield, president, opened the exhibition at three o'clock. Numerous special prizes were offered by trade firms and by private individuals.

Mr. Witty, Highgate Cemetery, won the tempting prize in class 1, of 10 guineas and a Silver-gilt Medal, for a floral display of Chrysanthemums, any varieties, but must include Japanese, incurved, reflexed, and Pompons. Mr. G. Saunders was second. The two groups were disappointing.

The large vase class (No. 2) was one of the great features of the exhibition, and some really magnificent flowers were here shown. For twelve vases with distinct varieties Mr. J. Brookes, gardener to W. J. Newman, Esq., Totteridge Park, Totteridge, was an excellent leader with massive and highly coloured blooms of the following: M. L. Remy, G. W. Palmer, Mrs. J. Bryant, Miss E. Fulton, Mrs. G. Mileham, Mrs. T. W. Pockett, Millicent Richardson, J. R. Upton, Mrs. Barkley, W. R. Church, Australie, and A. H. Barratt. The best were Miss E. Fulton, Mrs. G. Mileham, and Australie. Second in this class came Mr. G. J. Hunt, from Ashted Park, Epsom, Surrey, whose blooms were rich in colour and very good. His *Pride of Madford* was excellent; Mrs. J. Bryant very fair; Edith Tabor good; and Ernest Bettsworth also very fine. Third came Mr. J. Kirkwood, Grass Park House, Finchley, with smaller blooms, his best being Master C. Seymour, Mrs. Coombes, Alice Byron, Mrs. Greenfield, and Mrs. G. Mileham.

Two competitors were forward for six vases of incurved blooms distinct, the leader being Mr. G. J. Hunt with flowers of good colour, purity, and fair size. He staged *Lady Isobel*, John Lambert, Hanwell Glory, and Ada Owen in splendid condition. A good second set came from Mr. A. Jones, Hadley Manor, Barnet, with fine samples of Mrs. N. Molyneux, Gen. Symonds, and Louisa Giles. Three entered.

For Messrs. Wells and Co.'s prizes in class 4, Mr. J. Brooks, of Totteridge Park, led off with a creditable dozen blooms. Mrs. Pockett, W. R. Church, Mrs. G. Mileham, Calvat's Sun, and Chas. Longley were the best; but all of the set were good. Mr. G. J. Hunt was considerably behind, but had a good Mrs. Mileham. No third.

Mr. T. L. Turk, gardener to T. Boney, Esq., Southwood House, Highgate, led in class 5 for a group of Chrysanthemums, and included some very pretty Pompons. Second in the same class fell to Mr. G. Saunders, 13, Victoria Cottages, Archway Road, Highgate, but the plants were rather tall. In class 6,

the first fell to Mr. C. J. Webber, 6, Colney Hatch Lane, Muswell Hill; and second, Mr. J. Adams, gardener at Hillside, Fitzroy Road, N., both with fresh-like groups.

The table decorations furnished quite a leading feature. In class 8 for a decorated table, Mr. D. B. Crane was adjudicated first position with a rich display; Mrs. Wheaton, of Tenterdown, Muswell Hill, formed a capital second; and third out of six, came Miss Saunders, with a fourth to Mr. D. M. Oliver. For a similar entry, class 10, Mr. D. B. Crane was again leader; Mr. Oliver and Mr. G. Shrimpton following so.

For six vases of Japanese blooms, class 9, Mr. T. L. Turk well deserved the leading place; Mr. J. Stonebridge, Bishopwood, was second, but no third competitor entered. Mr. Brookes led off in class 42 for a dozen Japs. arranged with foliage and grasses; and second, Mr. J. Stevens, of Thirsk Lodge, Stanhope Road, N.

Mr. J. Brookes was foremost for a vase of six Japs.; Mr. G. Frost, East Hill, Oakley Park, second; and Mr. J. Sandford, Woodhouse, North Finchley, third. These were specially attractive. In class 16 for a vase of Pompons arranged with foliage for decorative effect, the winners were: First, Mrs. S. North, Broughton Lodge, Shepherd's Hill, N.; second, Mr. D. B. Crane, Woodview Terrace, Archway Road, N.; third, Mr. S. Foster, Tenderden Hall, Hendon.

Mr. D. B. Crane was to the fore with a vase of a dozen sprays of Chrysanthemums, showing richly-coloured flowers; the second and third places going to Mr. G. Saunders and Mr. A. Jones respectively out of seven lots. In class 17, for three buttonholes, two gent's and one lady's, the honours were divided by Mr. J. Callingham, gardener to H. Harmsworth, Esq., North End Place, Hampstead, who led; Mr. T. L. Turk, second; and Mr. C. H. Martin third. Nine entered. For a hand bouquet of Chrysanthemums, Mr. E. H. Chitty, Cholmeley Lodge, Highgate, beat Mr. G. Saunders, and third out of five came Mr. D. M. Oliver, 97, Tollington Park, N. Mr. T. L. Turk and Mr. J. Adams were placed in this order for two vases of blooms, and these were certainly decorative. Mr. H. Rand, of 106, St. John's Road, Upper Holloway, led in class 22, for three buttonhole bouquets. There were seven entrants.

Four contested their skill in arranging a centre piece for dinner table decoration; but here Mr. Crane was not to be beaten. Mr. Halsey came second, and Mr. A. Sedgwick third; all were creditable and very pleasing.

Mr. G. Impey beat Mr. J. Brookes for the twenty-four Japs., and third, Mr. J. Sandford; but none of the newer varieties were seen. These were fine collections. In class 47, for twelve Japs. and twelve incurveds, Mr. Turk was premier, and Mr. J. Adams followed second. Mr. Turk also led for twenty-four Japs. in eighteen varieties in class 25; Mr. C. J. Webber succeeding as second; and third, Mr. S. North.

Seven entries of half a dozen Japanese blooms each, made a fine show for class 32, the leader being Mr. W. J. Bennett, gardener to J. B. Braithwaite, Esq., The Highlands, New Barnet. His set included G. W. Palmer, *Chenon de Leché*, Mme. de Blanche, Gustave Henry, Lily Mountford, and Le Grand Dragon. Following came Mr. G. Impey and Mr. A. Jones in this order. Six were forward for the half-dozen of one variety; the leader being Mr. J. Kirkwood with Mrs. G. Mileham; second, Mr. J. Brookes with the same; and Mr. Bennett third with Mrs. Coombs.

Messrs. G. Saunders and H. Stonebridge were so placed for a specimen trained plant, and Mr. Stonebridge was the only exhibitor of four trained plants. Mr. G. J. Bone, of Calverly Grove, Upper Holloway, staged six nice Japs. in class 56, and was also first for the twelve in class 53. The only noteworthy collection of Anemone-flowered varieties in the show came from Mr. J. Sandford, in class 37. For six blooms of one variety of incurved, the order ran: First, Mr. J. Kirkwood, with *Globe d'Or*; second, Mr. J. Sandford, with Chas. Curtis; and third, Mr. H. Currell with *Jeanne d'Arc*.

Grapes were staged by four competitors. Mr. J. Sandford, of Woodhouse, was first for three bunches of black Grapes, and Mr. Kirkwood second. The collections of vegetables were not judged at 1.30 when our notes were concluded.

## Young Gardener's Domain.

### Duty.

The chilly nights of autumn will soon be with us again, and the thoughts of many a young gardener will be turning, perhaps with not altogether pleasurable anticipation, towards what cannot at any time be said to be the most attractive of the numerous duties he is called upon to perform, namely, that of stoking. "To take turn on duty," or "Fires every alternate week"—phrases so often noticed in advertisements—are not presumably

inserted as inducements, but with the object of warning the intending applicant for employment of what he may expect.

Most of us at some time or other have probably come across the kindly and sentimental old gentleman who will smilingly say that a gardener's life must be the happiest imaginable. He will talk of the lovely flowers and the charming trees, and will wax eloquent on the unparalleled opportunity the horticulturist possesses of observing and admiring the same, and of reflecting on the manifold wonderful and glorious works of Nature. (This reflecting process, by the way, should be carried out when one's employer is not looking.) But there is reason to believe that many a young gardener, as he has gone his rounds on a cold winter night, thinking of his colleagues seated round the bothy fire, or of the concert or party he might have enjoyed had not the inexorable night duty stood in his path, has reflected, not without reason, that in spite of what the old gentleman has said his occupation is not altogether a continued round of pleasure. It must be admitted that making up the fires, especially where a good heat is to be maintained and the weather is cold, and the thermometer, with shameless obstinacy, refuses to indicate the temperature it ought, is not a job to be envied. The average gardener, however, soon learns to become a bit of a philosopher, and to look forward to his turn at the fires with equanimity, if not with eagerness, as something that has to be done, and to find out that grumbling will shovel no fuel on, and complaints pull no clinkers out.

There are, of course, fires and fires, as well as stokers and stokers. Happy is the gardener at a place where the heating apparatus throughout is of modern construction compared with those of his brethren whose lot it is to have the care of furnaces erected when the principles of heating were not so well understood as they are now, and the convenience of the stoker was not considered at all. He who has never had to make up a fire where the furnace door was so small that if, after becoming dexterous by practice, he could put on one-fourth of the fuel he shovelled up he thought himself lucky, he who has not taken healthy exercise walking backwards and forwards, shovel in hand, because some antediluvian constructor of stokeholes laboured under the delusion that the proper place for the fuel was as far away from the fire as possible, or has never skinned his knuckles owing to the restricted space allowed for the manipulation of his fire-irons, or beheld some morning, after a night's rain, a flood below, causing him to ask himself whether his employer has taken it into his head to provide his gardeners with a swimming-bath, has not had his full measure of experience in the matter of stoking.

It is strange what one man can do in the way of firing compared with another. While one will manage to maintain an equable temperature with little apparent effort, another, with infinite labour, with poking and clinkering, and a vast expenditure of fuel, will not do half so well. It may not be possible for anyone, however clever, to keep a house at exactly the same temperature to within the proverbial "half a degree," but bad or good stoking is not without its effect on the plants, an effect of which they would surely not be slow to express their appreciation or the reverse, were they only able to speak. It does not require a very great flight of fancy to imagine a fine *Anthurium* remarking to a neighbouring *Gardenia*, "Well, Jones is on duty this week, and we can depend on being comfortably warm all night; I only wish he were on all the year round." Or to picture a *Dracæna terminalis* observing to its friend, the *Stephanotis floribunda*, "H'm, Brown making an ass of himself at those fires again; I wonder whether we shall be scorched to a cinder this time or frozen almost to death. He seems to think we plants have no feelings."—A. W. D.

### TRADE NOTE.

#### Dissolution of Partnership.

The firm of John Laing and Sons, nurserymen, Forest Hill, has been dissolved by mutual consent, and the business will in future be carried on by John Alexander Laing.

#### An Insect Exterminator.

New preparations for use against insect pests are continually being brought to our notice, and we have here to acknowledge the receipt of a tin of Valls' Beetlecute. This is a white, refined powdery substance, reputed to be an infallible exterminator of beetles, cockroaches, ants, and insect pests; and any cheap preparation that will banish and overcome the pests we specifically name, should indeed be accorded a welcome trial. "In the glass houses and gardens of the Royal Botanic Society, Regent's Park, London, Beetlecute has been most successful, not only in the destruction of beetles and cockroaches, but in the complete extermination of ants." The sole proprietors are Messrs. Valls and Co., and supplies are furnished through their agents, Messrs. Burgoyne, Burbidges, and Co., 12 and 16, Coleman Street, London, E.C.

### Hardy Fruit Garden.

**PLANTING FRUIT TREES.**—The earlier trees and bushes of all kinds of fruit can be planted now the better. If the soil has been judiciously prepared to suit the different kinds of fruit, the work of planting may be expeditiously carried out, and a good start made towards a free and vigorous growth next season. There are great advantages in autumn planting. The soil is usually in such a suitable condition as regards warmth, moisture, and fertility, also workable conditions, that roots have a chance of forming some new fibres before the winter. This is an important help for next spring, when growth will start away vigorously.

**THE SOIL.**—The best must, of course, be made of the existing soil in the position where the trees are to be planted. Soil can always be deepened, and this must be done, the average depth most suitable as a run for the roots being 2ft. In light, dry, stony positions more may be necessary. A shallow soil, that is, one consisting of not more than a foot in depth of fertile material, must be removed to that depth, and the spit below either broken up and manured or removed, replacing with good loam, which is neither very light nor absolutely heavy.

**DRAINAGE.**—Breaking up the bottom spit of soil is generally a good method of draining, but only acts well in a naturally drained soil. Water-logged ground must be drained. Large plots or quarters should have an arrangement of pipes with a fall to a main drain having a proper outlet. Stations where trees are to be planted may, if found to be very wet, be simply drained by placing a layer of rubble at the bottom of the hole, covering with turf grass side downwards. Some positions may be improved by planting on raised mounds from which much of the superfluous moisture can readily drain away.

**MANURING.**—In preparing the soil the question of manuring comes in. Good, fertile soil which will grow good vegetables, as a rule, needs no addition of manure. It is best not to apply it for Apples, Pears, and all stone fruits. The latter need a soil charged with calcareous or mineral matter. In a rich soil, too, strong growth will result, which will cause a difficulty in management without frequent lifting and replanting of the trees.

**SELECTION AND TREATMENT OF TREES.**—The importance of securing good specimens of whatever form of tree is to be planted is obvious. This matter will be assured if the trees are procured from the reliable fruit nurserymen, who not only send out excellent trees, but pack them so that they suffer only a minimum of injury by the removal. When the cultivator receives them the after responsibility lies with him as to their treatment. It is desirable to unpack them at once, providing the weather is mild. Prune away all damaged roots to sound parts, and carefully lay them in the soil until the trees can be permanently planted. The object is to keep the roots from drying, especially the youngest fibres.

**PREPARATION OF HOLES.**—Proper planting, which includes the careful arrangements of the roots, has a considerable influence in the after growth and ultimate success of the trees. Deep planting is not to be recommended, hence the holes for the reception of the roots should be thrown out shallow, but of a width commensurate with the length of the roots when spread out horizontally. The base of the holes may be raised a little in the centre, making firm.

**PLANTING.**—On placing the trees or bush in position, equalise the roots all round as far as possible, and do not place the stem lower than before. Where the roots are thick and numerous divide them into layers, covering each layer with fine soil mixed with some burnt refuse, which should be scattered over from the stem outwards. This prevents the ends of the roots being turned up, which might be the case if spread at haphazard. The upper layer of roots ought not to be buried deeper than 3in. Make the layers of soil firm, not, however, by treading heavily, thus injuring the roots. Pressing down the soil and working it well in among the roots is the best method.

**STAKING.**—Immediately tall standards, or any form of trees which require support, are planted, stakes must be fixed and the stems tied. This is necessary to prevent wind rocking the trees about, displacing the roots, and preventing the establishment of the trees. Cloth or sacking may be wound round the stems, and the trees secured with strong cord or tar twine. Wall or espalier trees must not be securely tied at first, but loosely held in position, so that the soil and the trees may settle together. It is really best not to permanently secure until spring, by which time the soil will have become consolidated and the trees firmly settled in position.

**MULCHING.**—A winter mulching acts beneficially in preventing frost reaching the roots. It is not intended the first season to apply a mulching for the purpose of fertilising the soil, as this is not required. Therefore the material used should be loose and light rather than heavy and compact. Half-decayed manure is as good as anything. Spread it as far as the roots extend to the thickness of 3in.—EAST KENT.

### Fruit Forcing.

**CHERRY HOUSE.**—The trees having cast their leaves should be pruned. Cut back to within an inch of the base shoots which were made during the summer and stopped at the fifth joint. This applies to all spur growths, but the extensions and growths for forming branches to furnish the trees should not be shortened unless they have reached the extremity of the trellis, or when it is necessary to multiply the branches another season. The house should then be thoroughly cleaned and the trees washed with a tepid solution of paraffin emulsion, 4oz to a gallon of water, adding 3oz of sulphide of potassium, then limewash the walls with best fresh lime. Train and tie the trees to the trellis. Clear away all prunings and other matter. Remove the loose material, whether mulchings or soil, on the border. If the roots are near the surface and fully occupy the soil, a light pointing over may be all that is necessary prior to top-dressing with an inch or two thickness of fresh loam; but no opportunity should be lost of removing inert soil and changing it for fresh turfy loam of a calcareous nature. The roof lights being off, they need not be replaced until the time of starting or the approach of severe weather. Under fixed roofs attention will need to be given the borders for watering, keeping them evenly moistened, ventilating the house fully up to starting.

**VINES—EARLY FORCED IN POTS.**—Where thin-skinned Grapes are required in March and April the Vines should now be placed in position on loose brick pillars, so that the rims of the pots will be slightly above the edge of the pit, and this being filled with Oak, Beech, or Spanish Chestnut leaves they will give out heat and moisture steadily through the early stages of growth, and rich stimulating food from their decay during the swelling of the fruit, when it requires all the support that can be given. Take care that the heat about the pots does not exceed 70deg to 75deg, supplying water only to keep the soil moderately moist, as a wet condition of the soil does not favour speedy and healthy root action. Allow the canes to fall into a horizontal position, over the fermenting material until they have broken, but not permitting them to rest upon the moist and warm bed. Syringe the paths, walls, and canes two or three times a day, but sufficiently early for the last time each day to allow of the canes becoming fairly dry before nightfall. Maintain a temperature of 55deg at night and 60deg to 65deg by day, with a free circulation of air at and above that temperature, and close early in the afternoon.

**LATE HAMBURGH HOUSES.**—The atmosphere in which bunches of thin-skinned Grapes are hanging cannot be too carefully attended to, as the berries are very susceptible to injury from excessive moisture, while if kept too dry and warm they are liable to shrivel. A gentle movement of the atmosphere will prevent the decomposition of moisture on the berries, and where ventilation cannot be given, a little warmth in the hot water pipes will keep the air in motion, and the moisture will be condensed on the glass so long as the external air is cooler than that of the house. A steady temperature of 50deg, with a little warmth in the pipes, and liberal ventilation on fine days, will suit the Vines during the fall of the leaf, when, unless the house is well adapted for keeping them, the bunches may be cut, bottled, and placed in the late house or a cool, dry room. The border must be kept fairly moist, or the Grapes will shrivel, even while the leaves are on the Vines.—ST. ALBANS.

### Trade Catalogues Received.

- James Cocker and Sons, Rose Specialists and General Horticulturists, Aberdeen.—*Roses, Plants, Shrubs, Fruit Trees, &c.*
- Damman and Co., Seed and Bulb Merchants, San Giovanni a Teduccio, near Naples, Italy.—*General Price List.*
- M. Herb (ex. Herb and Wulle), Naples, Italy.—*Novelties for 1903.*
- Jardins Correvon, "Floraire," Chêne Bourg, Geneva, Switzerland.—*Catalogue of Plants.*
- Harlan P. Kelsey, Highlands Nursery, Kawana, N.C., and Tremont Building, Boston, Mass.—*Hardy American Plants.*
- John Peed and Son, Mitcham Road, Streatham, S.W., and Roupell Park Nurseries, West Norwood, S.E.—*Hardy Perennial Plants, Florists' Flowers, and Alpines.*
- Pinehurst Nurseries, Pinehurst, North Carolina, U.S.A.—*Wholesale Trade List.*

\* \* All correspondence relating to editorial matters should be directed to "THE EDITOR," 12, Mitre Court Chambers, Fleet Street, London, E.C. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense.

### Plan of a Bothy—Competition.

"Well-wisher" promises a first prize of £3, and the Editor supplies a second prize of £1.

The rules of the competition are as follows:—The plan, drawn to scale, must not exceed 7in broad by 7in deep, and must be clearly defined on stout paper. The plan must provide suitable accommodation for six men, and the cost of the building ought not to exceed £200 to £220. A statement of the general items of cost should accompany the plans, together with any written comments thereon. The competition is open until Christmas, 1902, by which date all plans must be in the hands of the Editor. The sender's name and full address should be enclosed when sending the plan, and the sender will alone be held responsible for it.

**NAMES OF APPLES (Susséx).**—The reply was intended for you, "X. Z. A."

**RULES FOR A VILLAGE FLOWER SHOW (R. L.).**—We have forwarded to you what may be a useable or adaptable set of rules for a society such as yours.

**CONTRIBUTION OF 2s. (J. P.).**—We received the 2s. and handed it to Mr. B. Wynne, secretary of the Royal Gardeners' Orphan Fund, who has returned a receipt.

**SECRETARY U. H. B. AND P. S. (E. Smith).**—Mr. William Collins, 9, Martindale Road, Balham, London, S.W., is secretary of the United Horticultural Benefit and Provident Society.

**FERN FOR STAND IN NORTH WINDOW (L. C.).**—It is not possible to determine the name of a Fern from a single division of the fronds, but we think it is *Cyrtomium falcatum*, which is nearly if not quite hardy, and as such would be suitable for a stand in a north window. *Asplenium flabellifolium* is a charming small Fern for suspending in glass cases, but in the position you name it would not succeed in winter. It requires to be kept from frost.

**AJUGA REPTANS PURPUREA PROPAGATION (C. P. B.).**—It has dark purple bronze foliage, and forms a good contrast to Golden Feather Pyrethrum, and is the best in spring, being very valuable for spring bedding. It is propagated by cuttings of two joints and the growing point inserted in sandy soil, kept moist, and shaded from sun; or they may in summer, or even now, be put in on a north border, but would root at this season more freely in a frame. Plants for spring bedding ought to be struck early in summer, and should be nice plants by autumn. It is perfectly hardy.

**PLUM TREES UNFRUITFUL (Amateur).**—The trees would be best lifted as soon as the leaves turn yellow and begin to fall. Take out a trench about 3ft from the stem, cutting off all roots and lift the trees with the roots in the space towards the stem, cutting off any roots that go down. After putting some soil under, replace the tree and fill-up, treading the ground firmly. The trees should be kept rather high, the uppermost roots about 6in above the surrounding ground level, and cover them about 3in deep with fresh soil, making firm, and mulching over the roots with littery manure. It is not desirable to defer the pruning until spring with a view to protect the blossom from frost. If summer pruning were properly attended to, very little winter pruning would be required.

**EDGING PLANTS FOR BORDER ON LAWN (M. H. M.).**—For a permanent edging to a border on grass, Ivies of the green kinds would not be suitable, as they would not contrast unless you had the border raised, and then they would answer admirably. The small-leaved kinds are most suitable, as *Hedera Donolieriensis* and *H. taurica*. The best silver is *H. Helix elegans*. *H. Helix foliis variegatis* is also good. The edging may be raised with stones, over which the Ivies will run and cling to, and soon form a close edging. The *Euonymus radicans variegatus*, with green leaves broadly margined with white or silver, is excellent for edging; *E. flavescens*, with leaves of a deep chrome yellow, is also good, and might with cutting be kept to the height you require, it being of free growth, but compact. The variegated Thymes are desirable edging plants; one variegated yellow, *Thymus citriodorus aureo-marginatus*; and the other white, *T. variegatus*.

**NAMES OF PLANTS.**—*Correspondents whose queries are unanswered in the present issue are respectfully requested to consult the following number.* (N. T.).—1. *Quercus rubra*; 2. *Quercus cerris*; 3. the Black Walnut, *Juglans nigra*. (J. T.).—1. *Polygonum polystachyon* (syn. *P. molle*); 2. *Tropaeolum Fireball*; 3. *Calceolaria Burbridgei*; 4. *Crocus speciosus*. (N. B.).—1. *Oncidium Forbesi*; 2. *Cattleya Lodigesi*; 3. *Oncidium incurvum*; 4. *Vanda caerulea*; 5. *Phalaenopsis amabilis* var. (B. B.).—Next week. (W. M.).—Currants badly infested with mite; destroy them by burning.

**NAMES OF FRUITS.**—*Correspondents whose queries are unanswered in the present issue are respectfully requested to consult the following number.* (C. N.).—1. Ribston Pippin; 2. Gascoigne's Scarlet Seedling; 3. Reinette Van Mons; 4. Baumann's Red Reinette; 5. Manx Codlin; 6. Warner's King. (Enquirer).—1. Cellini Pippin; 2. ditto; 3. Cox's Orange Pippin; 4. Adam's Pearmain; 5. Reinette de Canada; 6. Benoni. (Thirty Years' Subscriber).—1. Cox's Pomona; 2. bad specimen, not in character; 3. Dutch Mignonne; 4. Duchesse d'Angoulême. (J. P.).—1. Bielo Borodowka; 2. King of the Pippins; 3. Blenheim Orange; 4. a seedling form of No. 3, of which there are many about the country; 5. Scarlet Nonpareil.

| MEANS ...     |                    | 47.5                    | 46.0      | 57.7      | 38.7      | Total. 0.22                           | 49.6      | 52.0           | 53.7           | 31.5                         |

The weather during the week was rather dull and heavy, with intervals of bright sunshine. Small quantities of rain fell on four days.

## Storing Mangolds.

The season has been too cold and late for the Mangold crop, and the promise of a heavy weight of roots has not been realised. The plant is a good one, but the Mangolds are not big enough to fill the carts quickly. The tops are still very green and full of growth, and if we were sure that frost would not intervene we might leave them to grow until Martinmas; but experience teaches that as November approaches severe frost does put in an appearance, and therefore if we wish to make the crop safe we had better take them up at once.

The Long Red and Tankard varieties should be taken up first, as they not only ripen first, but stand more out of the ground, and are, therefore, more liable to injury. Long Reds are much less popular than they were; it is seldom we see a piece now. One was observed the other day, and it presented a most promising appearance to a casual glance. A closer inspection, however, revealed the fact that the plot of Globe Mangold adjoining was decidedly of heavier weight, had less top, was deeper in the ground—in fact, better altogether.

The usual way to take up Mangolds is to pull the root up, cut the top off with a knife, leaving the roots untouched. The Mangolds are then carted into a pit, or pie, which, if the roots are ripe, may be made 10ft or 11ft wide. Whatever the bottom width they must be thrown well up, so as to get the ridge of the pie as high and steep as possible. This is important, for it is not always convenient to spare good Wheat straw for storing the Mangold, and if we have to use Barley straw or bracken or grass from the ditch banks, though these materials are good enough to keep frost off, they do not make good thatch, and if we let the roots get wet during the sweating process, we might have our pies falling in, and heaps of corruption instead of sound and valuable roots. In the interests of dryness it is advisable to soil the pies at once, but a 2ft opening should be left along the ridge until all sweating is over.

Taking Mangolds up is generally done by piecwork, 9s. to 11s. per acre being given for pulling them and filling them into carts. They are generally pulled, the tops cut off, and left in rows for carting, four rows being thrown into one. The cart comes between two of these quadruple rows, and is filled from each side.

Another system is to throw the pulled Mangold into small heaps, and then cover the heaps with Mangold leaves until it is found convenient to cart them to the pie. This is more expensive if labour for the pulling and heaping does not include the filling of the carts as in the before-mentioned system. The men would prefer to fill the carts rather than heap them at the same price. Straw is plentiful this year, so there is no reason to grudge a good covering to the Mangolds. They are as susceptible to frost and injury as Potatoes, but not so liable to damage from wet, so a good thick and dry covering is more material than thatch as a protection.

As the season has been cold and damp, and the soil is now of a decidedly sodden character, it is from every point of view desirable to waste no time in storing our Mangolds. The crop is not heavy, and it might greatly increase during the next month if frost kept off; but a severe frost might be so fatally injurious to the finest crop as to make us very wary of running risks of that kind.

### Manurial Waste.

Farmers, and even the best of them, are often slow to take advantage of opportunities which come in their way. For instance, we know of a nuisance in a neighbouring parish, and a dreadful nuisance it is—an open drain beside a highway, the said drain reeking with sewage, and without fall to clear itself. This is in the area of a small urban district, and the farmer on whose frontage the drain is does not like the expense of cleansing it, which the Urban Council forces upon him because the ditch is upon his land. He keeps on cleaning out the ditch very unwillingly, and leaves the material removed to be carted away by the first comer. We will not enter into the question of responsibility for cleansing such a drain; but surely no sanitary authority has a right to use a wayside ditch as a settling tank and saddle the occupier of the adjoining field with the responsibility for keeping it cleaned out. But we are concerned as to the ineptitude of a tenant to take advantage of opportunity afforded him.

A tenant in the position we have sketched might have the manurial value of the sewage of the parish at his disposal, and be paid for disposing of it; and if we brand such a man with the badge of thriftlessness, what must we say of those thousands of farmers who allow the liquid manure from their yards to pass down the parish drains and aid in the contamination of our watercourses and rivers?

The urine of the horse is far more valuable than its dung, but we take great, and we might say misapplied, care of the latter, whilst the former is swilled out as a nuisance rather than as a valuable asset. The true value of peat moss dust in preventing waste of this description has yet to be demonstrated. If this material were used generally in the gutters of cow-houses and stables it would absorb the urine and with it the large proportion of ammonia which it contains, and this, instead of being wasted, or practically so, could be applied by the medium of the peat moss dust to the land, which every day becomes in greater need of it.

Our rivers are polluted every day with matter which would be invaluable to the land. We import immense quantities of Wheat, flour, and feeding stuffs from abroad. If the net manurial value of these articles were not wasted the land of Great Britain should be growing more fertile every day; but the agricultural returns and the "Times" reports do not say so. On the contrary, they show that large quantities of artificial manures are purchased to make up deficiencies by waste of natural manure. It is ammonia we lose, and if we paid more attention to the saving of the ammonia contained in the urine of our horses and other stock we should have less need to spend money in the purchase of sulphate of ammonia and nitrate of soda.

### Work on the Home Farm.

As is often the case after wet and late harvests, there are frequent cases of dispute as to the proper delivery and dressing of Wheat and Barley, and as long as farmers will persist in weighing up their corn from the machine tail such disputes will prevail. As the land varies so does the sample, and to get a satisfactory sample to sell by, portions from the different parts of the field must be well mixed and dressed, and a sample taken from the mixture. Then if the whole bulk is well turned over, mixed, and then dressed, the sample should be representative of the bulk, and no occasion for a dispute can occur. It is wise policy for a farmer to keep a sealed duplicate of each sample he

offers. A factor may buy a sample slightly out of condition, and if he does not sell it for a week or ten days it may very easily, by constant showing and handling, become fairly dry before a re-sale takes place. His customer buys what he considers a dry sample, and naturally objects to have the bulk delivered to him out of condition, and the fault is saddled upon the grower, who generally has to submit to a reduction of the agreed price. This is one more of the penalties for being made use of by the middleman. If farmers were determined always to sell direct to millers or maltsters they would always be able to deliver their stuff immediately, and cases like the above would not occur.

We got the cultivator through the Wheat stubbles, but pressure of other work has prevented anything like clearing, even had the weather been favourable, and with Mangold storing to do and some Potatoes to sort for market we shall hardly get our fallows dressed now; fortunately they are particularly clean, and will not suffer from the neglect. We shall not be able to plough them down much before December.

No Wheat drilled yet! It has been too wet to drill the Clover ley, and the Potato land is not ploughed yet. Many Potatoes still remain in the ground, which is becoming very soft and muddy, and very disagreeable to work amongst. There is a rather healthy demand for good users at 55s. to 60s. per ton, and the smaller growers are selling and delivering as they lift them. This makes the labour difficulties worse, and threshing is frequently prevented by lack of hands.

There has been a strike of Irish Potato pickers. We mentioned a month ago the excellent effect spraying had on a field belonging to a neighbour. This field caused the strike, the crop being so great that the men could only earn half the wages earned by men working on other farms. The strike is settled by the promise of a bonus, but the men are not quite satisfied yet.

## Irrigation in Australia.

The work of extending irrigation in the highland regions of inner New South Wales and Queensland is going steadily on. Wherever artesian wells are yielding a large supply of water there are to-day fertile oases amid the deserts of unproductive land. There is one peculiarity about irrigation in Australia: very little of it is derived from running streams, and irrigation improvements are, therefore, very different, for example, from those in Egypt and California. The reason why the rivers are not very useful for irrigation is that the tributaries lose all, or a great deal, of their water by evaporation or percolation before they reach the main streams. The result is that the Darling, Murray, and other important rivers contain so little water during the summer and autumn months that it cannot be used to flood irrigation channels.

We should never have heard of irrigation in Australia if it had not been for a most interesting discovery. It was found that the water which disappears from the many mountain regions is not by any means all lost through evaporation. A great deal of it sinks through permeable strata of the rock, and collects deep under the ground in artesian reservoirs. It needs only to be brought to the surface to cover many areas with fertility. When it was found that a large part of the dry regions of Australia have immense resources in underground waters, the people began to sink artesian wells. The work began in 1881, and is to-day being pushed more vigorously than ever. The greatest centre of artesian wells is a vast region in Queensland, north of the sources of the Darling River. Along a line which extends north, north-west, south, and south-west, in the form of a half-circle, are over 360 wells, ranging in depth from 100ft to over 3,000ft. The quantity of water from these wells is variable, the majority of them yielding at least 100,000 gallons each every day. Some of them yield one, three, and four million gallons a day. There are many wells in other parts of Queensland.

In New South Wales the wells are much fewer in number, though there are several important centres, particularly at Bourke and Winton, where hundreds of thousands of sheep and cattle obtain their water supply from these artesian wells. In Victoria, South Australia, and West Australia, the boring of wells has scarcely yet begun on an important scale, though in the past two or three years water has been obtained in copious supply at a number of points. But in Australia there is nothing like the large areas of land restored to fertility that may be observed throughout Southern California. In fact, the artesian waters are used more to supply the millions of sheep and cattle with the drink they must have, or perish, than to spread over the grain fields and fruit farms. It remains to be proven whether vast areas of the continent may be reclaimed for farm crops by filling irrigation ditches with artesian supplies. At any rate, the boring of these wells has opened enormous areas of the interior high lands that were formerly useless to the successful pursuit of stock raising.

### How Orchards are Formed.

F anyone has doubts about the future of hardy fruit culture in this country he may have them dispelled by looking round and observing the young orchards and plantations that are springing up on almost every side. I do not mean to say that they will be found everywhere, for in some counties scarcely any movement is being made, but I do not take this as being a bad sign, because fruit culture is, and must be, confined to certain localities. I have no patience with that incessant cry of plant, plant, plant, irrespective of soil and situation, and people know better than to believe that the growing of fruit necessarily means riches. We do not want the whole country to be turned into a vast orchard, it would not be possible if we did, but it is on the extended planting in districts naturally adapted for fruit culture that the future of this important industry depends.

Because an Apple or Plum tree does well in a certain place it does not follow that another branch of cultivation should be done away with in order to grow fruit on an extensive scale. We might as well try to upset the whole system of agriculture, because, broadly speaking, fruit may be included in this branch. Some people in Kent, for instance, keep cows, but it would be useless to go in for dairy farming such as it is practised in the Midlands and elsewhere; and it is the same the country over. Nature has settled the question by rendering one part of the country suitable for dairying, another for grazing, a third for sheep, a fourth for fruit, and so on. There is no need for any revolutionary methods, but let everything be done in each district to improve the cult of whatever particular crop or agricultural industry that locality may be naturally adapted for.

READERS are requested to send notices of Gardening Appointments or Notes of Horticultural Interest, intimations of Meetings, Queries, and all Articles for Publication, officially to "THE EDITOR," at 12, Mitre Court Chambers, Fleet Street, London, E.C., and to no other person and to no other address.

I am writing from Kent, than which there is no county in England better suited for growing a variety of fruit, and in none, perhaps, are better methods practised by market growers, in spite of the fact that everything is not as it should be even here. When journeying through the Cherry-growing districts I observe young orchards being planted year by year and coming into bearing. If this were not so, what becomes of the thousands of trees that are annually sent out from our leading nurseries? In other parts where the Apple is pre-eminent—notably in the Weald of Kent—there is the same display of young orchards; and fruits which are necessarily of shorter duration, such as Gooseberries, Currants, Raspberries, and Strawberries, come and go, but in its season the operation of planting is ever going on, and the total area of land under fruit is steadily increasing. You hear the Kentish farmer talk hopelessly of corn-growing, and he has grave doubts about the ultimate profits of Hop-culture, but in spite of the fact that he has seasons of dearth and seasons of glut, he says little about his fruit that is uncomplimentary, and steadily goes on planting.

In the case of our hardy fruits—Apples in particular—we are apt to saddle a good deal of unmerited blame on past generations of planters. We talk of the plethora of worthless varieties still in cultivation, as though their unwelcome presence were the fault of our forefathers, but we haven't the heart to do away with them. But we owe something to our predecessors all the same, for who is there who has a giant matured tree, or an orchard of them for the matter of that, of Blenheim Orange, Wellington, or some other good old Apple, who has not reason to bless the hand that planted them? But this, as Kipling would say, is another story, and it teaches us to be fair in our criticisms of what has been done. We should remember that in the past decade high-class varieties were not so numerous as they are now: a nation at home was not clamouring for first-rate fruit, neither were there other nations over the water thirsting to supply it. The Apples of our grandfathers were good enough for their needs, but times have changed, and if the poor seedling and non-descriptive varieties that are still produced on trees that have long survived the planters, are not good enough for present demands, there is a remedy—they can be done away with; but the cutting down of an Apple tree, be it ever so unworthy, if it still bears fruit, is too much for the courage of many a fruit grower.

At this season of the year, when fruit growers, private and commercial, are making their plans for planting, the moment is opportune for a word on methods, particularly as regards orchard trees. The man who plants a permanent orchard is doing something for posterity, and he should realise the responsibility of this. The next generation reaps the full benefit of his wisdom, and it also suffers through his mistakes. I can give an instance of this. A friend of mine recently purchased a couple of orchards, one planted with Blenheim Orange and the other with another variety. About the selection no fault could be found, and the trees were in a full state of bearing, but the Blenheims though they were planted at orthodox distances apart, had, through their spreading habit of growth, become overcrowded, and my friend was in the dilemma of leaving them to spoil each other or cut away a lot of valuable fruiting wood. The Apples in the other orchard were of an upright and less vigorous habit of growth, and though planted at the same time there was a waste of space between them. You see the point perhaps, if the two varieties had been planted in alternate rows they would have filled the space without any overcrowding, and just as much or more fruit would have been obtained, without the painful necessity of hacking healthy trees about just when they were in a splendid state of bearing.

Considering the number of standard trees that have been sent out from nurseries during recent years, one might think that there was no need for further propagation; but, bless you, they don't all grow. I wonder how much money is annually wasted through planting inferior specimens, and sticking trees into grass land, irrespective of suitability, and taking little or no notice of them afterwards. In the planting of permanent orchards, a useful lesson or two might easily be learned from some of our Kentish growers. I could point out some notable examples to my readers, instances in which there are no haphazard methods, but where the thing is done on practical lines and with a purpose.

To begin with, the proper place to make a permanent orchard is not a pasture, but a ploughed field. The trees

make an infinitely better start in ground that is under cultivation for the first few years, and perhaps no finer examples of young Apples could be seen than those planted in Hop gardens in Kent. After a few years the Hops are grubbed, the ground is laid down to grass, and an orchard is established that remains profitable for more than a lifetime. I am aware, however, that it is not always feasible to plant on cultivated land, and when trees are planted in pasture no grass should be allowed to grow round the stem for the first few years.

In the case of standards, let us do away once and for all with the anxiety to get fruit before we have got a tree. The latter should be the first consideration, fruit will be sure to follow, and in the pruning and general management the idea should be to lay a sound foundation of bone and muscle, so to speak, and there will be no doubt about the resources of the tree in the future. And again, plant good specimens. There is no economy in a cheap Apple tree if it is a poor one, and many notable failures and monetary losses may be traced directly to the mistaken policy of buying at the presumably cheapest market.

When planting an orchard I have little sympathy with planting trees twice as thickly as they should be, with the idea of removing every alternate one when they get crowded. Nine times out of ten they never get removed at all, and the orchard is spoiled; and even if they are, you are put to the painful necessity of destroying trees just when they have arrived at a state of bearing. It is far better to make whatever sacrifice of space that may be necessary at the outset with the sole object of establishing an orchard that will be a credit to the planter and a source of profit to himself and his successors.

Lastly, let me advise everyone to plant good varieties. I need not mention them, for they have been drummed into our ears till they are household words. Their name is legion, but the planter may count on his fingers the sorts most suitable for a permanent orchard, and the way in which this Apple, or that acquires itself in the locality should also be a guide in making a selection. Above all things, let the planter of a permanent orchard remember that he is not planting for to-day, nor to-morrow, but for years hence; and if he works on sound, practical principles he will benefit himself, and his successors will bless him in their day.—G.

#### Stem Vascular System of Certain Dicotyledons.

Mr. Worsdell, in a paper on this subject before the British Association, said his object was to show, from anatomical data, that no hard-and-fast line existed between the two classes of dicotyledons and monocotyledons. The hollow vascular cylinder of the stem of a great number of dicotyledonous orders, if not of all, had been derived from a system of scattered bundles such as was characteristic of the stem of almost all monocotyledons. The flowering-stem and peduncle, as being those parts of the caulome which had undergone least modification owing to the necessities of adaptation to external conditions, exhibited, as a rule, most clearly the primitive structure which in the vegetative parts had become obscured. The axial organs of the seedling, owing to their limited diameter and the small number of leaf-traces concerned in the building-up of the vascular system, could not as a rule possibly exhibit primitive scattered arrangement of the bundles. As the stem increased in height and became more woody, and the leaves smaller and more numerous, the scattered arrangement of bundles in the stem (chiefly a result of the latter being mainly built up of large leaf-bases from which great numbers of pluriseriate bundles entered the axis) gradually became modified into that of a hollow cylinder, which was necessary both to support the bending strains from a tall stem and to facilitate the continuous centrifugal addition of new conducting tissues by means of a secondary meristem. The stems of plants possessing scattered bundles supported bending strains by means of a sub-peripheral sclerotic band, and, in those cases where a secondary meristem was present, increased their conducting tissue by the continuous centrifugal formation of new scattered bundles accompanied by interfascicular tissue. As far as the investigation had gone, the primitive scattered arrangement of bundles could be traced in the stem of about thirty dicotyledonous orders, and no doubt many more would reveal it. In some monocotyledons the scattered bundles had become very peripheral, and even reduced to a single series or row of bundles. In some cases amongst dicotyledons where the scattered arrangement had vanished from the stem it could still be found in the less modified foliage-leaf, especially where the petiole was cylindrical in contour or possessed a considerable diameter. In view of the above facts the author cannot agree with those writers who maintained that the vascular structure of the seedling stem of dicotyledons generally proved it to be primitively tubular in dicotyledons generally proved it to be primitively tubular.

***Odontoglossum crispum*-Harryanum var. *delicata*.**

The flowers are large, with pale coloured segments, white at the base and heavily spotted with chocolate colour; the lip is large and white tipped, also speckled and marked with brown, and has a yellow blotch on the claw. A First Class Certificate was accorded to this novelty when Baron Sir Henry Schröder, The Dell, Egham, staged a plant bearing six flowers, at the meeting of the Royal Horticultural Society on October 20.

**The Week's Cultural Notes.**

In preparing Orchids for their winter's rest the mistake of drying them off too quickly is often made. To properly withstand the drying process necessary to their culture pseudo-bulbous Orchids have to store up plenty of nutriment, and the drying must come afterwards. As long as the roots, then, are sufficiently

active to take up moisture the moisture must be supplied. Naturally the water supply will be limited now, because the atmospheric conditions now obtaining are not conducive to a rapid drying. Nor are the roots active enough to take a full supply, but to dry the plants altogether directly growth ceases means depriving the pseudo-bulbs of a certain amount of stamina that they will need later.

It is far better to over-water a little now and keep the plants drier in spring, as the plants are hard now, whereas in spring there are tender young growths that damp off easily with any excess of moisture. And in plants that shrivel badly in winter the young growths that do start are weakly to begin with, while those from stout plump bulbs are strong and well able to take care of themselves. The shrinkage often noted in pseudo-bulbous Orchids in winter may to a great extent be lessened by attention to their wants now.

Distichous-leaved kinds, on the other hand, like *Phalænopsis*, *Aërides*, *Saccolabium*, and *Vandas* are taking very little moisture now. If the plants are examined the late growing points of the roots will, in the majority of cases, be found to have clouded over.

There is not the same soft spongy appearance there was a month or so ago. This indicates a desire to rest on the part of the plants, and beyond an occasional moistening to prevent the leaves becoming soft and shrivelled, water will do more harm than good.

Especially is this the case with regard to the Moth Orchids. Roots and leaves are exceptionally sensitive, and both are now able to draw from the atmosphere nearly all the moisture they require. The leaves in particular should not have a drop of water near them now, as it runs down to the junction of stem and leaf and rots the latter at the axil. The larger growing members of this section, such as *Vandas* of the tricolor and *suavis* group, large *Angræcums* like *A. eburneum* and *A. sesquipedale*, *Aërides odoratum* and similar subjects, are not so particular. Their roots are stronger, and the nature of the leaf is more adapted to throwing off moisture, but even here only enough to keep them plump and in good condition need be given.—H. R. R.

## Crocus hyemalis.

Less useful in the garden than many of its congeners, the winter-flowering *Crocus hyemalis* may be said to be emphatically a flower for the *Crocus* lover who is prepared to devote a little extra care to secure its flowers. This is due to their appearance in midwinter, a time when we have not only stormy weather as a rule, but also short days with only a brief spell of sunshine.

The former evil may be remedied by the aid of a glass or hand-light over the flowers, but the latter cannot be overcome in our climate. On the other hand, the flowers last longer than if they had daily sunshine, always provided that they are properly protected. Thus such a *Crocus* as *C. hyemalis* is also one for the amateur with an unheated or cool greenhouse or frame, as the corms may be potted, though they must be kept out of the reach of mice, which are serious enemies to the *Crocus* where they are rife. In light, sandy soil it will do well, and, while some recommend shallower planting, I should not think of keeping the tops of the corms less than an inch beneath the surface, and I should prefer a depth of two inches when cultivated in the open ground.

*Crocus hyemalis* is in itself a pleasing although not a showy species, its claims upon our notice lying mainly in its time of blooming and in the quiet and simple beauty of its delicate flowers. Its floral segments are thin in substance, which makes the glass covering in winter all the more necessary. They are yellow at the throat and are white, veined with purple lines towards the base. The handsome variety *Foxi* has, according to Mr. Maw, the outer segments "freckled and suffused with purple," but this is not invariably the case, and individual flowers have frequently the same exterior colouring as the type. The anthers, filaments, and style are all orange, except in the variety *Foxi*, which has black anthers, a feature which adds greatly to the beauty of this form. The flowers are of medium size, and are very pretty and attractive when open in the sun.

*Crocus hyemalis* has only a limited range in its native habitats, this being confined to Palestine and the Syrian border, and the variety *Foxi* was sent originally from near Jericho.

It appears rather remarkable that the typical *C. hyemalis* is but rarely found in cultivation, while the variety *Foxi* is the one usually obtained if *C. hyemalis* is ordered. I have had it from several sources, both here and on the Continent, and always

with the same result—that *Foxi* was sent. I have, however, this autumn an importation from the north of Asia, and hope that this may turn out the typical form, although the other is perhaps the more distinct and attractive of the two.—S. ARNOTT.

### Transplanting the Pæony.

In nursery catalogues the advice is sometimes given to transplant the Pæony in autumn in preference to spring; and this is very good advice, if one wants flowers. Taken up in the usual way in spring and reset, the plants seldom bloom until the following year. The Pæony starts to grow very early in spring, and this and the loss of some roots in digging check it so much that it rarely flowers as it would have done if undisturbed. If of flowering age, and but little disturbed in the operation, fall planting will not hinder its blooming.

***Odontoglossum crispum*-Harryanum var. *delicata*.**

#### Ryecroft Nursery, Lewisham.

At this nursery Mr. H. J. Jones has an excellent stock of plants this season, better than he has had for years. The flowers most in evidence, and which impressed themselves most favourably, were George Lawrence and Mrs. Harry Emmerton. As seen at Ryecroft, these are perfect. Without describing them at this point, I should like to dot down a few other names of novelties, each of them especially good, as follows: Miss Elsie Fulton, which name is on everybody's lips in the Chrysanthemum world, and yet it is only—but there. Then General Buller (the flower) is as bronzy as the battle-warrior; W. R. Church is good everywhere this season; Madame Paola Radaelli is a mass of beautiful pink and white, the petals broad; O. V. Douglas, the "butter-and-eggs" mixture, will take on because of its soft yellow colour and size; Matthew Smith is intensely rich in hue; Nellie Bean—a new edition of the charming Emily Towers; Bessie Godfrey, which, with Sensation, were perhaps the best of the Exmouth novelties last year, are A1 at Lewisham; while no one can pass by Mrs. Greenfield, the finest thing in deep yellows, or Mrs. Alex. McKinley, which has already drawn forth praises in other quarters. To conclude with, in this select list must be named the gigantic Ben Wells, the superb Lily Mountford, the beautiful yellow Earl of Arran, and, lastly, Master C. Seymour, all of which well deserve a prominent place in collections.

From what I have seen of the shows thus early, there are many exhibitors who do not fortify themselves with the year's novelties, as evidenced by the stands staged by them, and much of the charm of attending the shows is thus lost to those who, like myself, follow the careers of the new varieties from year to year, and find a charm in observing their behaviour under the different meteorological conditions peculiar to each season.

General Buller is a handsome bronzy amber, but rather apt to damp, if one may judge from Mr. Jones' plants. It is one of the largest of the incurving Japs. Miss Elsie Fulton, lately certificated, is certainly a beautiful and somewhat incurving Japanese, of snowy whiteness, but it is very much like two others that might be named. Mrs. J. C. Neville is another large white. Mrs. Harry Emmerton (Bunning) has proved to be a large flower, with smooth, drooping, flat florets, of a deep canary yellow. Henry Stowe furnishes a pure mauve-pink flower, after the Vivian Morel type; Geo. Lawrence, already noted, is spoken of as an amateur's flower, coming well on any bud, but crowns preferably. It is certainly one of the largest and finest Chrysanthemums of this season, and was raised by Mr. Perkins, whose foreman's name it bears. The florets are broad and smooth, bronzy-buff above and red inside.

Nellie Bean is also a large bloom, which, the earlier one gets it, the paler in colour it is, but shades off with age to Emily Towers colour. It is a very fine novelty. Bessie Godfrey is producing massive flowers on quite small plants, in 6in pots. Decidedly it is one of Mr. Godfrey's best, and at Ryecroft it is held in high esteem, where they describe it as "an improved Von André." The centre is of a much deeper yellow than the pale sulphury tips seen in a fully developed flower. One must always find a line of praise for the peerless Miss Alice Byron, whose huge blooms on single-stemmed plants, only 2ft high, and in 5in and 6in pots, were really a sight to marvel at. In passing, one may note a representative of Mr. Jones' Giant Incurved section, namely, W. Neville, which resembles the Baron Hirsch variety in colour. The flower is very regular, large, firm, and well coloured. H. E. Hayman resembles Sensation—intense yellow with crimson flushing. Another easy doer and good sort is found in C. Penford, an improvement on Mrs. J. W. Barks, which it far and away excels in colour. It comes well on any bud.

Earl of Arran deserves more than the passing notice already accorded. It is excellent after this damp season, just as it was a year ago when the weather conditions were different. The flowers are large, canary yellow in colour, and are slightly incurving. Then there are all the Exmouth seedlings here, to wit, Godfrey's Masterpiece, Queen Alexandra, Godfrey's Pride (well spoken of), Godfrey's King, and Godfrey's Triumph, but many of the plants have failed to produce flowers of the requisite size. The foregoing notes mention only a very few of the many choice varieties at Ryecroft, but growers find it quite enough to keep up with all the new comers. Mr. Jones has some excellent new representatives to offer during the coming season, including Miss Mildred Ware, H. Perkins, and Miss Edith Smith.—VIATOR.

#### Manipulating the Petals.

I have been prompted to write a few lines upon the subject of manipulating the petals of Chrysanthemums, especially the Japanese varieties, by a letter recently received from a prominent exhibitor, who asks if I agree with the reflexing of the blooms of Japanese varieties? He goes on to say:—

"I know some kinds are improved in appearance by having their petals turned, and yet, on the other hand, a good many blooms were shown last November entirely out of character."

For the last few seasons I have heard many comments made at shows by visitors and exhibitors, some for and others against the practice. As the subject opens up a moot point, I thought it might be of interest at this season to those interested in exhibition Chrysanthemums. At the outset I would say I am a believer in an exhibitor making the most of his blooms by all lawful means at his disposal. For instance, a variety like Pride of Madford, for example, which has at times a tendency to display florets of an incurved nature might be made all the better in appearance if such florets were reflexed, displaying that rich amaranth colouring that this variety possesses on the upper surface of its florets. I am fully alive to the fact that such an expression of opinion will not meet with universal approval, especially from non-exhibitors, who do not always realise the various points of advantage gained by displaying every bloom to its fullest extent.

My argument in favour of such a proposal is, I think, a strong one. Is there any authority who will say definitely which varieties belong strictly to the reflexed and incurved Japanese section? He, indeed, would be a bold man who would say so. Even in the case of the variety quoted, and which, I believe, receives more manipulation of its florets than any other, is not definitely described by the central authority—the N.C.S.—in their classification catalogue. Quoting from the published description, I find it reads thus: "Large bloom, outer petals recurving, centre incurving." No one will say there is any finality in this, and, therefore, little argument against the practice of manipulating the florets to obtain the finest display of colour. Mrs. Barkley is another popular variety which is subject to much comment, as well as manipulation of its florets.

In producing Japanese blooms of the finest quality it is surprising what culture does towards the display. With some exhibitors, and in particular localities, blooms of both varieties named will be produced in a natural manner, with not a single petal betraying a tendency to incurve, but all displaying the rich amaranth of the one variety and the intense rosy pink of the other. In Edinburgh the exception is to see a bloom of Mrs. Barkley with incurving florets; naturally, the blooms are built up with florets of a reflexed character. Presuming, then, that Mrs. Barkley and Pride of Madford are said to belong to the incurving Japanese section, would it be fair to judge such blooms as are naturally produced in a reflexed manner at a low standard because they do not conform to the ideal of some few persons?

A grave injustice would presumably be done to such an exhibitor. Those who are conversant with the culture of Japanese Chrysanthemums know quite well that it is purely a question of bud selection whether the blooms will be of the desired form or not. I do not agree, though, with clumsy manipulation of the florets. If a bloom is to be presented in an improved form by reflexing artificially its florets here and there an obstinate petal, surely an improvement is effected. Must a bunch of Grapes be staged with here and there a small berry being exposed because they grew naturally? What is right in one exhibit cannot be wrong in another. What is your remedy, then, for clumsiness? I hear someone ask. A loss of points, of course, must follow.

In conclusion, I would say an exhibitor is justified in presenting his blooms in the best possible manner, providing it is lawfully done. There cannot be such a thing as disobeying a rule which has no definition.

In the case of incurved blooms, it is more often a question of incurving them than the opposite. In this section culture is wholly responsible for such defects as reflexing florets. Here we have a definite aim and an ideal. Manipulation is more in the way of arranging the florets than of converting them; more often they require thinning than anything else. Those who hope to win prizes with incurved Chrysanthemums must manipulate the florets in some form or other.—E. MOLYNEUX.

#### Treatment of Chrysanthemum Henry Barnes.

This is perhaps the tallest or most lanky-growing Japanese Chrysanthemum at present in cultivation. A good method to follow is that adopted this year by Mr. Wells at Earlswood, whose plants have been pegged down and trained horizontally. Only about 1ft at the apex is allowed to grow vertically, and the flower opens splendidly, while the plant takes up but little useful space, being placed at the back part of a stage close under the sloping roof of the house.—J.

**English Flowers for the United States.**

On Saturday, October 25, Mr. W. Wells, of the Earlswood Nurseries, Redhill, Surrey, despatched from a dozen to twenty of his finest flowers to an agent of his in New York City, N.Y., per the s.s. Campania. These were sent on trial, first, to see how the blooms travelled, and, second, in order that they might be compared with other flowers at an exhibition where they were subsequently to be staged. It will be interesting to learn what was the opinion of the Americans who saw these flowers.—H.

**Chrysanthemums in Oxfordshire.**

On Friday last, being in the vicinity of Burcote, and having a short time at my disposal, I decided to visit the gardens at The Croft (the residence of J. Randall-Higgins, Esq.), with a special object of seeing the Chrysanthemums, which are always grown well in the hands of Mr. Morris, who is a most capable and energetic gardener: with another essential quality, to win the respect of lovers of gardening, and that is desirability to make your visit pleasant and instructive. A great deal could be written about these large and well-kept gardens which would stimulate many a gardener to renewed energies, and to go and do likewise; but on this occasion I was going "a Mumming," and of the 'Mums I will write.

On entering the first compartment of a newly-erected range of lean-to houses I found a grand batch of bush plants, to supply cut bloom for decorative purposes. Passing through another house I found in the third compartment a grand display of blooms in variety on healthy and vigorous plants, which were effectively arranged. Miss Elsie Fulton, with blooms 9in deep; Graphic, with blooms 12in in diameter; and so on in like manner were many of the blooms of the following varieties: Mons. L. Remy, Mrs. G. W. Palmer, Mr. T. Carrington, Lord Ludlow, Calvat's Sun, Mrs. Coombes, Mrs. White-Popham, Kimberley, Emily Towers, Duke of Wellington, Rev. W. Wilks, Phœbus, Dora Herxheimer, Mrs. W. Cursham, Miss A. Byron, Mutual Friend, and Mrs. G. Mileham. The best of the incurred varieties were Mrs. H. J. Jones, Mrs. R. C. Kingston, C. H. Curtis, Louisa Giles, Mme. Ferlat, Baron Hirsch, Matthew Russell, Globe d'Or, Yvonne Desblanc, and King of the Yellows. Three large houses are required for housing the hundreds of plants grown by Mr. Morris.—S. HEATON.

**Choice Michaelmas Daisies.**

Perennial Asters increase so much in variety that it is absolutely necessary to reorganise the lists annually if the newer kinds are to be added and the collection kept within a reasonable limit. During the last four years many very fine kinds have been added; indeed, almost a revolution has taken place in the habit of growth, formation, and colour of the flower. Thanks to enthusiastic workers in raising new varieties, notably Mr. E. Beckett, Aldenham House Gardens, who has received within the short space of three years eleven Awards of Merit from the Floral Committee of the R.H.S. for varieties of his raising.

The manifest improvement so apparent in the present-day varieties is in the habit of growth; instead of the stiff, erect style, we have now varieties which grow tall, yet graceful in appearance, as they send out side branches from the main stem from close to the ground, these in turn being pendulous and not too thickly placed, giving the plants freedom and blossom in abundance. Given ample space, a magnificent effect can be produced at this season of the year with these plants. To see the beauty and compare varieties, Michaelmas Daisies should be grown in a batch by themselves. Where so many persons make a mistake in culture is by allowing the stools to remain too long on one site, or at least not replanting often enough. For the largest specimens three shoots at the base will suffice. If more are allowed to remain, the growth is weakly and crowded; indeed, I like to replant every year, and if one stout sucker is selected, the plant liberally treated to manure, handsome specimens are easily obtained. As the present is the most suitable time to make new or replant borders, I thought a descriptive list of varieties would be a help to beginners.

For the guidance of planters I give the approximate height of growth. Hon. Edith Gibbs is a seedling from *Ericoides elegans* crossed with R. Parker; colour, pale blue, densely flowered, drooping habit; October, 6ft. Triumph was raised from Coombe Fishacre, growing 5ft high, and flowering abundantly. The blooms are large, pale lilac in

the centre, deepening to rose at the edge, very free and graceful; October. Esther is a cross from Pleiad, of upright growth, 3ft high, densely flowered, lilac or deep pink, distinct and showy; October. Enchantress, 5ft, drooping habit, free and graceful, almost white in colour.

Gloriosa is striking in colour, when unfolding it is white, changing to lilac and then to deep purple with age; the growth is erect, from 2 to 3ft high, very free. Edwin Beckett is a seedling from Cordifolius, having all the free-flowering, graceful habit of growth of its parent, in colour it is bright blue; 4ft.

Ideal is from the same source, with quite small blossoms, pale blue; this is quite one of the most elegant growing varieties we have. Captivation, 3ft, lilac blue, free. Fascination, 3ft, blue; the leaves are small, the cup-shaped flowers have widely set apart florets.

Minnie is one of the most charming varieties yet raised. The colour is lilac, changing with age to a deep rosy shade of the same tint; 2 to 3ft. Grace Darling is an offspring from Coombe Fishacre, having larger flowers than its parent, equally free in production. Hon. Vicary Gibbs, bright pink, upright growth, flowering abundantly from the ground. Admiration has medium sized flowers, of a purple lilac tint colour, excellent; 3ft.

Novi Belgii supplies many desirable varieties of which the following are some of the best. Densus, lilac blue, 3ft; Ella, 6ft, delicate mauve, a charming free flowered variety, with large blooms; Mrs. John Wood, 5ft, free, erect growth, pure white with a yellow disc; Top Sawyer, 6ft, is an improved form of Robert Parker; Esme, 2ft, large blooms, pure white; Mildred, 4ft, soft blue, large blooms, free, a vigorous spreading habit of growth; Margaret Matthews, erect growth, 5ft, very free, flowers simultaneously, pure white, changing with age to purple lilac; Pluto, 4ft, erect, free, round shapely blooms, metallic blue; Nancy, large pale blue flowers 5ft, free; T. S. Ware, 4ft, rosy lilac blue, a distinct colour; W. Marshall, 5ft, pale blue, large and free.

The Cordifolius type are the general favourites, being free flowering, especially showy in a cut state, the colour, soft mauve, predominates in all the varieties. Major has the larger blooms than the type, Albulus smaller, all 4ft high.

*Ericoides* has Heath-like foliage and long graceful sprays of pure white flowers, which for cutting are much appreciated; all varieties of this type grow into charming specimens if given space to develop fully. Elegans is, perhaps, less stiff in growth than the type; Clio has blush white flowers; Acris is a variety quite by itself in habit of growth and colour, growing 3ft high, forming a full rounded head of bloom, lilac purple; Shorti, 4ft, has long graceful sprays smothered with small bright lilac flowers; Paniculatus, W. J. Grant, 4ft, blush white florets, rosy lilac centre, very showy; Chapmani, 4ft, an erect stem with horizontal side shoots, very distinct and free, pale blue.

Puniceus pulcherrimus, 5ft, silvery grey large flowers, with deep yellow centre; Diffusus is an excellent late-flowered variety, with pure white small blossoms, October and November, 5ft; D. horizontalis, syn. Datchi, 3ft, is one of the most striking of Michaelmas Daisies, the small blooms have pure white florets with a deep red disc.

Tradescanti, 4ft, does not open its blossoms until the end of October or November, the foliage is small, and the flowers white; it is excellent for pot culture late in autumn. Turbinellus has large violet-coloured flowers tipped with rose, remaining long in beauty, 3ft.

The Novæ-Angliæ section supply a nice variety of colour late in autumn. Mrs. J. F. Raynor is distinctly showy, rosy crimson, 5ft; Rubra runs it close in colour and is later in opening its flowers; W. Bowman, purple blue, with an orange disc, is an improvement on pulchellus, 5ft.

Amellus supplies useful variety, all being of dwarf habit 1ft to 3ft, carrying large flowers with a prominent yellow centre; Framfieldi is, perhaps, the best of all, it is stiff yet spreading in habit with deep blue flowers which last long in condition either when cut or as growing; Riverslea is perhaps deeper in colour—rich violet blue—than any; Bessarabicus, lilac-blue, is the more robust and free flowering of any of the section; Roseus, as its name implies, is rose tinted.

R. Parker nanus I had almost forgotten; it is worthy a place in any collection. It is simply a dwarf—2½ft—form of the type, in this way useful for the front of taller kinds or in the herbaceous border itself.—E. MOLYNEUX.

## Notes from Chiswick Garden.

When recently walking round the Chiswick Gardens of the Royal Horticultural Society with the superintendent, Mr. S. T. Wright, I questioned him as to his idea of the best Pears for suburban gardens. He said that while the Apple crop in the gardens had been a slight one, that of Pears was better, and he instanced Louise Bonne of Jersey as the best cropper this season, and as one of the very best Pears for suburban gardens, as it is a certain cropper. The earliest Pear at Chiswick was Doyenné d'Été, which is ready by the third week in July, and is earlier still from dwarf trees. Mr. George Bunyard says of this Pear that it bears freely on any form of tree, and is best gathered a few days before it is ripe.

This is followed by Citron des Carmes, which comes in immediately after; and following these in the order of ripening come Williams' Bon Chrétien, Souvenir du Congrès, which is short lived on the Quince stock, but which does well on a free stock or double grafted—Beurré d'Amanlis, Fondante d'Automne (a great bearer and of fine quality), Louise Bonne of Jersey (which many think to be the best Pear grown), Beurré Hardy, Doyenné du Comice (which Mr. Wright regards as "The finest Pear on earth"), Thompson's, Glou Morceau, Winter Nelis, Josephine de Malines, and Bergamotte Esperen as one of the latest. All these had proved good bearers during the past season.

Mr. Wright recommends the foregoing as of good constitution and good growers. For suburban gardens he specially mentioned Louise Bonne of Jersey, Marie Louise d'Uccle, Josephine de Malines, and Winter Nelis, and as doing well on any form of tree—bush, pyramid, wall, or espalier. Marie Louise d'Uccle, though not of the highest quality, is valuable as a heavy and regular bearer; it is an excellent variety for market culture, as it crops freely when other Pears fail. These suit the London district, being of healthy and vigorous growth, and they carry on the succession until March.

The best keeping Pears, in Mr. Wright's opinion, are Easter Beurré, which is of fine quality on a warm soil, and will keep till the end of April. Beurré Rance, which, like the foregoing, should be planted in a warm soil; it is a free grower, and needs root-pruning to induce fertility, and prevent the fruit from cracking; the fruit will keep until May. Nouvelle Fulvie, a good January variety; Olivier de Serres, February and March; and Marie Benoist, January and February; it produces large fruit brown on the skin, and is of fine flavour.

The following were mentioned as good keeping Apples: Newton Wonder, which Mr. Wright regards as one of the best Apples in cultivation, keeping well until April, and strongly recommended for orchard or garden. Foster's Seedling, a recent new variety of dessert quality; said by some to have come from a cross between Blenheim and King of Pippins, though considered by Mr. Bunyard to be a local seedling from Cellini, and recommended by him for small gardens. Chatley's Kernel, a dessert variety which keeps until the end of May; in shape flattish-round, brownish-red with russet spots. Pott's Seedling was named as one of the finest Apples to plant in smoky districts; while Golden Spire and Ecklinville Seedling were named as two excellent varieties for market work in the North of England. New Hawthornden, Stirling Castle, and Lane's Prince Albert were named as two fine varieties for suburban gardens. The two best late keepers are Newton Wonder and Lane's Prince Albert.

Of Apples which have done well up to this year Mr. Wright mentioned Allington Pippin, which he regards as extra fine, and will keep until March if the fruit be not gathered too soon; it does well on a light soil, but the best flavour is found in fruit from trees planted in heavy ground. Duke of Devonshire was also named as good enough for dessert purposes; it is a somewhat old Apple which has come into notice of late years. Adam's Pearmain and Allen's Everlasting are both late-keeping dessert varieties. The quality of Apples, said Mr. Wright, has been poor this season. The better varieties of Pears have not cropped so well as usual this season, but the commoner sorts—Beurré Capiaumont, Beurré Diel, and Beurré Clairgeau—have produced heavy crops.

Plums, generally, have yielded only moderate crops; the best bearers have been Monarch, Victoria, Belle de Louvain, culinary varieties, and Gisborne's, which Mr. Wright named as a dessert variety; the Frogmore Prolific Damson had also given a good yield. But the best dessert Plums had borne but scanty crops.

Peaches and Nectarines on walls had been an average crop; the best three outdoor Peaches for suburban gardens were Early York, Acton Scott, and Barrington. Outdoor Nectarines: Oldenburg, Rivers' Orange, and Dryden. Mr. George Bunyard recommends three of the American Peaches as bush trees, viz.: Hale's Early, Waterloo, and Early Alexander. He remarks:—"The situation must be sheltered, and the soil should be calcareous, rather shallow, and abounding in porous stones (which can be added if needed, or broken bricks would answer), and the

trees should be treated like Plums, and only be watered with liquid manure when they carry a crop; the aim of the cultivator being to get the wood well-ripened. Fruit so grown carries a fine colour, and is very rich in flavour."

Plums for walls in suburban gardens are Early Transparent Gage, Transparent Gage, and Late Transparent Gage; Mr. Wright considers the foregoing to be amongst the very best dessert Plums. He also recommends for growing in the open as bush or

*Puschkinia libanotica compacta.*

standard, or against a wall, Reine Claude Comte d'Atthem's Gage, a delicious late dessert kind, which, for the space of seven years has never failed at Chiswick; and this grown in the open as a bush; it had a great crop when the other Gage Plums were a failure. Truly a Plum to be planted in all gardens.—R. DEAN.

*Puschkinia libanotica compacta.*

This small genus of Liliaceæ, according to Baker's monograph, includes only two species—i.e., *P. scilloides* and *P. hyacinthoides*. They are closely allied to Scillas on the one hand and Ornithogalums on the other, the habit and general appearance of the plants coming much nearer the former. *P. scilloides*, under which is included *libanotica*, typical, the variety illustrated in the accompanying drawing, and also *sicula* figured in the "Flore des Serres," is amongst the most welcome of our early spring-flowering bulbs, coming in early in March and lasting until the end of April, a time when flowers are most wanted. *P. libanotica* is not unlike Scilla in habit, about 6 in high, throwing up two or three radical narrow lanceolate leaves, and sheathing the flower stem a third of their length. The flowers are collected in a loose cluster or corymbose head, a little larger and deeper in colour than the ordinary *P. scilloides*. In the variety *compacta* the head is dense, flowers more numerous, and having a more distinct blue-coloured midrib running up each segment. Dotted here and there on the rockery or mixed border, they look very gay during their season, and we hope to see them treated in the same way as the Croci and Daffodils in the woodlands. Like several other bulbs of similar habit the Puschkinias can also be grown in pots with advantage, and if introduced into the conservatory or greenhouse they are useful for arranging in the front of the shelves or stages. When treated in this way they are preferably grown several in a pot, like the Scillas, for otherwise they do not produce so good an effect.—M.

## Botanic Gardens.

(Continued from page 406.)

The Royal Botanic Garden, Edinburgh, is the next largest to that of Kew, established in 1670 as a physic garden, and consisted of a portion of the Royal Garden around Holyrood Palace, and was occupied by two eminent Edinburgh physicians, namely Andrew Balfour and Robert Sibbald. James Sutherland was appointed to the "care of the garden;" it was stocked with plants from the private garden of Dr. Andrew Balfour, who had for years been collecting medicinal plants, and also from the garden at Livingstone, in West Lothian, the Laird of which, Patrick Murray, was much interested in the growing of useful plants. In 1676 the same physicians acquired from the Town Council of Edinburgh a lease of the garden of Trinity Hospital, for the purpose of another physic garden, and appointed the same James Sutherland to be its superintendent also. This was known as the Town's Botanic Garden.

About 1702 (just 200 years ago) another Botanic Garden was established in Edinburgh, close to the College buildings; this was known as the College Garden, this also was placed in charge of James Sutherland. Thus we see that there were three botanic or physic gardens. Sutherland from the first gave instructions to the students of medicine in the Royal Garden, and received a Royal Warrant appointing him botanist to the King in Scotland, and empowering him to set up a profession of botany in this garden. The Town Council also appointed him to lecture on botany in the town's college, now the University of Edinburgh. We learn that there were between two and three thousand plants in cultivation there (jointly in the three gardens it is supposed); these were the foundations of the present Botanic Garden, which at present consists of fifty-seven acres, but the present site is not that of either of those gardens mentioned, for in 1820 a new piece of land was purchased, and by 1823 all the plants had been removed to it.

When Sutherland resigned a portion of his charge, a new curator being appointed, split the gardens as it were; but after about twenty-five years they were reunited under one keeper and regius professor. They have at Edinburgh a good collection of alpine and herbaceous plants, trees and shrubs, and many plant houses for Ferns, Orchids, insectivorous, economic and other interesting groups of plants. The regius keeper (Professor Balfour) from time to time gives lectures in the gardens, which are free to the gardeners. For about fifty years the regius keeper and professor of botany in the university having been held by the same person, it has become the custom that the students of the university to come to the garden for instruction. The gardens are open from 8 a.m. week-days and 11 a.m. on Sundays until sunset. The plant houses are open from 1 p.m. until 5.30, or until sunset if this be earlier. The museum is also open on Sundays. The herbarium from 10 a.m. until 6 p.m. except Saturdays, when this closes at 1 p.m.

### Glasnevin.

The Royal Botanic Garden at Glasnevin, Dublin, consists of about thirty-one acres, and was established about 1798. It was then divided into the Linnean garden for the scientific botanist who studies the plants systematically, the Cattle garden, the Hay garden, the Esculent or Vegetable garden, the Dyers' garden, and Irish garden. It is further stated the professor gives lectures on the Cattle and Hay gardens for the instruction of farmers, their servants and labouring men, all of whom are admitted to the lecture free. Also separate lectures were given in those days for dyers' instruction and for extending practical knowledge. It was provided with money for its maintenance from the Imperial Parliament and the Dublin Royal Society. Dr. Wade was the first professor, and Mr. John Underwood was recommended to the Dublin Royal Society by the late Mr. Curtis, Editor of the "Flora Londoniensis," "Botanical Magazine," &c., as a fit person to conduct the practical part. Mr. Speaker Foster (afterwards Lord Oriel), was the prime mover in its establishment, and continued to take a great interest during his lifetime.

A catalogue of the plants grown in this garden was published in 1801 and 1802; the collection was very large, and there were then five plant houses. We need not here go into all details respecting the history of the garden. In 1833 Mr. (afterwards Dr.) David Moore was appointed

director, and after his death in 1879 was succeeded by his son, Mr. F. W. Moore, the present director. They have at the present time eight large plant houses, herbaceous ground and tree and shrub departments, and also the experimental department, with agricultural plants, oil plants, kitchen garden plants, dyers' plants, grasses, fibre plants, and pot herbs. Then there is the ornamental flower ground department, a lake or water garden, a botanical museum, herbarium, and library.—ALBERT HOSKING.

## Renewal of Old Fruit Trees.

(Concluded from page 407.)

With old Peaches, Nectarines, and Apricots it is far best to destroy them outright and start with young trees. In all good gardens a reserve of young free trees is maintained, so that a gap can be filled at once by a vigorous, healthy subject of three to five years' growth, which itself is all the better for the check it receives in removal.

In the Society's Journal, vol. xxv., p. 363, a wonderful drawing is given of a large trained Pear tree which was so successfully renovated by rooting the lower branches that the main and original stem could be dispensed with. In other words, the tree first had one, then three sources of nutriment, and finally two.

In all cases new soil should be introduced to the roots. Good, sound, turfy loam is better than heavily manured soil; and if stimulant be necessary it is best supplied as a top dressing.

There is yet another way of dealing with old overgrown pyramid trees. After two years of free growth, as before named, the resulting shoots can be tied into a frame, and made to assume a set form; thus treated they fruit freely, and the branches being secured the fruit is not bruised by the winds.

It should be mentioned that where large trees are headed back the new shoots are very strong, and must be duly nailed in or otherwise secured; and if a second lateral growth should be formed from the lower eyes, it should be pinched at the third leaf to encourage fruit buds to form.

Very old Figs often get bare below, and far too crowded at the top of the wall. These should have the large coarse boughs cut away at the base, and the best of the resulting new shoots be nailed into the wall.

It is a great mistake to let Figs carry too much wood, and they more often suffer from over-manuring than the reverse. In fact, where they root into the vegetable borders it is as well to make a trench 2ft wide and 3ft deep, and fill this with broken bricks, porous stone, loam, and old mortar rubbish. The roots revel in this material, and the trees lay up good, hard, sound, fruitful wood.

Though the Grape scarcely comes under notice in this paper, old Vines can be safely cut back, where the precaution of leading up one or two long rods from the base of the cane has been previously taken. But it must be borne in mind in such cases that the borders often get into a bad state, or that the roots go searching for nourishment in positions too far from the surface, so that the wisest economy may be to make entirely new borders and start with fresh Vines.

In a small garden half the vinery should be taken in hand at a time, but where several vineries are in use, one house can be renewed in a season.

All small fruits, such as Gooseberries, Currants, and Raspberries, so soon bear fruit that old unsightly bushes are best destroyed to make room for new ones. It may be as well to say that Strawberries are of but little use after three years, and new beds should be made annually, so as to keep up a regular series.

Where old trees are to be grafted, the stems should be prepared in February and the new grafts be inserted by the end of March. As the shoots swell very rapidly, the junctions of scion and stock must be carefully watched, or the tying material may cut into the new growth, causing it to be a harbour for insects and making it liable to snap off, and so losing a season. The scions should be cut in February and be laid in the ground half their length deep, in a shady place until wanted for use.

\* Paper read on January 23, 1902, by GEORGE BUNYARD, V.M.H., at the meeting of the Royal Horticultural Society.

## A Sore Point.

I want, with your permission, to tell a little story which many a gardener, I am perfectly certain, could match. For good reasons the hero of the story is chosen from the lowest ranks of the profession, and, as a matter of fact, is more generally known in the locality as the "Minister's man" than as a gardener. His duties include the care of a cow, poultry, pony, bicycles, heating the church in winter, and cooling it in summer, running messages, taking charge of the parish when the minister, poor man! has recourse to Aix-les-Bains or to Strathpeffer, or maybe to the links of Macrahamish or St. Andrews. That the charge is no sinecure either, a short conversation we had together one day we foregathered will prove. After mutual greetings he apologised for being unable to return and show me the manse garden. "The minister's away," he exclaimed, "and I'm gaun yont bye to Maister Johnston's aboot a marriage the morn's night, and about twae corps I've lying in the parish; and the coals are coming in the morn!" These and other matters we philosophically endured as evils that must be tholed, and though James is to everybody else a kind of all-round factotum, in his own eyes he is strictly a gardener. He visits all the gardens in the vicinity, and within easy reach, and his holiday would be sadly incomplete if some strange garden were not inspected before its conclusion. His reports of these inspections are marked by exceeding terseness, and though hardly fit for the horticultural Press, to those acquainted with his definitions they are charmingly complete. If the garden honoured by a visit is described as "no bad, but a wheen weeds about," we gather that things generally are scarcely satisfactory. "A fine place yon, but I've seen maybe better Roses," conveys the idea of an excellent garden, but with no half-dozen Roses quite so fine as the best of his own growing. Satisfaction without alloy is expressed in some such terms as these: "Man, ye should see So-and-so; a grawnd place; beats me wi' Strawberries, and no far ahint wi' Leeks, and I'm no sure but he has me wi' Ingins!"

James, moreover, affects a proprietary air where the garden is concerned, which he seldom does in the case of the other multifarious duties that engage his attention. Truth to say, he has practically made the garden what it is, and so closely does he feel the tie between it and himself, that instead of inviting his friends to inspect his garden, he attacks them with the formula, "Come away in and tell us how I'm looking"; while, should the visitor unduly delay giving expression to his opinion, he is quickly reminded by the query, "Weel, what d'ye think of me? My Carcases (Cactus Dahlias?) are no just the thing, and no doubt ye've seen finer grossers; but I was thinking I might ha' been waur!" As I had good reason to know that James was trusted by his master and mistress, what was my dismay to be consulted by him on so serious a question as the resignation of his many offices? No longer young, it was a question with him almost of existence, but he had worked himself into a condition of body and mind that rendered his life quite miserable. And what, think you, it was about? Simply that he believed his services were no longer acceptable. In one or two things his master had given him the impression that he was not pleased. He came less into the garden, and left him unnoticed, when formerly he was always consulting him about some little thing. Matters that hitherto would have passed unheeded now became confirmations, strong as proofs of holy writ, that his employer had grown tired of him. A talk over his troubles left him decided to do nothing hastily, and very soon he knew that all his fears were groundless. I moreover took occasion to throw out a feeler when next I met his master, with the result that the servant was declared an invaluable one, and, indeed, had come to be looked on more as a friend than a mere servant.

The super-sensitiveness of which the above is an instance is by no means rare among gardeners, and there is good reason for thinking it is at the bottom of much of the changeableness so sadly apparent in the character of many gardeners. I could multiply instances; I have felt in exactly the same way myself, and I have had men under me

who somehow had caught the idea that their services were no longer wanted, without any shadow of reason in fact. Sometimes, no doubt, employers have themselves to blame, and not so long ago I was pleased to be able to secure another situation for a thoroughly good man who found it intolerable to serve his then master; yet, when he resigned his situation, the employer was astonished that he was not pleased with his place, himself being absolutely satisfied with his gardener!

This brings us face to face with what may well be called the personal equation in gardening. Some employers make much of their gardeners; others pay little attention to them. A personal friend has told me so long a period as nine years had passed without his meeting or speaking to his employer. Many men would have accepted this as a hint to quit when no such thing was intended. It is, I confess, an extreme case, but it serves to emphasise what I want to impress on those who may think they are being treated coldly, that they may not make too much of a small matter.

Occasionally, too, the temperaments of employer and employed are so essentially at variance that, much as a master may value the gardener from a professional point of view, he does not take to him as a friend; but it will be as hard, and, I believe, also an uncommon case, if some of the family do not come into close relations with him. There is a class of employers, too, that treat all their servants with the greatest urbanity, while they are as yet new to the place and their duties, and who by-and-by subside into habits that what I may call thin-skinned people find it very hard to endure. The only antidote is to thicken one's epidermis, so that blow hot, blow cold, a conscientious fulfilling of duties is sufficient to throw off any condition of social atmosphere. It is unnecessary to enlarge on a subject so very extensive in its purview. Enough to say that the custom of making rods for one's own back out of nothing is one to be greatly deprecated, because it produces, perhaps, a more severe chastisement than real fault finding, and it has a tendency to lead to ruptures entirely of one's own production, and fatal to any little success in life it might be possible to secure.—TATLER.

### Tomatoes in Trenches.

The method of growing outdoor Tomatoes in trenches used to be practised by Mr. J. Forbes, when at Dover House, Roehampton, Middlesex. On a sheltered plot of ground, sharply sloping to the south, a trench was dug about 4ft wide, and strong Tomato plants were placed in suitable soil at the proper time in May. The trench was covered with open latticework, through which the plants grew, and were trained down to it, and fruits were thus obtained in abundance during the summer. We bring up the matter now, in order that a place may be marked out for a trial of this plan next spring.

Tomatoes in Trenches.

# NOTES & NOTICES

## Royal Appointments.

Messrs. William Bull and Sons, New Plant, Seed and Bulb Merchants, 536, King's Road, Chelsea, London, S.W., have been honoured with the appointment of Florists to His Majesty the King. \* \* Messrs. Dobbie and Co., Rethesay, Bute, and Orpington, Kent, have received a Warrant of Appointment as Seed Growers and Florists to the King. Messrs. Dobbie and Co. held a similar appointment to the late Queen Victoria.

## Journal Rose and Chrysanthemum Analyses.

Mr. Edward Mawley's Rose Analysis (1895-1902) is now in hand, and will appear in our issue for November 20, together with the portraits of some of the leading commercial Rose growers. \* \* In reference to the Chrysanthemum Analysis, which will be published very early in January, Mr. E. Molynaux wishes us to state that he will shortly be sending out his papers, and asks the experts to note well their favourites, in order that the audit may be strictly just and valuable.

## Mistletoe in Paris.

Last week the first Mistletoe made its appearance in the Paris streets. It is not sold from barrows, as at home, but the hawkers carry it in bunches slung upon poles from 6ft to 10ft long, and what they sell is not Oak Mistletoe at all, but Mistletoe from Apple trees.

Brittany, says the "Evening News," is the only one of the French provinces where the real Oak Mistletoe is found, and this is sent off to London by ship-loads from Granville and St. Malo, and obtains better prices than it would in Paris. Even our Christmas decorations, therefore, are made in France.

## Appointments.

Mr. W. Hammond, for the past two and a half years foreman in the fruit houses and kitchen garden at Ashton Court, has been appointed gardener to E. S. Goodsell, Esq., Caius Cross House, Stroud, Glos. \* \* Mr. Alex. McLean, gardener to Sir Wm. Clark, Curling Hall, Largs, N.B., has been appointed gardener for Earnock. \* \* Mr. John Tunnington, late head gardener to Sir H. Ingilby, Ripley Castle, Yorks., has been appointed head gardener to Col. Charlesworth, Fern, near Salisbury, and enters on his duties in a few days. \* \* Mr. Geo. Hawes, late head gardener to W. Grazebrook, Esq., Thenford House, Banbury, as head gardener to Mrs. Goodson, The Grange, Sutton Courtenay, Abingdon, Berks.

## Fruit Growers and Railway Rates.

That any part of England, more particularly such comparatively accessible counties as Hereford, Worcester, and Somerset, should under any circumstances be debarred, by prohibitory railway rates, from selling fruit profitably in English towns is indicative of a very regrettable state of affairs. It is not to be wondered at that the organisations formed to look after the interests of the fruit-growing industry should have resolved to make a move in the matter, for it is not creditable either to the industry or the railway companies that the present state of things should obtain. The fruit growers at the recent Worcester meeting resolved to press upon the railway companies the urgent need of improvement in the loading of fruit, the use of refrigerator cars, and closed but ventilated trucks, more prompt delivery from the terminus to the market, quicker return of empties, and clearer definition of owners' and railway companies' risks. This is a fairly heavy list of demands, although probably it does not in the least exceed the alterations required by the nature of the traffic. It is pretty certain, however, that if these requests are conceded the railway companies will require in return some kind of guarantee that the consignments will be prepared and regulated as to quantities in such a way as will enable them to perform their indispensable part expeditiously and cheaply. It is essentially a case of give and take, and if both parties approach it in this spirit a satisfactory settlement should be easily arranged.

## Incurved Chrysanthemum Charles H. Curtis.

For a number of years now this variety of sterling merit has been seen on exhibition boards at the Chrysanthemum shows. This week at the Royal Aquarium it formed one of the finest half-dozen incurved Chrysanthemums, having size, even build, globular form, firmness, smoothness, and rich colour (intense golden yellow) to commend it. A First Class Certificate was awarded for it some years ago. Growing about 5ft, and producing good blooms as a rule, it is one which every grower ought to have. A figure of it is given on page 431.

## Horticultural Show Schedules, &c.

We have received the following schedules and syllabuses: Advance prize schedule for the spring show (May 20 and 21) of the Royal Caledonian Horticultural Society. Secretary: P. Murray Thomson, 5, York Place, Edinburgh. Ipswich and East of England Horticultural Society. The Chrysanthemum show will be held on November 11 and 12. Secretary: H. E. Archer, 13, Museum Street, Ipswich. Birmingham and Midland Counties Gardeners' Mutual Improvement Association. Programme of lectures for autumn session. Secretary: W. L. Deedman, Hawthorn Road, Chad Valley, Edgbaston. Devon and Exeter Gardeners' Association, autumn session syllabus. Secretary: Andrew Hope, 38, Prospect Park, Exeter.

## The Pearson Herbarium.

The Department of Botany in the British Museum has acquired, says the "Yorkshire Daily Post," the extensive collection of British and exotic Hepaticæ, or Liverworts, formed by Mr. W. H. Pearson. The collection consists of over 9,000 specimens, and is mainly representative of British Hepaticæ; but it contains also valuable material from New South Wales, Tasmania, Canada, Madagascar, South Africa, and elsewhere. The scientific value and interest of the collection are much enhanced by the fact that Mr. Pearson's recent standard book on British Hepaticæ is based on the study of his specimens, which have become the property of the nation. Owing to the recent purchases of the Stephani and Bescherelle cabinets of exotic Liverworts, the Museum possesses an unrivalled series of Hepaticæ, the deficiencies in the British collection being now made good by the Pearson Herbarium.

## Canadian Fruit in Liverpool.

Since your paragraph appeared announcing the consignment of Canadian Apples, the Liverpool public have had a splendid opportunity of viewing some of the most beautiful specimens ever seen in Liverpool. Too many of our foreign Apples lack the weight so desirable, but with the appearance and weights of some of these choice Canadian fruits no fault could be found, as a Bietigheimer weighed one pound; King of Pippins over fifteen ounces; Fallawaters, fourteen ounces; and also some grand examples of Ribstons, Gloria Mundi, and Blenheim. They make an effective display arranged in baskets, and Mr. Thomas Dowd must consider himself honoured to have the care of this valuable collection, which had been sent direct from the exhibition at Kentville, King's County, Canada, by Sir F. Bowden and Mr. L. S. Eaton.—R. P. R.

## Isle of Wight Horticultural Association.

The monthly meeting of the above Association was held at Warburton's Hotel, Newport, on Saturday last, November 1, when Dr. Groves, B.A., J.P., presided over a good attendance of members to hear a paper on the "Cultivation of Cyclamens," read by Mr. A. J. Cole, of Sandown, who treated the subject in a very able manner, and supplemented his remarks by staging a mass of superb blooms of Cyclamen persicum. On the motion of the chairman, seconded by Mr. A. Kime, a hearty vote of thanks was accorded to the essayist. A most interesting and profitable discussion followed, in which Messrs. Sheath, Bennett, Collister, Brett, and several others took part. Mr. Collister was accorded the best thanks of the meeting for staging a lovely collection of Tea-scented Roses; also Mr. J. Lee, gardener to Dr. Riley, J.P., Bramble Chine, Freshwater, for a superb collection of unnamed seedling Zonal Pelargoniums, all his own raising, and in the opinion of some of the members equal to the best named varieties. Several new members were elected.

**Winter Strawberries.**

Wild Strawberries seem to be found in Devon and Cornwall nearly all the year round. No less than twenty-three ripe ones are reported to have been picked at St. Germans recently.

**October Weather in Bucks.**

The rainfall at Temple House Gardens, Great Marlow, Bucks, for October, 1901, was 1.79in. There were three foggy mornings during the month, viz., on the 19th, 24th, and 28th. The highest temperature for the month was 64 on the 10th, and the lowest 30 on the 18th. The highest for October, 1901, was 73 on the 1st, and the lowest 27 on the 26th. The rainfall for October, 1901, was 2.19in. We are situated close to the banks of the River Thames, and 105ft 9in above sea level.

**Apple, Rival.**

This already much-esteemed Apple was certificated in 1900, and is offered by Messrs. W. Clibran and Son, of Oldfield Nurseries, Altrincham, Cheshire, from whom a brightly coloured fruit was sent to us a week ago. Our figure of it on a back page gives a good impression of its appearance. It is a free grower, with an upright habit, and well adapted for orchard cultivation: the fruit has a very good flavour. It is a good cropper. Its exceptionally handsome appearance should insure for it a ready welcome for market purposes. The flesh is creamy white, soft in texture, and of good flavour. The colour is bright red, splashed with crimson on the sun side, and rich yellow on the shaded side. It is in use for dessert at this season and onwards. The parentage was Peasgood's Nonesuch x Cox's Orange Pippin.

**Vine Culture at Liverpool.**

The first lecture of the session was held in the secretary's offices, Victoria Street, on Saturday, the chair being occupied by Mr. T. Foster, chairman, who presided over a good attendance. The lecturer for the evening was Mr. J. Stoney, the esteemed head gardener to F. H. Gossage, Esq., Camp Hill, Woolton, who gave an admirable and thoroughly practical address on the cultivation of the Grape, his remarks being sound and of incalculable benefit, more especially to the younger generation of gardeners. Muscat of Alexandria and Madresfield Court have all along been specialties of Mr. Stoney, and few gardeners know their peculiarities better, as witnessed at the Liverpool exhibitions, where they played many important parts. The writer has in his mind's eye some splendid bunches of Madresfield Court grown in an outside border, the entire centre of the house being devoted to Camellias in pots, yet there was no lack of bloom on bunches and no cracked berries. This was at Allerton Towers, and now at Camp Hill the same progress can be written down. Coming from a practical man like Mr. Stoney, the lecture of Saturday last proved invaluable. The usual votes of thanks were passed.—R. P.

**Highgate and District Chrysanthemum Society.**

The following awards were made to the Trade Exhibits after the judging had finished last Wednesday, viz: Gold Medals to Messrs. W. Wells and Co., Limited, Earlswood Nurseries, for a group of Chrysanthemums. Miss Bevan, The Lodge, East End Road, East Finchley, for a dinner table with fruit, flowers, &c., with centres and d'oyleys in satin, with hand-painted Chrysanthemums in miniature, laid out for fourteen persons. Silver-Gilt Medals to Messrs. W. Cutbush and Son, Highgate, for a group of Carnations and flowering plants. Austin and Co., Kingston-on-Thames, for collection of bottled fruits. Williams and Son, Fortis Green, for collection of Primulas. Silver Medals to B. S. Williams and Son, Upper Holloway, for group of flowering and foliage plants. Cheal and Sons, Lowfield Nurseries, and J. Russell, Richmond, for collections of fruit. W. Wood and Son, Wood Green, for garden sundries. Pearce and Co., Upper Holloway, for greenhouses, &c. Bronze Medals to W. Colchester and Co., Ipswich, for exhibit of pure Ichthemio guano, &c. Mr. Williams (Hammersmith) and Mr. C. J. Wakefield, Hindon Street, London, for floral aid stands for cut flowers. Mr. J. H. Witty, Highgate, for collection of shrubs. The Floral Committee met in the afternoon, October 29, and First Class Certificates were awarded to the following varieties of Chrysanthemums: Lord Alverstone and Mrs. A. McKinley, both exhibited by W. Wells and Co.; Mrs. Mileham, exhibited by Mr. T. L. Turk.

**American Flower "Combine."**

A combination of firms representing a million dollars has been formed for the purpose of controlling the New York market for flowers.

**Giant Seed Potatoes.**

Mr. T. Kime, of Marcham-le-Fen, has bought a new variety of seed Potato, named the Northern Star, in Lincolnshire, at the record price of £500 per ton. Twenty-two pounds of this Potato produced 15cwt of tubers.

**Sussex Weather.**

The total rainfall at Abbot's Leigh, Hayward's Heath, for the past month was 2.07in, being 1.80in below the average. The heaviest fall was 0.46in on the 15th; rain fell on thirteen days. The maximum temperature was 65deg on the 10th, the minimum 32deg on the 19th. Mean maximum, 53.27deg; mean minimum, 41.18deg; mean temperature, 47.22deg, which is 1.33deg below the average. October has been with us, on the whole, a pleasant month, especially towards its close. There has been no frost to kill the Dahlias, and they are still bright with bloom. Roses have been, and are still, quite gay, and Violets, too, are quite plentiful and welcome for picking.—R. I.

**Walsall Gardeners' Association.**

The third fortnightly meeting of the autumn term of this comparatively new society was held at the Victoria Temperance Hotel on Tuesday night, October 28, with the popular chairman (a successful amateur orchidist) presiding. There was a good muster of the members. Mr. W. Gardiner, Harborne, Birmingham, delivered a lecture, entitled "A Chat about Conifers, with Illustrations of Cones." The latter were objects of marked interest to the audience, more especially such as specimens of the Monkey-puzzle (*Araucaria imbricata*) and coned branchlets of *Abies cephalonica*, *Pinus Jeffreyi*, and *P. Ayacahuite*, *P. insignis*, and *P. excelsa*; also Cedars Libani, Atlantica, and Deodara; also of *Wellingtonia gigantea*, and *Pseudotsuga* (*Abies*) *Douglasii*.

**Watering at Planting.**

Nurserymen are often asked if trees should be watered at planting. In ordinary spring planting, water is seldom necessary; but late in spring, when buds are pushing, and heat is increasing, watering often helps a tree to recover from the check of transplanting, especially should the soil be dry. In autumn, should the ground be dry, as it often is, watering is of much benefit. The dry soil can be got around the roots nicely, and a good watering compacts it. The moisture and heat combined cause new roots to form at once, at least, before cold weather. In a general way it may be said that a good watering at planting never hurts a tree, and is usually a great help to it. The continual watering all summer long, which amateurs so often indulge in, has killed more trees than it has saved. One watering is sufficient, unless a time of drought sets in, calling for the watering of all trees.

**Bristol Gardeners' Association.**

A most successful meeting of this society was held at St. John's Rooms, Redland, on Thursday evening last, when Mr. J. H. Jarvis, of the Newport Gardeners' Association, gave a most exhaustive lecture on the Cultivation of Pot Roses. Mr. E. H. Binfield occupied the chair, and there was a good attendance. The lecturer divided his lecture into sections, dealing with each in a very practical and masterly way, and it was quite evident the subject was in good hands. He fully described every detail required for the successful cultivation; the houses most suitable; soils and composts, pruning, and general treatment. Prizes for six cut Roses were awarded, the first going to Mr. J. C. Godwin (gardener, Mr. McCulloch); Mr. A. Baker (gardener, Mr. Orchard) obtaining second. Certificates of Merit were awarded to Mr. Ross for six dishes of Pears; Mr. Gilbert Howes (gardener, Mr. White) for *Dendrobium chrysanthum*; Mr. W. Howell Davis (gardener, Mr. Curtis) for *Cattleya labiata*; Lady Cave (gardener, Mr. Poole) for cut specimens of Bamboos, and to Col. Goss (gardener, Mr. Shaddick) for a dish of open-air Tomatoes and a well-grown Croton. The next meeting will be held on November 13, when Mr. E. H. Binfield will give a lecture on stove and greenhouse Ferns.—H. K.

## Hardy Romuleas.

It seems unfortunate that so few of the Romuleas are obtainable in the ordinary course of trade from the bulb dealers. There are among them some lovely little flowers, and it is probable that all, or almost all, of the species belonging to the Mediterranean region would prove hardy in dry, sunny places in light soil with plenty of shelter from cold winds, as may be had in almost any rock garden. Of the twelve species belonging to this region, recognised as such by Mr. J. G. Baker, there are very few procurable by purchase, and one or two of those which are not quoted by the dealers would appear to be among the most desirable of the genus. In the following brief notice of these flowers I have purposely excluded the species from the Cape and tropical Africa, as hardly likely to be hardy in the open in our climate. It may be mentioned now that these plants are often to be found under the names of *Trichonema*, and that Mr. Baker classes them, in his arrangement of the Irideæ, in the tribe *Sisyrinchieæ*, and the sub-tribe *Croceæ*, which comprises the *Crocus*, the *Syringodea*, *Galaxia*, and *Romulea*. This will give a general idea of the character of the Romuleas, which are small *Crocus*-like flowers with narrow, grass-like leaves, and opening out only in the sun. This last point certainly limits their usefulness, but they are attractive enough when open to repay one for the shortness of the display in any one day. The flowers show well beside the leaves at their flowering time, and make a pleasing, if quiet, effect. I like to plant about 2 in deep, and to give a covering of cocoa fibre for the first winter, allowing this to decay naturally. This helps to protect the small *Crocus*-like corms. I have planted at various seasons, either when in full growth, when at rest in autumn, or, with late received corms, have kept them until early spring in a dry state.

The *Romulea* most easily obtainable is neither so scarce nor so expensive as the others, and may be planted in some quantity at a very small cost. This is *R. Bulbocodium*, a widely-spread species in the Mediterranean region, which has had at various times the names of *Ixia Bulbocodium*, *Trichonema Bulbocodium*, *T. collinum*, and *Romulea uliginosa*. It has pretty lilac flowers with a long yellow throat. It has given rise to a number of varieties, several of which are hardly distinguishable from the type, and others are not apparently obtainable. *Grandiflora*, *rosea*, *pulchella*, and *syrtica* belong to the former category, and are sometimes to be found in Continental catalogues; while *flaveola*, yellowish white; *subpalustre*, white near the base and lilac above; *umbellata*, deep lilac on short peduncles; *crocea* and *nivale*, both with yellow flowers tinged with lilac, may be classed with the unobtainable ones. *T. B. pylum*, frequently sold as *T. pylum*, is, however, in commerce, and is one of the prettiest of the Romuleas, with large white flowers with a yellow throat.

*R. Clusiana*, or *Clusi*, which has long, yellow flowers tipped with lilac, comes from Spain, and is also in cultivation. The white variety of this is still rare. *R. Columnæ* is also in cultivation, and is desirable, though less so, in my opinion, than some. It comes from various habitats, said to range from the Azores and England and Portugal to Greece. This species has a short yellow tube, and has pale lilac segments veined with purple. *Modesta* and *sub-albida* are said to be allied forms. *R. rami-flora*, with narrow lilac segments and a yellow throat, is also procurable.

I have had *R. Linaresi* from the south of Europe. It has its flowers of a bright lilac down to the base. *Elongata*, *grandiscapa*, *ligustica*, *Requieni*, and *Relievieri* ought all to be hardy with us; while the fine *crocifolia*, a Dalmatian species with large bright yellow flowers, ought to be introduced if possible. *Numidica* is doubtfully hardy, I believe, and its Algerian habitat is not very encouraging for a trial in our climate. These little flowers come in very acceptably at a time when such unobtrusive blossoms are welcome, varying in date from March to July, few blooms, however, appearing at the earliest period named. With a little extra care for the first winter or two, they will give much satisfaction for those who are admirers of the smaller flowers with bulbous roots. I have to express my indebtedness to Mr. Baker's invaluable "Handbook of the Irideæ" for much information.—S. ARNOTT.

### Cedar Wood.

The resistance of Cedar wood to decay has long been famous, and Cedar fence-posts often last for generations. A remarkable instance of the indestructibility of Cedar has been noted in the State of Washington, where a forest of Hemlocks, near Acme, has grown up over an ancient buried forest of Cedars. The trunks of Cedar, although lying in a moist soil, have been almost perfectly preserved for at least 150 years, the length of time that the rings of growth show the Hemlocks to have been growing above their fallen predecessors.

## Pruning Fruit Trees at Planting.

There are few gardening operations in which there is a greater diversity of practice than in this. The ordinary amateur, who hears one opinion from his nurseryman, another from his gardener, and finds something different to that of both in some fruit manual or cultural notes, may well feel puzzled as to which is the best course to pursue. Let us hear what two or three authorities say, and see how much they differ. A Kentish firm of great renown, and well represented at the last Crystal Palace Fruit Show, says: "Prune fruit trees, immediately on arrival of trees, whether standards or dwarfs, as per cross-cuts shown on the enclosed engraving (one-half to two-thirds of their length), and if you err at all, let it be that you shorten their shoots even more than shown." One of the largest raisers of fruit trees in England, if not the largest, says: "Plums, Peaches, and Nectarines may be pruned back the first year of planting in April; and, if planted early, Apples, Cherries, Apricots, and Pears, as garden trees, may be treated in the same way, but they generally succeed better if allowed to grow for a season without pruning."

In an essay, which secured the gold medal from the Worshipful Company of Fruiterers, the author advocates the pruning of trees in the spring following planting. The Royal Horticultural Society, in their excellent pamphlet on fruits for cottagers, says: "In order to promote good strong growth, standard Apples, Pears, and Plums should have their shoots shortened at planting to about one-third of their length, and young bush trees should be treated in the same way as standards." Here is a conflicting mass of advice! Each one of those quoted above is presumably prepared to back up his advice by experience, and could make out a good case for it. Doubtless, all these methods answer well in skilled hands, though some better than others. One is reminded of the lines in the once famous, but now little read, classic:—

'Tis with our judgments as our watches, none  
Go just alike, yet each believes his own.

I have adopted one uniform practice for some years past, and do not intend changing it, as experience shows it to be so satisfactory with my soil and situation: but, with such a weight of authority as quoted above, it would be presumption on my part to speak dogmatically in favour of any one system, but it may be profitable to look into the various methods, the scientific basis upon which they rest, and the way they actually work in practice. A knowledge of general principles underlying diverse practices is often more helpful than a knowledge of such practices themselves.

If we were to carefully examine the earth from which a young fruit tree has just been taken up we should find it full of pieces of root-fibre. Each one of these formerly helped to nourish the tree, and therefore the tree has as much less power to feed itself in its new home, before it gets established, as is represented by the loss of all these root-fibres. If the tree still has the same amount of branch to maintain, it is obvious that it can have but very little energy left for adding to its liabilities by making fresh shoots the first year, and the probability is that most of the buds which should have formed shoots will form blossom-buds for the following season, while many of the buds on the lower parts of the stems will not break out at all. The season following the tree will probably bear fruit, but the branches, being no thicker than when the tree was planted, will bear down to breaking with even the weight of a small quantity of fruit, and the shape of the tree will be spoilt for the future. This is universally agreed upon by experienced men, and, therefore, those who advocate leaving the trees untouched for twelve months also advocate the cutting back, at the end of that time, not only of any young growth that may have been made the first season, but of a large part of that of the season before—their last season in the nursery—so that when you have had the tree a year and a half it is much smaller than when it was planted; but from these shortened branches of two-year-old wood very strong growths will burst out the following spring, and thus what is lost in the size of the tree is gained in vigour.

There is undoubtedly a good deal to be said in favour of this system for standard trees, where the first object is to get a strong healthy tree, able to bear the weight of fruit before a crop checks and enfeebles the growth. It is doubtful, however, if any better results are obtained this way, even with standards, than is obtained by cutting back the branches to half their length at the time of planting—always supposing this to be done before Christmas—when two good strong shoots will grow from each cut-back branch, while on the lower part of it fruit spurs will form; and then, by cutting off not more than a quarter of these young shoots in the autumn fruit spurs are formed upon them and strong growth maintained, and thus the branches become well feathered with fruit-spurs—a very desirable object gained. Thus we see the working of this general principle—cutting back a newly-planted tree induces vigour of growth, leaving them unpruned leads to fruitfulness (and, probably, unsightly, naked branches) even before the tree is strong enough to support it.

When we come to bushes, pyramids, and dwarf trees generally,

the case is very different. We see that deferring the cutting back of the trees till after a season's growth adds to their vigour of growth.

But do we want to encourage this vigour in dwarf trees? Is it not a fact that excessive vigour is an evil we generally have to fight against in young dwarf trees until a heavy crop of fruit has brought about a well-balanced growth? Surely, the object is to get dwarf trees to bear early, so that excessive vigour may be restrained and the necessity for lifting and root-pruning obviated, as this usually means the loss of a season's fruiting. By the system of cutting back at the time of planting, as suggested above for standards, fruit spurs are formed all along the branches—a sine qua non for a really productive dwarf tree—and it does not harm it at all to bear fruit the second season, as the formation of a strong tree is not of prime importance in such cases, though this is pretty sure to come.

The pruning of dwarf trees must to some extent depend upon the object for which they are grown. If they are planted by the acre, where a small early return is not wanted so much as an ultimate large one, the trees are allowed to grow much bigger, and, consequently, the same thing may apply to them in that case as was mentioned above in regard to standards, namely, that by leaving the pruning till a year or eighteen months after planting, stronger growing trees are ultimately obtained, though pretty nearly as strong growth may be obtained by cutting back harder at the time of planting and disbudding in the spring, so as not to get too many branches formed, but just as many as required, and those strong and vigorous; but when trees are planted by the acre they can seldom get this delicacy of attention, and hence the deferred pruning may answer best in such cases.

As a rule, in gardens the bushes are not wanted very large, and the space is not allowed them to become so, and a small early return is usually desired, if only that of a dozen fruits on the tree. Where Apple growing, or that of some other fruit, is a sort of hobby, the desire, of course, generally is to get a considerable number of varieties, and to get them to fruit as soon as possible. In such cases, and with the amateur generally, the balance seems to be in favour of cutting back the branches to a third of their length at the time of planting. There is one thing which cannot be too strongly insisted upon, and that is, that any system of pruning to be successful must be combined with a knowledge of the sorts operated upon. Different varieties of the same fruit have as different constitutions as human beings, and what may be quite right for weak growing Apples, for instance, like Scarlet Nonpareil or Mannington's Pearmain, may be quite wrong for rampant growers like Bramley's Seedling or Blenheim Orange. Pruning should aim at increasing the vigour of the former two and decreasing that of the latter two.

The above has been an attempt to show the general principles upon which the pruning of fruit trees at planting, or a year after, is based, and though nothing is said dogmatically as to the rightness or wrongness of either system, it may be helpful to the reader, upon whom the foregoing dissertation may not have left a very clear impression, to give an account of one's own practice and experience as applied to the different sorts of fruit trees—to descend from the general to the particular, in short.

Apples, Pears, Plums, Cherries, and Apricot standards have all their branches cut back at the time of planting to one-half or a third of their length, weak-growing varieties being cut back harder than strong-growing ones. Bushes, pyramids, and wail trees—all forms of dwarf trees, in fact—are cut back to two-thirds to three-quarters of their length, according to the strength of the shoots or branches. In the spring the growth of the standards is regulated somewhat by any misplaced shoots, or any for which there will not be room being removed completely. In the case of dwarfs such shoots are usually pinched back to four or five leaves, and the secondary growths to one or two, though, at the same time, any very badly placed shoots are removed. Disbudding, as this is termed, is very helpful in forming young trees, and it is better for the tree for tender young shoots to be just rubbed off than to be cut off later on. Especially is this the case with stone fruit trees.

Peaches, Nectarines, Gooseberries, and Black Currants. These being all berries on the young wood, the stronger the growth that can be developed within certain limits the better. Therefore, these are cut back hard at the time of planting, strong shoots to two-thirds of their length, and weak ones to one-third. Disbudding with Peaches and Nectarines is, of course, a necessity.

Raspberries are shortened to six or eight inches the end of March or beginning of April. If shortened in the autumn the canes frequently die down further, which is supposed to be caused by the moisture getting into their pithy stems and there freezing.

Trees which are subjected to the treatment just described are invariably planted as early in November as possible. With late or spring-planted trees it is probably best to defer all pruning till after a season's growth. Pruning trees late in the winter or early in the spring makes the trees later coming into leaf, with the result that less root power is developed during the

summer, and, consequently, the growth is very feeble. It weakens the trees, too, in another way, in that, during February or March, the slowly rising sap is most of it going to the buds near the ends of the branches—whence the strongest shoots usually issue—with the result that the summer growth is made from the weaker buds. This is remedied, at least, to a great extent, when the branches are shortened in November.

There is one very important matter which has not been mentioned, and that is, never let the roots of trees get dry before planting, as the delicate root fibres are very easily killed, much to the injury of the tree. If the trees have to be a long time out of the ground before planting, from wet, frost, or other causes, it is a good plan to immerse the trees—roots and branches alike—in a tub of water for twenty-four hours, which will ensure all being plump when planted.—A. PETTS.

## Puzzles—Horticultural.

Potatoes are puzzling things to the average mind, and are interesting as well as useful, because they are so erratic. One never knows what to expect from them at digging time, because the appearance of their tops indicate but little how things have fared below the soil. These matters have been brought forcibly to my mind recently at a social gathering "in the country." After supper out came the pipes, and for a time silence reigned as each contemplated the wreaths of rising smoke. At last the stillness was broken, the topic of the speaker being a genuine one—in the country—'twas about gardening. I should here mention that each of us possessed a bit of a garden, and after having for a few years spent what time we could spare in practising the ancient art according to our own notions, each seemed to look upon himself as quite an authority on the subject. But the Potatoes have certainly been too much for some of us this year, which the following remarks will show.

"Potatoes," said one, "why, my early ones were the worst crop I ever had. The tops turned yellow before they appeared to be fully grown, the tubers were small, and what few I could spare for table after having saved enough for seed, were scarcely worth eating, and yet they were my favourite sort, Puritan." "Ah!" chimed in another, "I am in a far worse plight than you, for my late sorts have produced nothing to speak of except tops. They looked splendid during the summer, grew very strong, and were perfectly healthy, but when I tried a root or two I found only a very few tubers about the size of walnuts. I offered my neighbour the whole six rows for the trouble of digging, and he thought it wouldn't be worth his while." Very much I should like to know why Potatoes behave thus when fairly good treatment is given them.

It seems, too, that appearances are sometimes deceptive in the opposite direction, according to what a third member of our little band told us. Said he: "I wanted to grow a few tubers for show, and, among others, I planted Ideal. When they came up the tops were almost as weak as knitting needles, and although they improved by degrees, the haulms were always weak, thin, and wiry. Guess my surprise, then, when, at digging time, I found beautiful shapely tubers of good size, and managed to beat all the rest of you at the show!" Is this the usual behaviour of Ideal? How much I should like to know.

### CANKERED APPLE TREES

have often set me ruminating, and even now I do not understand their ways, because those who ought to know tell me that canker is a fell disease hard to eradicate, and, if left alone, disastrous to the trees. Now, I know of several trees which have eruptions studding their trunks and branches so closely that it is difficult to find a smooth bit of bark; such trees, I am told, have canker badly, and yet nearly every year they seem to bear well, while healthy trees growing near are fruitless. The fruits on the former trees are certainly not very large, but still they colour well, and although the trees must be old they are only of moderate size—the canker seems to have stunted them and made them bare. Is canker, then, after all, such a troublesome disease, seeing that it brings money to the pockets of some growers? Please tell me, someone, through the pages of the *Journal of Horticulture*. I should think that if those who have cankered trees would feed them well, and water with liquid manure, so as to increase the size of the fruit, there would not be much to complain of.

Talking, or, rather, writing, of liquid manure, reminds me of another point I have an idea about. Some time ago I saw a man watering an Apple tree in an orchard. The fruits were numerous, but small. He thought a little liquid manure would help to increase their size. I also should think it ought to, but it did not in this case. The tree was a large one, with a hollow space around the trunk; all the liquid was poured there. I thought the man should have watered a good distance from the stem as well, because, when digging under my Apple tree, I find the most roots a long way from the stem. Will someone kindly enlighten me on some of the above points, so that, in regard to them, I may no longer remain an—IGNORAMUS.

CHRYSANTHEMUM, C. H. CURTIS. (See page 427.)

### National Chrysanthemum Society's Show Judges.

I have just been looking through the schedules of prizes of the National Chrysanthemum Society for 1902, and I find that five members of the Executive Committee are the paid judges at the exhibitions of the society, and of this number three of them are the principal officers of the society—men who, as members of the Show Committee, are supposed to be intimate with the names of the exhibitors and the classes in which they exhibit; and as members of the Show Committee they, I imagine, have the direction of the placing of the various exhibits. More than this, I also perceive that the three principal officers who are judges are also members of the Arbitration Committee, whose duty it is to deal with any protest as to the awards of the judges; so they may have to consider protests made in reference to their own awards. By referring to the schedule of prizes for 1901, I find that eight members of the committee were judges in that year, so that there is reason to hope that the proper but unsuccessful attempt made at the last general meeting to so alter the rule of the society as to the election of judges so as to disqualify members of the committee from acting in that capacity—an alteration which the "Gardener's Chronicle" stated to be both just and proper—has had some good effect, as seen in the reduction of the number of judges in the present year taken from the committee.

The practice of selecting to make awards those who administer the affairs of the Society is opposed to universal practice, and so liable to be adversely criticised that I am astonished so influential a society, which I have heard claims to be the foremost special floricultural society in the kingdom, sets such a bad example to its many affiliated societies. If the whole of the men capable of judging Chrysanthemums, &c., are included in the committee, there would be some excuse for what is little better than a scandal. So far from this, there are about the country many men who, in addition to possessing the highest qualifications as judges, are also warm supporters of the society; but these receive no invitation, though in not a few cases their services are in demand as judges elsewhere.

If anyone will turn to the back page of the third leaf of the schedule of prizes, they will see set forth the composition of the Schedule Revision Sub-Committee, who have the nomination of the judges; four of the members of that committee are judges, and so nominate themselves. If any six members of that committee will agree among themselves to nominate and vote for each other and no other candidate, taking care to be present at the meeting when the nominations are made they are certain to be elected, as I am informed that the Executive Committee who make the final selection, invariably accept these self-made nominations. It is a scandal which is operating to discredit the society in the provinces. The sooner the members remove it the better for the society, which, just now that it has to seek a new home, needs all the support it can obtain.—A COUNTRY MEMBER.

### Floriferous Lapagerias.

I was much interested to read in the *Journal of Horticulture* of October 25, page 378, of the very fine specimen of *Lapageria* growing under the care of Mr. Powell in the gardens of Colonel Brymer near to Dorchester, and when seen as described they are a gorgeous sight to look upon. There is no other greenhouse plant as a climber that I am acquainted with that furnishes the roof with such a profusion of flowers, and yet one so seldom meets with *Lapagerias* under flourishing conditions. In the gardens here the plants grow with the utmost freedom each season, putting up their Asparagus-like shoots from the base of the plants, and growing some 15ft to 20ft in length in a season. I shall be interested, Mr. Editor, to know the number of blooms recorded on a single shoot from plants in other gardens. I am sending you a few sprays of ours for your inspection. You will see that No. 1 has thirty-four blooms, No. 2 has twenty-seven, No. 3 has fifty (one flower having been broken off), and last year fifty-one was our highest number on one shoot. The highest number of flowers is on a plant in a 10in pot, of *L. rosca albiflora*, there being thirty-two on a spray. Permit me to compliment Mr. Powell on his successful cultivation. I fully realise the amount of pleasure and satisfaction he, and also Colonel Brymer, must feel in looking on a well-cultivated and profuse flowering plant.—BENJAMIN CROMWELL, Cleveley Gardens, Allerton, Liverpool.

[Mr. Cromwell's heart would have warmed had he been able to observe the ecstasies of members of our office staff on our displaying the magnificent garlands of this exquisitely beautiful

climbing plant, on their receipt. Finer growths we have probably never seen, and, on counting the flowers, find that the numbers are as stated in our correspondent's letter. It would certainly be interesting to learn, through these pages, of the existence of other well-grown and floriferous *Lapagerias*, and the numbers of their flowers. Mr. Cromwell enclosed a handsome seedling, raised from two of his best forms. We make no reserve in saying that it is a decided improvement on the specific form, being more richly coloured, and both larger and heavier. It is well worth being attended to. This half-hardy Liliaceous twiner is a native of Patagonia, South America, and its coriaceous leaves, wiry stems, and fleshy flowers are typical of desert or dry land floras. The generic name was accorded in honour of Josephine Lapagerie, the first wife of Napoleon Bonaparte.—ED.]

### Red Spider and XL All.

After reading the very flattering remarks by my friend Mr. Easter on page 363, I feel, Mr. Editor, that I ought to give your readers an account of some experiments made some years ago, but related only to a few friends. It was in early autumn that I took charge of some vinceries and Peach houses, very badly infested with mealy bug and red spider, and my new employer told me they must be got clean. XL All was but little known at that time, so some of it was procured, and the early vinery was the first house to operate on, the foliage being just on the turn. The house was covered as far as possible with shading, and then the hose-pipe put on to thoroughly wet the top to make it stick and keep it as airtight as possible. About six o'clock the lamps were started, and fully one-half more compound used than the directions stated on the bottle, and the same dose at nine o'clock the same evening was given. In the morning we were surprised to find bug dead on the stages and floor. That night we repeated the two doses as before, the covering being left on for two days, while the hose-pipe was used to dislodge (?) as much as possible. I should have said that the second evening it rained all the afternoon and night, and on entering to trim lamps, &c., just before nine, the house was very full of vapour, and since then have found a wet night much more effective. The leaves on two Muscats were burnt very much, the others hardly touched; but no damage was really done to the canes, as they started next spring as usual.

By constant attention the bug was got rid of the same season, and by the time the fruit was ripe and cut red spider had not made any appearance. Peach houses were treated in the same manner when the leaves began to change colour, with the same good results. Orchids I always gave a second vapourising the same evening at the normal strength, without any damage being done. I advise keeping the blinds down the day after, using in all cases small fumigators, to have the vapour spread evenly over the house, and be careful to clean and scrape the bowls with a knife, so that no black sediment remains at bottom or sides, or much damage may soon be done. Vapourising every nine or ten days will do much to keep woodlice, ants, beetles, &c., in check, especially in spring, their breeding season. I see no reason why Mushroom houses should not be cleared in the same manner. I might add that we have never used any other compound but the one named, but feel sure that there are others good in the market, and just as effective as Mr. Kippis stated in his note on scab, which I was pleased to read. In conclusion, sir, I have a fancy for vapourising at six and nine, on account of having been told that a lot of insects come out to feed every three hours, namely, three, six, nine, and twelve; but there I must leave that point for some more able pen to explain.—T. T., Wakefield.

### Autumn Foliage in the Highlands.

Whatever season of the year the Highlands are visited, there is ample to exercise the imagination and interest the mind of the student of Nature. The dead of winter in those northern latitudes bespeaks its charms as forcibly as the genial warmth and sunshine of midsummer. The awe-inspiring mountains whose summits are lost in the clouds, robed in a mantle of several feet of snow, to the true artist and admirer of Nature is a sight no less worthy of his admiration than the blue and purple mountains clad in their summer vestments of Heath blossom. But, perhaps, at no period of the year does the face of Nature in any country call for general admiration so much as in the autumn, when the foliage is maturing from the trees, and nowhere in the whole kingdom could the changing tints be more full of splendour than they were a week ago in the greater part of the course of the Highland railway from Dunkirk to Daviot, near Inverness, and in the Highlands generally. In the vicinity of Carrbridge, Aviemore, &c., the white Birches, and Mountain Ash, Poplars, and the noble Scottish Pine combined to form a picture in the landscape difficult to rival in any country. The Birches, which are

abundant, were in all shades from green to a primrose-yellow; the Mountain Ash, deep red, Poplars an Italian-yellow, and all interspersed with the ultra-marine green (a shade to be seen nowhere but in the Highlands) of the young plantations of Scottish Pine. Around the seat of the chief of the Mackintosh, the scene was deeply intensified with the large sheet of water Loch Moy, on whose banks the historic residence Moy Hall stands. The Mountain Ash seem as the altitude increases to also increase in intensity of colour. In the vicinity of Kingussie and Kineraig the foliage was practically scarlet. For several miles on either side of the summit (which is 1484ft) trees of all kinds disappear, but on several occasions the roots of a primeval forest were seen exposed in the railway cuttings through the peat moss. These appeared to have been either cut or overcome by some disaster other than a gale, for the large roots sat in their original position, several feet below the present surface. Were they denuded by the influence of the moving icebergs of the ice age? The grass of Killierankie, perhaps, was among the finest of any of the scenes, for its grandeur of autumn foliage. Here the Oaks, Beeches, and Birches were exceedingly rich in tints. Oaks and Beeches were red, a tint seldom acquired in lower altitudes, and at Pitlochry the Oak coppice were almost scarlet, while the Spanish Chestnuts in the Dunkeld district were of a deep yellow hue. But alas! on leaving these higher altitudes and coming to the lower grounds between Perth and Glasgow, the general effect of woodland tints were dispiriting and gloomy. The trees were shedding their garbs in an apparent half-ripened condition, and those yet struggling for existence to the branches persisted in a dirty sickly green so unlike those we had been accustomed to see for the previous ten days.—D. C.

### Natural Reproduction of the Scottish Pine.

In a recent visit to the Beaully district of the North Highlands, my curiosity was very much attracted by a plantation of self-sown Scot's Firs. About thirty years ago this piece of land was a heath waste, on which a single seedling of Fir could not be seen, and now it is mostly covered with a plantation of singularly vigorous trees, rather above the average height and girth for that age. No one now living in the locality ever remembers of hearing of the place being at any time before under wood, and certainly there remains no signs in the soil, for several feet deep, of such being the case. "How did the Pines get there?" was the question I asked of an intelligent man of eighty-five years of age. "The woods at either end of the plantation are too far away for the seeds to blow over the whole area," I said to the man. "Well," said he, "as late as thirty years ago the Fir wood yonder contained a rather extensive rookery, and I remember how the rooks used to flock together in large numbers on this moor. At the time all the people supposed them to be feeding on stolen Potatoes from the crofters' allotments, but they probably were feeding on the seeds of the Fir cones taken hence from the wood, or, if not feeding on them, perhaps obeying one of Nature's great laws in helping to plant the seeds of the Pine."

"But allowing that either or both of these ideas are correct," said I, "how can you account for the regularity in which they sowed the seed, as the results now show?" My friend explained this by saying that the rooks did not confine themselves to one particular spot, but, on the contrary, were to be seen from time to time all over the heath. Some parts of this heath are exposed to the droughts of a summer's heat, and, though the soil conditions are not different, yet no Pines have grown at all on these parts; but where the Heather was long and the soil inclined to be seddened, the trees have grown with the vigour of Osiers. This would point to a very important fact in the artificial planting of Firs, namely, that moisture at an early stage of growth is not an undesirable thing for the successful growth of the Pine. The altitude of this self-sown plantation is not over 250ft above sea level, and the exposure is to the north.

I observed another instance, a few miles distant from this one, where the process of reproduction has been keeping pace with the axe of the woodman. The wood was planted after the last rebellion by the "Confiscated Estates Commissioners;" it would, therefore, be well over 100 years old thirty years ago, which age the rising forest appeared to be. Both these cases have given rise to a strong presumption in my mind that there is very probably a definite period in the age of the Pine when its seeds are better adapted for successful reproduction than at any other time, at least, that they are better able to overcome the hardships attending nature sowing. This period, I fancy, exists somewhere between the ages of eighty or 100 years. The altitude of this last wood is not over 200ft above sea level. It would be interesting to know from your sylvicultural readers what is the highest altitude at the present day that natural reproduction is taking place. I have an idea that our land has risen considerably since this process was universal in the higher mountains of Scotland, and that, therefore, it must be useless to expect Firs to grow again in many of the situations they flourished in the days of antiquity.—C.

## Societies.

### Royal Horticultural—Drill Hall, November 4.

Orchids and winter-flowering Begonias were prominent at Tuesday's meeting, while Messrs. Bull and J. Russell had nice grouplets of foliage plants; evergreens came from J. Waterer and Sons of Bagshot; and Chrysanthemums from Wells and Co., and Mr. Foster. Apples, too, were largely shown by Mr. Divers, and the Horticultural College, Swanley.

Hardy flowers were shown by Messrs. Barr and Sons, King Street, Covent Garden, who had Crocuses and autumn flowering Chrysanthemums chiefly; Messrs. Peed and Son, of West Norwood, brought Cattleyas and Cypripediums, together with Begonias Moonlight and Gloire de Lorraine var., Mrs. L. de Rothschild, the latter light pink, the former pale white. Mr. John Russell of Richmond contributed a group of exotic foliage plants, all of them exceedingly well grown. F. D. Lambert, Esq. (gardener, Mr. J. Fulford), Moor Hall, Cookham, contributed a creditably grown group of Turnford Hall Begonia.

Besides a group of Chrysanthemums in pots, Messrs. Wells and Co. staged cut blooms of Mrs. T. W. Pockett (a whole row of it), S. T. Wright, the new "gun"; W. R. Church, Mme. Herrewége, Matthew Smith, and a number of good unnamed seedlings.

Messrs. Harrison and Sons, Leicester, had an exhibit of Onions, including White Spanish, Harrison's Leicester Keeping, Rousham Park Hero, Nuneham Park, Banbury Cross, Bedfordshire Champion, Ailsa Craig, Excelsior, and Up-to-Date amongst others. The bulbs were fine, ripe, and of medium size, suitable for market and general purposes.

C. B. Gabriel, Esq., Easdale, Horsell, Woking (gardener, Mr. Calville), staged, in very good form, large bouquets of Zonal Pelargonium blooms. Amongst these were Mrs. G. Luizet, The Sirdar, Lady Curzon, Mark Twain, Mrs. Simpson, Lord Curzon, Mary Pelton, Herrick, Mary Beton, and Cerise, as the most telling.

Lady Warwick Hostel, Reading, sent bottled fruits.

Messrs. James Veitch and Sons, Limited, Chelsea, presented a gorgeous display of winter flowering Begonias, which occupied a table running almost the length of the Hall. Mrs. Heale was most conspicuous. Success, Julius, Ideala were also noteworthy, the table being edged with small Maidenhair Ferns; while Palms formed a good background.

Mr. James Hudson, gardener to Leopold de Rothschild, Esq., Gunnersbury House, arranged a few vases of Cactus Dahlias, which were undoubtedly good for such a late period.

Mr. H. B. May, Dyson's Lane Nursery, Upper Edmonton, contributed a seasonable display of winter flowering Carnations, which included Elma, America, Snowflake, Triumphans, Prince of Wales, and Resplendent, all of them tastefully displayed in masses of Ferns, Palms, Isclemis, and beautiful plants of Ficus repens variegata.

From Messrs. W. Bull and Sons, King's Road, Chelsea, came a choice exhibit of stove plants, in which Aglaonema costata, Nephthytis picturata, Dracaena Victoria, and Ceropegia Woodii were most conspicuous.

A creditable exhibit of Japanese Chrysanthemums was staged by Mr. P. R. Dunn, Caisteal Quath, Brockley Park, Forest Hill, all tastefully resting in a groundwork of Asparagus and Carex. Some of the best flowers were Mrs. Greenfield, Miss Hetty Dean, W. H. Webb, May Neville, Miss E. Fulton, Mrs. G. Mileham, Geo. Lawrence, and Master C. Seymour.

Mr. Robert Foster, Nunhead Cemetery, exhibited a large semicircular group of Chrysanthemums, beautifully arranged with Ferns and other foliage. The exhibit included all sections, the Japanese, Anemones, and pompons being most conspicuous, while a few cut blooms were arranged round the front of the group.

Messrs. John Waterer and Sons (Limited), Bagshot, Surrey, arranged a number of coniferous plants and Hollies on the floor in the centre of the hall; each were perfect specimens, clean and bright. The Hollies were well berried. Some of the best were Sciadopitys verticillata, Retinespora pisifera aurea, R. obtusa alba, R. plumosa argentea, and Thuja occidentalis aurca.

Messrs. Sutton and Sons, Reading, exhibited a good bundle of Rhubarb, "The Sutton," of good colour, grown in the open air without protection.

Amongst those showing Orchids were Messrs. Charlesworth and Co., Heaton, Bradford, with well flowered pieces of Sophro-Cattleya Nydia, Cattleya Portia, L.-c. Ingrani, L.-c. La France, Cattleya Mrs. J. W. Whiteley, C. Iris, Cypripedium insigne Sanderæ, &c. Sir Trevor Lawrence, Bart., staged a Cattleya labiata spray, with four huge flowers, and received a cultural commendation.

Messrs. James Veitch and Sons, Limited, staged a very bright exhibit of Orchids, including Cattleya Portia, five flowers per sheath; C. Mrs. J. W. Whiteley (four flowers); C. Ella; L.-c.

*Dominiana Langleyensis* L.-c. Bryan, L.-c. Gotteiana, C. Mantini, and some fine *Cypripediums*.

Captain Holford, C.I.E. (grower, Mr. Alexander), from Westonbirt, Tetbury, brought two splendidly flowered *Vanda Kimballiana*, *C. labiata*, with five strong flowers on a sheath, *Vanda Sanderiana*, *Dendrobium Phalaenopsis Holeleucum*, *D. formosum giganteum*, and *C. Ariel*, all of them exceedingly well grown.

J. Bradshaw, Esq. (gardener, Mr. G. G. Whitelegg), The Grange, Southgate, N., was forward with *Cattleya labiata*, and hybrids and varieties of it. *C. aurea* was very well shown. *C. labiata* Pride of Southgate was very fine. Sir F. Wigan, Bart., sent *Pleione Walliehi*, with a mass of flowers; *Odontoglossum spectabile*, with eleven flowers; *Cymbidium Traayanum*, with seventeen flowers, and other well grown Orchids in variety.

From Hugh Low and Co., Bush Hill Park, Middlesex, came *Cypripedium insigne Sanderæ*, *Cattleya labiata Amesiana*, with four soft white flowers, very beautiful; and splendid pieces of *Oncidium varicosum*. J. Gurney Fowler, Esq., Glebelands, South Woodford, sent *Dendrobiums* and *Cattleyas*, making a mass of flower; while from Messrs. Sander and Sons, of St. Albans, a group of the rarer hybrids was sent. They had *Cypripedium Coronis*, with a large and beautiful dorsal sepal, white edged; *C. coneolor nitens*, charmingly slender and sweet; *C. Zenobia*, a large and handsome brown pouched variety; *C. Evelyn Ames superbum*; and *C. Hiawatha*.

C. H. Feiling, Esq. (gardener, Mr. C. Hocking), Southgate House, Southgate, contributed a group of the best *Cypripediums*, all especially well grown; and Jeremiah Colman, Esq. (gardener, Mr. W. P. Bound), Gatton Park, Reigate, sent profusely flowered *Cattleyas*.

Messrs. J. Veitch and Sons, Limited, Chelsea, staged two bunches of *Rhubarb Topp's Winter*, the stems of good length, and bright in colour. Also a grand Raspberry named November Abundance, a cross between *Catavisa* and *Superlative*, which displayed large bunches of ripe and green fruits.

From Mr. W. Messenger, Wolverton, Norwich, came good dishes of *Plums Wyedale* and *Wolverstone Orange*.

Mr. W. H. Divers, gardener to the Duke of Rutland, Belvoir Castle, Grantham, staged a large collection of Apples and Pears, which were well developed samples, the Apples being large and in many cases highly coloured. Some of the best Apples were *Dowdney's Seedling*, *Gascoigne's Scarlet*, *Baumann's Red Reinette*, *Sandringham*, *Blenheim Pippin*, *Emperor Alexander*, and *Warner's King*. The Pears were represented by good examples of *Emile d'Heyst*, *Doyenné du Comice*, *Marie Louise d'Uccle*, and *Beurré d'Anjou*.

From the Horticultural College, Swanley, came a large exhibit of fruit and vegetables, displayed with *Vine* and *Ampelopsis* leaves. *Warner's King*, *Peasgood's Nonesuch*, *Cox's Orange Pippin*, *King of Pippins*, and *Bismarck* were amongst the best Apples; while good examples of Pears were *Beurré Diel*, *Louise Bonne de Jersey*, *Beurré Clairgeau*, *Beurré Hardy*, and *Duchesse d'Angoulême*. The vegetables contained some large Leeks, good Student Parsnips, Dobbie's Matchless Turnips, and Savoy.

Mr. H. Becker, Caesarean Nurseries, Jersey, exhibited thirteen fruits of *Pear Belle de Jersey*, weighing thirty-two pounds three and a half ounces. Needless to say, they were veritable monsters, reminding one of a decent Mangold Wurtzel. The largest fruit weighed three pounds eleven ounces.

Mr. A. McKellar, gardener to His Majesty the King, Windsor Castle, staged fourteen Pines in splendid condition and of enormous size, the weights were not given, but they were exceedingly heavy, probably some weighing seven or eight pounds.

A nice fresh box of *Strawberry St. Joseph* came from Mr. A. W. Sutton, Bucklebury Place, Woolhampton, Berks.

Mr. H. Perkins, gardener to the Hon. W. F. D. Smith, M.P., Henley-on-Thames, sent *Strawberry St. Joseph* in pots and boxes. The pots were well fruited, and a capital addition to the dessert table in November.

From Mr. J. H. Goodacre, Elvaston Castle, came bunches of *Diamond Jubilee*, *Imperial Black Seedling*, and *Black Morocco* Grapes. The *Diamond Jubilee* were best in colour and berry.

#### Medals.

FRUIT COMMITTEE.—Silver Banksian Medal to Mr. Henry Perkins, Greenlands, for Strawberries; to Miss Edith Bradly, for collection of bottled fruit; to Harrison and Sons, Leicester, for collection of Onions; to Mr. Becker, Jersey, for Pears. Silver Knightian to Mr. C. Herrin, Swanley, Kent, for collection of fruit and vegetables. Hogg Medal, H.M. the King for fourteen Pine-apples; to Duke of Rutland, The Gardens, Grantham, for Apples and Pears. Cultural Commendation to Arthur Sutton, Berks, for *Strawberry St. Joseph*.

FLORAL COMMITTEE.—Silver-gilt Flora for group of *Chrysanthemums* to Messrs. W. Wells and Co., Redhill; Silver-gilt Banksian for winter flowering *Begonias* to Messrs. J. Veitch and Sons, Limited, Chelsea; Silver Flora for *Carnations* to Mr. H. B. May, Upper Edmonton; for *Zonal Pelargoniums* to Mr. G. B. Gabriel, Woking; Silver Banksian for foliage plants to Mr. J.

Russell, Richmond; for *Conifers*, &c., to Messrs. J. Waterer, Bagshot; for *Chrysanthemums* to Mr. Forster, Nunhead; for cut *Chrysanthemums* to P. R. Dunn, Esq., Brockley Park, Forest Hill.

ORCHID COMMITTEE.—Messrs. Veitch received a Silver Flora C. H. Feiling, do.; Sander and Sons, do.; also Silver Banksian to Sir F. Wigan, Bart.; Capt. Holford, J. G. Fowler, Esq., and H. Low and Co.

#### Certificates and Awards of Merit.

*Apple, Tamplin* (Mr. Basham, Newport).—In appearance, much like the *Crimson Costard*. (Award of Merit.) From Fair Oak Nurseries, Newport, Mon.

*Carnation, Duchess of Portland* (Mr. W. J. Godfrey and Messrs. Cutbush & Sons).—A very free-flowering and fragrant tree, with long stalks, goodly sized flowers of a blush-pink colour, the edges of the petals fringed, and the flower very fragrant. (Award of Merit.)

*Cattleya labiata Amesiana* (J. Bradshaw, Esq., and H. Low & Co.).—A beautiful white variety with broad sepals and protruding lip, nicely fringed and tinted mauve lip. (Award of Merit.) From The Grange, Southgate, N. (gardener, Mr. Geo. Whitelegge), and Bush Hill Park, Middlesex.

*Cattleya* × *Mrs. Pitt* (H. T. Pitt, Esq.).—Parentage, *C. Harrisoniæ* × *C. aurea*. The lip is orange yellow, with pale edge. The sepals and petals are rose-mauve. A stout strong flower. (Award of Merit.) From Stamford Hill.

*Chrysanthemum, Harry Shrimpton* (W. Seward).—A large and massive Jap., russety red above, and old gold beneath. (Award of Merit.)

*Chrysanthemum, Mrs. J. Seward* (W. Seward, Hanwell).—A rich, golden bronze incurved variety. (Award of Merit.)

*Chrysanthemum, S. T. Wright* (Wells & Co., Ltd.).—One of the finest for 1903. Flowers large and strong, petals broad, smooth, well turned back, central ones incurving and showing gold-bronze reverse, and coloured intense crimson-plum. A Jap. (Award of Merit.) From Earlswood Nurseries, Redhill.

*Cypripedium* × *Thalia* (Jas. Veitch & Sons, Ltd.).—Parentage, *C. insigne Chantini* × *C. Baron Schröder*. Beautifully coloured on pouch, petals and sepals with brown, the dorsal sepals with greenish base and white top edges. A very handsome compound hybrid. (Award of Merit.)

*Grape, Imperial Black Seedling* (Mr. J. H. Goodacre).—In appearance like *Black Morocco*, and coloured dark plum. The bunch was a poor one, and we were unable to taste the fruits. (Award of Merit.) From Elvaston Castle, Derby.

*Oncidium Mantini superbum* (F. Wellesley, Esq.).—A large flowered, richly coloured variety; very attractive. Blotched and spotted with deep brown over deep golden yellow. (Award of Merit.) From Westfield Common, Woking.

*Raspberry, November Abundance* (Jas. Veitch & Sons, Ltd.).—A red fruited variety, very free and of good size. (Award of Merit.)

*Rhubarb, Topp's Winter* (J. Veitch & Sons, Ltd.).—A slender stalked, bright crimson-coloured [*Rhubarb*, likely to be good for very late use. (Award of Merit.)

#### National Chrysanthemum, Nov. 4, 5, and 6.

The last of the November shows of this Society was successfully held in the Royal Aquarium, Westminster, on the dates given. The exhibition was as varied as any that have been seen in recent years, and while no one feature was less interesting than hitherto, some of them were decidedly more so. The trade exhibits were highly entertaining, on account of the novelties therein included, and of these we have something to say in another part of this report. A selection of the best flowers on view in our estimation would comprise, among the incurved, *Mrs. R. C. Kingston*, *Globe d'Or*, *Pearl Palace*, *King of the Yellows*, *Mme. Vernieul*, *E. Cannell*, *Duchess of Fife*, *Topaze Orientale*, and *C. H. Curtis*; while the leading Japs in the show were found in *Florence Molyneux*, *Mrs. G. Mileham*, *W. R. Church*, *Mrs. A. R. Knight* (Matthew Smith style) *Australie*, *Mrs. Barkley*, *Sensation*, *Miss Alice Byron*, *Mme. Paola Radaelli* (good), *Mme. Herwege*, *Mr. L. Remy*, *Bessie Godfrey*, *Lord Ludlow*, *Mme. Waldeck-Rousseau*, *Mrs. F. W. Vallis*, *Nellie Pockett*, *Mme. Von Andre*, *E. Molyneux*, *Master C. Seymour*, *J. R. Upton*, and *Godfrey's Pride*.

In the group class Mr. N. Davis was again placed first, and Mr. R. C. Pulling second. Mr. F. S. Vallis was at the head of seven entrants for the forty-eight distinct Japs, with blooms that had been dressed to the last petals, rendering some of the flowers quite out of character, yet perfect, from the florist's or expert's point of view. Such elaborate dressing gives the ordinary grower a false impression of the varieties, and causes him to wonder why his flowers never come like those shown on such stands as Mr. Vallis's. An expert manipulator of the tweezers may also score a large number of points over really a better grower, though we do not at all infer that Mr. Vallis is not both a good grower and an able exhibitor. Mr. Molyneux's remarks in the *Journal* this week, on "Manipulating the Petals," will be read with interest in this connection. The second place in the forty-eight went to Mr. R. Kenyon, of Woodford Green; and third, Mr. A. Jefferies, Meor Hall, Harlow. For the

twenty-four, Mr. W. Mease, of Leatherhead, beat Mr. H. Perkins, of Greenlands.

Plants trained as formal specimens were up to the usual, and here the chief prizewinners were Mr. E. Easey, of Highbury New Park; Mr. F. Gilbert, of Blackheath; and Mr. F. Gilks, of Ponders End. The floral decorations in the galleries seemed more varied than usual, though, even good as they were, an Edinburgh florist severely criticised them. Mr. L. H. Calcutt, of Stoke Newington, led in class 31 for a table of memorial wreaths, anchors, &c., having a huge bell in white Chrysanthemums, and crown beneath it of a yellow variety, the whole being surmounted by an overhead erection, supported by four pillars, and all swathed in flowers. It was too heavy. Messrs. H. Marsh and Son, of Brixton, S.W., came second with Roses, Chrysanthemums, Cattleyas, &c., in their designs; and third, Messrs. Harward Bros., of Balham.

Fruit did not figure largely in the competitive classes. For three bunches of black Grapes, in class 63, Mr. A. B. Wadds, of Paddockhurst, Crawley, led, and Mr. W. Taylor, of Tewkesbury Lodge, came second. Mr. J. Lock, of Weybridge, was first for Muscats, followed by Mr. W. Lintott, of Marden Park, Surrey; while for Gros Colmans, in class 64, Mr. W. Chuck, of Broadsworth Hall, Doncaster, with splendid samples, was premier, and Mr. Taylor again second.

Some shapely vegetables were contributed. Mr. Beckett was a capital leader, out of six, for a collection of nine kinds, grown from seeds supplied by Messrs. Webb and Sons. Messrs. A. Basile, W. L. Bastin, Chas. Brown (Abbot's Langley), and James Hall, of Wells, Somerset, were placed in this order. The first prize was £5. For Mr. Robt. Sydenham's vegetable competitions, the following were the prizewinners: Messrs. A. G. Gentle, R. A. Horspool, A. Basile, J. Hall, R. Lye, C. Brown, and Silas Cole, whose names were each frequently seen on the cards. The first named, who is gardener to Mrs. Denison at a place in Herts, won Mr. Sydenham's Challenge Cup, valued at 15 guineas, for the third time, with an aggregate of fifty-two points, and the cup now becomes his property.

Mr. R. Dean, as secretary to the society, had his hands full.

The following Medal Awards were accorded to non-competitive exhibitors: Mr. H. J. Jones, large Gold; Hobbies, Limited, Gold; H. Cannell and Sons, Gold; W. J. Godfrey, Gold; T. Rochford and Sons, Limited, Gold. Silver-gilt Medals to W. Cutbush and Son; Daniels Bros., Norwich; J. Spink, Walthamstow; W. and J. Brown, Peterborough and Stamford; B. S. Williams and Son; and J. Hill and Son, Edmonton. Silver Medals to G. Boyes, Leicester, and J. Laing and Sons, of Forest Hill.

The display made by the decorated fountains was most imposing. Each exhibitor has half of each fountain, and while making a grand feature, it gives the competitors great scope for displaying their artistic taste. The prizes, which are given by the president, Sir Albert Rollit, M.P., are sufficient to attract our best exhibitors. On this occasion there were three competitors. The first honours fell to Mr. Norman Davis, Framfield, who certainly made the most of his opportunities. Apart from the Chrysanthemums, a great wealth of foliage was employed, both as plants and in a cut state. Palms, Dracenas, Crotons, Asparagus, Ferns, and Smilax were liberally employed, and with good taste. The Chrysanthemums, however, were beautiful, Madame P. Radaelli, Duchess of Sutherland, George Lawrence, Madame W. Rosseau, Calvat's Sun, Miss Mildred Ware, and Madame Carnot being especially fine. Mr. R. C. Pulling, Monkham's Nurseries, Woodford Green, made a grand second, and his exhibit was certainly conceived in bolder style. Huge pyramids of Mrs. Barkley and W. R. Church were grand, while most of the other flowers employed were fit for the exhibition tables. The foliage was also employed tastefully, and the exhibit must have been remarkably close to the first prizewinner. The third position was awarded to Mr. Jas. Lock, gardener to the Hon. Mr. Justice Swinfen Eady, Weybridge, who certainly made a good, vigorous exhibit, which possessed plenty of character in design, and was well carried out in the best decorative style.

#### Plants.

The competition for six bush specimens, large flowered varieties, only brought out one exhibit, that from Mr. W. Noble, gardener to H. J. Pitt, Esq., Rosslyn, Stamford Hill, who had good plants of Lady Hanham, Vivian Morel, and Phœbus.

Class 3 was for four trained specimen plants, any varieties, only brought out one entry. Mr. E. Easey, gardener to F. Bishop, Esq., The Grange, Highbury New Park, was the only competitor, and was deservedly awarded the first prize; his varieties were Miss Watson, Colonel W. B. Smith, President Nonin, and Commandant Blussett.

The trained pompons brought out two good exhibits, the first prize being taken by Mr. F. Gilbert, who had four large plants well flowered with beautiful foliage; his varieties were Toussaint Maurisot, Wm. Westlake, Abre de Noël, and Pygmalion. Mr. F. Gilks was second with more closely trained plants; his best plants were Nellie Rainford and Rosinante.

For one specimen plant, any variety, there were four entries, the first prize being awarded to Mr. E. Easey, gardener to F. Bishop, Esq., The Grange, Highbury New Park, for a grand plant of Miss Watson, simply covered with its bright yellow flowers. Mr. F. Gilbert, gardener to M. N. Buttershaw, Esq., Kendal House, Blackheath Park, was second with Rosinante, a pink pompon; while Mr. F. Gilks, gardener to F. W. Freir, Esq., Bylock Hall, Ponders End, was third with La Triomphante.

#### Challenge Trophy.

The Challenge Trophy for Chrysanthemum societies is always one of great interest, and excites keen competition. It is rather a tall order to produce forty-eight Japanese and twenty-four incurved blooms, but it is always done with credit to the societies, and the additional prizes of £10, £6, and £4 to the winners ensure good competition as a general rule; but on this occasion only one society staged, the Epsom and District Society, and the exhibitors were Mr. G. Hunt and Mr. W. Higgs. The exhibit was undoubtedly a strong one, and would have stood high had there been a competition, the varieties were, Japanese: Florence Molyneux, Mrs. Geo. Mileham, Matthew Smith, Pride of Madford, Mrs. W. Popham, Marquise V. Venosta, Mrs. H. Weeks, Mafeking Hero, Mrs. J. J. Thornycroft, Mermaid, Mr. T. Carrington, Miss E. Fulton, W. R. Church, Jane Molyneux, Rev. W. Wilks, Madame Herrewége, Mrs. C. H. Payne, Mr. L. Remy, Calvat's 99, Mr. G. Carpenter, Mrs. Hummell, Swanley Giant, Mrs. Greenfield, and Australia. The incurved varieties were Duchess of Fife, Pantia Ralli, Countess of Warwick, Mrs. W. Howe, Topaze Orientale, Globe d'Or, Lady Isobel, Ialene, Nellie Southam, Edith Hughes, Miss Doris Cox, Mr. R. C. Kingston, Dorothy Foster, Ernest Cannell, Miss R. Hunt, Chas. H. Curtis, Louisa Giles, Robert Petfield, J. Agate, Madame Durandal, Golden Empress, Pearl Palace, Hanwell Glory, and Dome d'Or.

#### Cut Blooms.

The premier class for incurveds is represented by thirty-six distinct, and there were three exhibitors who faced the judges. This and the following class are for the Holmes Memorial Challenge Cups. Here Mr. W. Higgs scored first prize with a strong, even stand. His varieties were, back row: Mrs. C. Crooks, Frank Hammond, Major Bonaffon, Mr. R. C. Kingston, George Lock, Topaze Orientale, The King, Lady Isobel, Robert Petfield, Ernest Cannell, Duchess of Fife, and Nellie Southam; middle row: Ialene, J. Agate, Miss Doris Cox, George Haigh, Cecil Cutts, Wm. Higgs, Comtesse de Estoile, Countess of Warwick, Lord Alcester, Madam Vernieul, Madame Durandal, and Chas. H. Curtis; front row: Edith Hughes, Violet Foster, Globe d'Or, John Lambert, Pearl Palace, Golden Empress, Hanwell Glory, Louisa Giles, Creole, King of the Yellows, Empress of India, and Dome d'Or. Mr. G. J. Hunt made a good bid for second place, his best blooms being Ialene, Violet Tomlin, Baron Hirsch, Chas. H. Curtis, and Duchess of Fife; and Mr. W. Mease third.

The competition for the forty-eight varieties was exceedingly keen, there being no less than seven competitors, the first place being awarded to Mr. F. S. Vallis, Broomham Fruit Co., Chippenham. His blooms were undoubtedly grand in size and colour. The varieties were, back row, reading from left to right: Mon. Waldeck-Rosseau, Kimberley, Mrs. J. Bryant, Madame Herrewége, Phœbus, Mrs. R. Darby, Madame Phillippe Rivoire, Mrs. B. Wyld, Marquis V. Venosta, Madame P. Ralli, Matthew Smith, Australia, F. S. Vallis, Chas. Longley, Mrs. J. Lewis, and Ed. Molyneux; second row: Mrs. Barkley, Duchess of Northumberland, Mrs. T. W. Pockett, Lily Mountford, W. R. Church (grand), Madame Carnot, Mrs. G. Golder, Seedling, Le Grand Dragon, Mr. T. Carrington, Mrs. Greenfield, Henry Weeks, Nellie Bean, Miss Alice Byron, Seedling, and G. J. Warren; front row: Duchess of Sutherland, Mrs. F. W. Vallis, Mrs. G. Mileham, Mrs. H. Weeks, Bessie Godfrey, Pride of Madford, Mons. Chenon de Leché, Mrs. E. Hummell, Mrs. Mease, Sensation, Nellie Pockett, Henry Stowe, Ethel Fitzroy, Mrs. Coombes, Mons. L. Remy, and Calvat's 99. Mr. R. Kenyon, gardener to A. F. Hills, Esq., Monkham's, Woodford Green, made a bold bid for second place. His best blooms were W. H. Whitehouse, Le Grand Dragon, Lord Alverstone, Miss Elsie Fulton (grand), Mrs. W. Popham, Madam Von Andre, Mrs. Barkley, and Mafeking Hero; and Mr. A. Jeffries, gardener to John Balfour, Esq., Moor Hall, Harlow, was third with a good display, while Mr. W. Mease, gardener to A. Tate, Esq., Downside, Leatherhead, was fourth.

The Great Vase class is now so well known as one of the chief attractions at the National Show that no wonder there should be such a grand display. The schedule reads twelve vases of five blooms each, one variety to each vase. The latter are provided by the Society, and are uniform throughout. The prizes start at £20, and drop in fives until the unit is reached. Four exhibitors competed, Mr. F. S. Vallis once more coming out the victor; but the blooms did not strike one as being up to the average of those last year. The varieties employed were

Madame Herrewége, Mons. Chenon de Leché, Australie (grand), Mrs. Mease, W. R. Church, Calvat's '99, Le Grand Dragon, Madame Carnot, Mrs. Barkley, M. L. Remy, Edwin Molyneux (as good as ever), and Mrs. J. Lewis. Mr. Chas. Beckett, gardener to Sir W. G. Pearce, Bart., Chilton Lodge, Hungerford, was a good second, the varieties employed being Madame P. Radaelli, Loveliness, Mrs. J. Bryant, Miss Alice Byron, Sensation, Madame Carnot, Mrs. Coombes, Mrs. Mease, Godfrey's Pride, Mrs. H. Weeks, J. R. Upton, and Mrs. Barkley. Mr. W. C. Meredith, gardener to G. Wilder, Esq., Stanstead Park, Emsworth, was third, and Mr. Geo. Williams, Manor House Nursery, Cardiff, fourth.

Class II was for twenty-four blooms, distinct, and a grand entry of eleven exhibitors staged in a truly strong class. Mr. H. Perkins scored first, his varieties were Henry Perkins, Edith Smith, General Buller, Australie, George Lawrence, Mrs. J. Bryant, Graphic, W. H. Whitehouse, Mrs. J. C. Neville, Vicar of Leatherhead, Mrs. J. Cleeve, Earl of Harrowby, Lady Mary Conyers, Edith Tabor, Mrs. G. Mileham, Lady Aeland, Mary Perkins, W. R. Church, Countess of Harrowby, Viscountess Cranbourne, Mrs. R. Darby, Countess of Arran, Mrs. J. W. Barks, and Madame Herrewége; Mr. W. Mease followed with nice blooms of George Lawrence, Mrs. J. C. Neville, Florence Molyneux, Mafeking Hero, Mr. L. Remy, and J. R. Upton, while Mr. Alex. Smith, gardener to the Lady Superior, The Convent, Roehampton, was a nice third; and Mr. A. Jefferies fourth.

The boards for twelve blooms, distinct, proved an attractive one for exhibitors, there being no less than fifteen competitors faced the judges. The first honours going to Mr. H. Perkins, gardener to the Hon. W. F. D. Smith, Greenlands, Henley-on-Thames, who had a strong beard of blooms, the varieties being Henry Perkins, Australie, George Lawrence, Lady Mary Conyers, Mrs. J. Cleeve, Mrs. W. Popham, Mrs. J. Bryant, Phœbus, Mrs. J. C. Neville, W. R. Church, Madame Herrewége, and Mrs. G. Mileham. Mr. George Hewitt, gardener to C. E. Green, Esq., Theydon Grove, Epping, followed with good blooms of W. R. Church, Mons. Chenon de Leché, Mrs. Mease, and Mrs. Barkley. Mr. W. L. Bastin, gardener to Sir Alex. Henderson, Bart. M.P., Buscot Park, Farringdon, was third, and Mr. G. Impey, gardener to H. Mansfield, Esq., New Barnet, brought up the rear.

For a vase containing six blooms of any white Japanese variety there were seven entries. Mr. W. Mease winning first prize with a good vase of Princess Alice de Monaco. Mr. W. C. Meredith came next with a good display of Madame Gustave Henry, Mr. J. Sandford was third with the same variety, and Mr. C. Lane, gardener to E. H. Coles, Esq., Caterham, brought up the rear with good Miss Alice Byron.

A similar class for six yellow blooms produced six entries. Mr. H. Perkins taking first position with a glorious vase of Viscountess Cranbourne; Mr. Charles Edwardes, gardener to H. W. Peal, Esq., Ealing, was second with rich blooms of R. Hooper Pearson. Mr. Lane came next with Mrs. W. Mease, and Mr. H. Parr, gardener to F. A. Bevan, Esq., Trent Park, New Barnet, was fourth with Edith Tabor.

All the other colours were lumped together in one class, and six exhibitors staged, the first prize going to a grand vase of Mrs. Barkley from Mr. A. Jefferies; Mr. H. Perkins was a good second with Australie; while Mr. G. Hewitt was third with beautifully coloured W. R. Church, and Mr. W. L. Bastin was fourth with Mrs. G. Mileham.

The hairy petalled varieties were exhibited in a vase containing six blooms in not less than two varieties, but, sad to relate, only two entries were made, Mr. Henry Love, Sandown, Isle of Wight, being first with a fair vase containing Princess Henry, Louis Boehmer, and a seedling; and Mr. S. Foster, gardener to R. Nivison, Esq., Hendon, followed with Mrs. D. Ward, Hairy Wonder, and King of Hirsutes.

A most interesting class was that for six vases of incurved blooms in six distinct varieties of five blooms each. Those who deprecate the incurved blooms as being unsuitable for decorative purposes had an object lesson here, which would, no doubt, cause them to alter their opinion. There were three exhibits, and the champion, Mr. W. Higgs, gardener to J. B. Hankey, Esq., Fetcham Park, Fetcham, added to his honours by taking the blue ribbon once more, with a superb exhibit. His varieties were Robert Petfield, Mrs. R. C. Kingston, Hanwell Glory, Lady Isobel, Nellie Southam (superb), and Charles H. Curtis. Mr. G. J. Hunt, gardener to P. Ralli, Esq., Epsom, was second with good vases of Mrs. W. C. Egan, Globe d'Or, Chrysanthemiste Bruant, and Empress of India. Mr. W. L. Bastin came in third with Lady Isobel, Hanwell Glory, and Baron Hirsch as his best examples.

For twelve blooms incurved, distinct, there were nine entries. Mr. W. Higgs again taking the premier award with a nice even board. The varieties were Topaze Orientale, Ernest Cannell, Madame Durandal, Duchess of Fife, Lady Isobel, Nellie Southam, J. Agate, Ialene, Golden Empress, Globe d'Or, Robert Petfield, and Charles H. Curtis. Mr. W. L. Bastin was a good level second, his best blooms being Lady Isobel, J. Agate, Duchess of Fife, Baron Hirsch and Dorothy Foster. Mr. C. Lane was third, and Mr. Charles Edwardes fourth.

Class 19 was for six blooms incurved, one variety only, and there were eight exhibits, Mr. W. Mease securing the premier place with a good exhibit of Topaze Orientale, Mr. Charles Crooks, gardener to the Dowager Lady Hindlip, Droitwich, being second with Duchess of Fife, and Mr. J. Sandford third with Charles H. Curtis.

A market growers' class was provided for six varieties, such as are grown for market, six sprays to form a bunch, not disbudded, exhibited in vases. There were three competitors, who would have made a sorry display in market. Where are the growers? The first prize was allotted to Mr. J. R. Allen, gardener to C. A. Morris Field, Esq., Tunbridge Wells, who staged Mons. E. V. Freeman, Mrs. Wingfield, Soleil d'Octobre, Mychett Beauty, Crimson Pride, and Notaire Glory. Mr. H. Parr was awarded second; and the other was evidently not deemed worthy of a prize.

There was only one class for the reflexed varieties; twelve blooms, not less than nine varieties. Here there were only two exhibits, the first prize being awarded to Mr. T. Caryl for a moderate board. His varieties were Dorothy Gibson, King of Crimsons, Pink Christine, Mrs. Forsyth, Golden Christine, Phidias, Cloth of Gold, Cullingfordi, Miss F. Lunn, and Cloth of Gold. Mr. Charles Brown was second.

For twenty-four large flowered Anemone C's, Japanese included, distinct, there was only two exhibits from Mr. Charles Brown, who staged good blooms of Delaware, Descartes, Mabel Miller, Mrs. Judge Benedict, and Gluck. Mr. A. Page was a good second with good examples of Descartes and Mons. Panckoucke.

The elder type of Anemones were arranged in vases, six blooms in each. Here Mr. Charles Brown was again first with two pretty vases, followed by Mr. A. Page.

A similar class was provided for the Japanese Anemones, which brought out three exhibits. The first prize was awarded to Mr. Charles Brown, gardener to R. Henty, Esq., Langley House, who had good blooms of Owen's Perfection, John Bunyan, Madame Lawton, and Sir W. Raleigh. Mr. J. Barrance, gardener to G. W. Taylor, Esq., Hadley Bourne, Barnet, was a close second; and Mr. A. Page, gardener to G. W. Kilner, Esq., Ravenscroft, North Finchley, brought up the rear.

Five entered in class 28 for prizes offered by Mr. W. J. Godfrey, the flowers to be selected from the Exmouth novelties of 1901 and 1902. These collections were, without doubt, the most richly coloured in the show, most of the blooms being either crimsons, bronzes, or rich deep yellows. Mr. Kenyon led for 12, followed by Mr. C. Ritchings, gardener to the Misses Baird, St. James', West Malvern; and Mr. C. Beckett, gardener to Sir W. G. Pearce, Bart., Chilton Lodge, Hungerford, in this order; five competing. The best blooms from the foregoing were Godfrey's Pride, H. E. Hayman, Sensation, Loveliness, W. E. Vowden (a bronzy incurving Jap), and Exmouth Crimson. Mr. A. Jefferies, of Moor Hall, led, and Mr. A. Shipway followed for a vase of three of the Exmouth novelties.

We have already referred to the prizewinners in class 31, for a table of floral designs, and would add that the prizes were offered by Mr. J. T. Simpson, his friends, and market growers of flowers. The succeeding class, for three epergnes of Chrysanthemums and suitable foliage, brought out seven sets, making twenty-one epergnes. Mr. J. French, gardener to Mrs. Barclay, Ambleside, Wimbledon Park, was placed first; Miss C. B. Cole, Feltham, second; and Mrs. Green, of Harold Wood, third.

AMATEURS' CLASSES.—A fair show was made in this section. For eighteen Japs, Mr. J. Childs, The Priory, Totteridge, was first; Mr. A. Page, North Finchley, second; and Mr. C. H. Martin, Raymead, I.W., third, there being only three sets. Five entered for the twelve, the winners being Mr. M. Rayment, of Romford; Mr. L. Gocch, South Norwood; and Mr. A. Page, placed thus. Class 39, for the six Japs, brought up ten entrants, and here Mr. A. Robertson, of St. John's Wood, was first; Mr. H. Pestell, Bedford, second; and Mr. J. Childs third. For six of one variety, Mr. A. Robertson led with W. R. Church. The incurveds were poor.

The usual disappointing display of decorative Chrysanthemums, in competition for Mr. Percy Waterer's Silver Challenge Cup (class 45), was presented as a feature on this occasion. We should like to see these classes much more enlarged, so that truly representative groups might be seen, and the section is worthy of more consideration in point of space allowed. Four entrants were forward, the prizes falling to Messrs. D. B. Crane, of Highgate, with a bright lot, but poorly staged, as were those of the others—to wit, Percy L. Johnson, North Gate, Bishops Stortford, second; and A. Taylor, of East Finchley, who came third.

In class 46, for a very similar display, Mr. Crane again led, and Mr. A. Taylor was second, there being no other exhibitor.

For the twelve distinct Japs in class 48, an even board was set up by Mr. M. Silsbury, of Providence, Shanklin, Isle of Wight, though some of them could have been more fully developed. However, they were easily first. A handsome flower of Sunshine was included. This is a massive flower, with plenty of material in it, the florets drooping but turned up at the tips, and coloured rich ruddy gold. He also staged a good bronzy-red seedling of great breadth of petal, and other flowers not often seen at

their best. The second place fell to Mr. Geo. Heal, Holly House, Compton, with very fair flowers, but loosely built, except Hero of Omdurman. Lord Ludlow was very deeply coloured, and a little out of character. Mr. F. Sharpe was third, having a rich R. Hooper Pearson, which seems too intensely coloured to go well with other flowers. This class brought forth nine contestants, who staged an aggregate of 108 blooms, the first being only a Silver Medal and 20s.

For three Japs distinct the forewinner was Mr. P. Towers West Hambleton, Henley-on-Thames, with three novelties—W. R. Church, Earl of Arran, and Geo. Lawrence. Mr. F. Wheatley, of Thames Street, Weybridge, was second. For six Japs, distinct, Mr. F. Wheatley staged large and well-built flowers; Mrs. Pockett and Mrs. G. Mileham, being good; and also Nellie Pockett. For a dozen incurved blooms in class 51, Mr. T. Sharpe, of Greenhithe, was placed first, but had a very ragged set, Miss A. Hills and Topaze Orientale being fair blooms, but requiring to be dressed. Mr. Sharpe's six in three varieties, class 50, were creditable, though too ragged, except Royal Standard, which was almost perfect.

Class 60, for a vase of six blooms of any Jap, arranged with foliage, resulted in a keen competition, nine staging. Mr. E. Jones, of 51, Bower Street, Bedford, was deservedly first with good blooms, assisted by purple Oak sprays and green Chrysanthemum foliage; Mr. C. H. Martin, Raymead, Hendon, was an excellent second; and third, Mr. A. Robertson, of St. John's Wood. In class 35, for a vase of six blooms, one variety, the honours fell to Mr. H. Perkins, of Greenlands; and Mr. H. Parr, of Trent Park, second. Mr. F. A. Coote, Bechfield, Weybridge, was a poor third. Four entered. For two vases of pompons only a couple of entrants were forward, Mr. W. C. Pagram, of The Whin, Weybridge, being first, with a nice fine arrangement; and Mr. W. Grundy, Orchard Leigh, Rotherhithe, second, with an ugly, compact, bouquet-like mass, which would repel any lover of the graceful in flowers from using pompons. Mr. Pagram's were really pleasing, though less dried grass might have served.

#### Non-competitive Exhibits.

Mr. H. J. Jones, Ryecroft Nursery, Lewisham, was exceedingly well represented, having a very large group, and the flowers were of the highest quality. His chief novelties were Miss Mildred Grant, of a ruddy-flesh and creamy combination of colour. This has had two F.C.C.'s. Henry Perkins was also shown. It is a rich crimson. Nellie Perkins, purple and white; Hon. Mrs. Acland, incurved bright golden; Geo. Lawrence, Ben Wells, Earl of Arran, and Nellie Bean. His exhibit occupied the whole west end of the Aquarium.

Messrs. B. S. Williams and Son, Upper Holloway, N., sent Verbena Miss Wilmot, retarded Spiræas, with Ericas, Liliums, and foliage plants and Orchids in flower.

Hobbies, Limited, from Dereham, furnished a very beautiful display of artistic merit, and included many very fine exhibition Chrysanthemums.

Messrs. Cannell and Sons, Swanley, staged in their usual place a double table length of specimen flowers, including the following, among others: Marquis V. Venosta; Sensation (grand colour); Mr. F. S. Vallis, plenty of substance; Mrs. A. Tuckett; W. R. Church; Lord Hopetoun (1903), a grandly coloured novelty, bright deep crimson above and old-gold reverse; Mme. Paola Radaelli; General Hutton; and Mermaid. They had also a superb collection of Zonal Pelargoniums, Violets, and Lorraine Begonias in variety.

Messrs. I. House and Sons, Westbury-on-Trym, contributed Violets in the varieties Luxonne, Marie Louise, St. Helena, Baroness de Rothschild, an improved Luxonne, being stouter, darker, and bigger in every way. Le Lilas, a purple; White Czar, pure white; Princess Beatrice; Comte de Brazza; Armidemi Millet, with variegated foliage; and Nana compacta, a very hardy one; and Mrs. J. J. Astor, that fine double purple.

Mr. W. J. Godfrey, Exmouth, Devon, sent an enormous collection of his famous southern flowers. In his stand were Exmouth Rival (rich and full); Mr. F. S. Vallis, of huge size; Sensation (grand colour); Godfrey's King; Triumph; H. E. Hayman, a grand thing; Miss E. Fulton; Exmouth Crimson; Duke of Devonshire, a large ruddy yellow flower; Loveliness, a big, "swirl-formed," soft yellow, with very broad petals; Charming, one of the finest yellows, with drooping florets; Wilfred H. Godfrey, a sweet flower, crimson above, with incurving tips coloured bronze; with Grandeur and Bessie Godfrey. Carnations were also included.

Messrs. T. Rochford and Sons, Limited, Broxbourne, Herts, were represented by a large and varied stock of retarded stuff, consisting of Lilies, Lily of the Valley, Spiræas, Azaleas, and Palms, with grouplets of that best of red-coloured winter-flowering Roses, Liberty.

Mr. J. Spinks, Summit Road Nursery, Walthamstow, E., and Messrs. J. Peed and Son staged groups of Chrysanthemums. Messrs. G. Boyes and Co., Aylestone Nurseries, Leicester, contributed a rich variety of tree Carnations, including Lady Carlisle, fringed pink; Mrs. Lawson; Duchess of Fife; and Lord Kitchener, the freest blooming winter variety they—Messrs. Boyes—have, coloured dark crimson.

Messrs. W. and J. Brown, Stamford, were strong in Apples, Pears, and other fruits, together with the Fire Dragon Geranium, Gloire de Lorraine Begonia, Heliotropes, and Rose Gloire de Polyanthes.

Mr. Vincent Slade, Taunton, Somerset, contributed Zonal Pelargoniums in the following chief sorts: Lord Roberts, Lord Curzon, Mary Beton, Barbara Hope, the Khalifa, President McKinlay, Scott Turner, Cerise, Ian MacLaren, and J. M. Barrie.

Messrs. H. Cannell and Sons, Swanley, Kent, sent a kingly collection of Apples, in which there were some very excellent samples of Lord Derby, Emperor Alexander, Stirling Castle, Bramley's Seedling, Blenheim Orange, Gascoyne's Scarlet, and the leading kinds in general.

Mr. H. Tyler, The Mead, Child's Hill, near Kilburn, N.W., staged nice blocks of his noted Mushroom spawn.

From Norwich, Messrs. Daniels, Bros., Limited, presented a very varied representation of vegetables. Their Crimson Perfection Beet was a model of good culture; Potatoes, Royal Sovereign and Up-to-Date; Champion Leek, White Spanish and Ailsa Craig Onions; Improved Hollow-crown Parsnips, and Daniels' King Cauliflower were each seen to great advantage.

Mr. J. George, 14, Redgrave Road, Putney, S.W., set up some sundries-men's specialities in Thomson's Vine Manure, Nicotine Fumigator, and Mushroom Spawn. Messrs. Dowell and Son of Hamme Smith had pots, labels, fertilisers, &c.

Horticultural sundries were very largely represented by Messrs. Wood and Son of Wood Green, N., who staged their Voltha Emulsion fungicide; their Orchid peat, specially prepared; with raffia, stakes, lawn mowers, turf maul, watering pots, baskets, fancy and for garden use; gloves, labels, twine, and wire baskets.

From Messrs. Cutbush and Son, Highgate, London, N., came Malmaison Carnations, Sir Charles Fremantle being prominent; also Verbena Miss Ellen Wilmott, retarded Spiræas, Ericas, tree Carnations, Liliums, Vines, and foliage plants.

Messrs. Pearce and Co., Holloway Road, London, were forward here with their well-built model greenhouses, frames, and stoves. The firm received a silver medal for their exhibit at the Alexandra Palace a day or two previously.

Messrs. Fenton and Son, Tudor Street, Whitefriars, E.C., had greenhouse hot water apparatus in various styles; and from Mr. Jas. Arnold, 32, St. Paul's Road, Camden Town, N.W., came samples of loams and sand. The Ichthemio Guano Co., Ipswich, had samples of their fertilisers. Messrs. Lawes, of 59, Mark Lane, London, showed their chemical manures; as did the Permanent Nitrate Co.

The "Pattison" Patent Lawn Boots were again brought forward. These are of exceedingly good quality and make.

Mr. H. Love, 1, Melville Terrace, Sandown, I.W., contributed a goodly set of blooms, and Mr. W. Seward of Hanwell had a number of seedling novelties. Mr. J. Russell had Eurya latifolia and Crateguses, together with a collection of Apples. Messrs. J. Laing and Sons, The Nurseries, Forest Hill, S.E., also had a nice table of fruits, Apples principally.

Ferns were grandly exhibited by Messrs. J. Hill and Son, Barrowfield Nurseries, Lower Edmonton. The group was admirably arranged, and fine stuff were included, the chief features being Adiantum Capillus-Veneris imbricatum, A. macrophyllum, A. Collisi, Nephrolepis pectinata, Lygodium scandens, and fine pieces of Elk's-horn Ferns, with specimen Gymnogrammas.

#### Portsmouth, October 29.

The annual show was held in the Town Hall. The entries were not so numerous as in the past. The cut blooms exhibited the result of a backward season; many were but partially developed. Plants were similarly weak. Fruit and vegetables were numerous and good. Japanese cut blooms formed the most important part of the show. The principal class was that for forty-eight, in not less than two dozen varieties. Only two competed, the best coming from Mr. C. Penford, gardener to Sir F. Fitzwygram, Bart., Leigh Park, Havant. In numerous instances here the blooms were but partly expanded, the most noteworthy being General Buller, Florence Molyneux, The Princess, Duchess of Sutherland, George Penford, Le Grand Dragon, F. Smith, J. Penford, W. R. Church, and C. Penford, the latter a semi-incurving variety of pleasing colour, buff base, with dull red stripes and suffusion. Mr. J. Agate, Brockhampton Nurseries, Havant, was second.

In the class for twenty-four in not less than twelve kinds, the competition was more brisk; four staged, all creditably, the best coming from Mr. J. Love, Park Road, Cowes—an even set, of which the following were conspicuous: M. Chenon de Leché, Nellie Pockett, Lily Monmouth, Lord Ludlow, Phœbus, and Lady Hanham. Mr. W. G. Adams, 89, Clarendon Road, Southsea, a close second.

Mr. J. Tosh Robb, Woolston, secured the coveted award for twelve distinct with quite a creditable set. Mr. C. E. Creighton, Stanswood, Cowes, second, with Mr. T. Williams, Queen's Crescent, Portsmouth, third. Incurved varieties were poor.

For thirty-six, Mr. J. Agate was the only exhibitor, winning first place. Such varieties as Major Matthews, Edith Hughes, Miss A. Hills, D. B. Crane, and Jeanne d'Arc were creditably staged.

The next class, that for twenty-four incurved, showed better quality. The blooms were more developed, Mr. Adams winning first place easily with Baron Hirsch, D. B. Crane, C. H. Curtis, and Globe d'Or, creditably staged. Mr. C. White, 6, Garden Terrace, Southsea, second. Mr. J. Love won for six distinct, Mr. C. White second. In the class for a bouquet of Chrysanthemums seven entered, making a pleasing feature in the show. Miss Peel won with a pleasing arrangement of yellow. Mr. Sackett second. A class was set apart for table decoration, open to ladies only. Amongst five competitors, Mrs. R. Jefferies, Nursling, Southampton, secured the premier award for a lightly arranged design. Mrs. W. H. Berry, Portsmouth, a close second. Mrs. L. Fay, 242, Commercial Road, Landport, third. Plants were few in number. Mr. Burridge, North End Nurseries, won the first prize for a combination of Chrysanthemums and foliage plants, all too much crowded.

Apples and Pears were well staged. Mark Gill, Esq., 82, Osborne Road, Southsea, won for eight dishes in the former section, while Mr. C. Dear occupied a similar position for Pears. Vegetables were numerous and good. Mr. W. Cheaton, gardener to Sir W. King, Shrover Hall, Cosham, secured the leading award for nine dishes, with good produce.

### Kent County Chrysanthemum, October 29 and 30.

A bright display, though a shade smaller than in some former years, was on view at The Rink, Blackheath, S.E., as above dated. Decidedly the best flowers were those seen in class 2, for eighteen each of Japs and incurveds. Mr. C. Payne, gardener to C. J. Whittington, Esq., Sandhills, Betchworth, Surrey, was placed first, and staged handsome blooms of General Buller, Mrs. Gustave Henry, Mrs. G. Mileham, Master C. Seymour, Lord Ludlow, and Princess Alice de Monaco. These were the best, the others, as follows, being smaller: Mrs. Coombes, Mrs. White Popham, Edith Tabor, Marquis V. Venosta, Mrs. F. E. Smith, Mr. T. Carrington, Jane Molyneux, James Bideneope, Mrs. F. Greenfield, Mrs. R. Darby, and Blanda. The best incurveds were Baron Hirsch, Dome d'Or, Jeanne d'Or, Topaze Orientale, and Matthew Russell. The second place here was accorded to Mr. F. Tapper, gardener to Sir Samuel Scott, Sundridge Park, Bromley, with really good blooms of W. R. Church, Mr. L. Remy, Marquis V. Venosta, Lord Ludlow, Mrs. R. Darby (excellent), and Mrs. Mileham. His incurveds were of fair size, but very irregular. Third came Mr. H. C. Strickland, gardener to Sidney Smith, Esq., Clovelly, Grove Park, with much smaller flower, and none could be called of high merit.

The twenty-four Japs, distinct, brought only one entry; this from Mr. J. E. Poole, gardener to A. G. Hubbuck, Esq., Elmstead Lodge, Chislehurst, whose finest flowers were W. R. Church, Mrs. Barkley, Henry James (good), and General Buller. For the twelve Japs, Mr. J. Lyne, gardener to H. F. Tiarks, Esq., president of the society, Foxbury, Chislehurst, led, his only opposer being Mr. C. Bellis, gardener to Mrs. G. M. Faulkner, Fonthill Lodge, Forest Hill, S.E., but both sets were a long way below the higher exhibition standard. Mr. Lyne was alone in class 5 for twelve incurveds, having a very good bloom of Mme. Ferlat, though rather loosely built; but the others were faulty and ill-dressed.

One of the best classes in the show was that for twelve reflexed Chrysanthemums, in six varieties. The flowers were of fair size, and included Dorothy Gibson, Aureole, King of Crimson, Chas. Tutt, and Amy Furse in Mr. J. E. Poole's first prize set. Mr. T. E. Cauldrey, gardener to W. Watson, Esq., Woodstock Grove Park, Lee, was second. For twelve pompons, in bunches of three, two came forward, viz., Mr. F. Gilbert, of Kendal House, Blackheath (first), and Mr. W. Pascoe, of Baston Manor, Hayes. In the leading set were the varieties W. Sabey, Rosinante, W. Kennedy, Abre de Noel, Maid of Kent, Jeanne Hachette, Pygmalion, and President. Mr. G. D. Judge, with Jane Molyneux, had the best (and only) six white Japs, staging superb flowers. Mr. T. E. Cauldrey was represented for "any coloured sort" by Mrs. White Popham; and Mr. Strickland staged Mr. E. Bennett, and got first for six of the incurved variety.

Mr. L. Humphrey, The Hawthorns, Lewisham, was first for an epergne of the flower, and Mr. A. W. Hollands, Lee Park, second. In the previous class, for a hand bouquet, Mr. C. Townsend, the Lee Floral Stores, staged the best arrangement, Mrs. L. Humphrey coming second.

Mr. J. Lyne was first of two for a group of flowering and foliage plants, having Crotons, Cattleyas, Ferns, &c. Mr. W. Heath, gardener to C. Cutler, Esq., 11, St. John's Road, was second. Mr. A. W. Holland, Lee Park Nursery, led for a group of Chrysanthemums. In the amateurs' classes, Mr. G. C. Farmer and Mr. E. A. Watts had the honours all to themselves. Mr. W. Taylor, of Tewkesbury Lodge, led for both black and white Grapes; while in the Apple and Pear competitions, Messrs. Lyne, Farmer, and J. A. Baker portioned the spoils.

The best Japanese bloom in the show was Mrs. G. Mileham, from Mr. D. Jude; while the premier incurved was Lady Isobel, from Mr. T. E. Cauldrey. In class 41, for a collection of six kinds of vegetables, the winners were Messrs. Humphrey, Lyne, and Musson.

Amongst those who staged non-competitive groups were Mr. H. J. Jones, Ryecroft, Lewisham, who had some new varieties, and received certificates for three of them, namely, Edith Smith (creamy-white), Henry Perkins (purplish and gold), and Mildred Ware (tawny red). He was awarded a silver-gilt medal. Mr. J. Surman, Victoria Nursery, Beckenham, had also a comprehensive group, and received a similar award; while, for a stand of odorous Violets, Messrs. I. House and Son, Westbury-on-Trym, near Bristol, had a silver medal; likewise Messrs. J. Peed and Son, West Norwood, for a good collection of Apples; and Messrs. Dover and Co., of Blackheath, the same for floral designs. Successful concerts were held on both evenings of the show, the Metzner Orchestra supplying the music. Mr. F. Fox, gardener at The Cedars, Lee, who is hon. sec. to the society, deserves high commendation.

Apple, Riva<sup>1</sup>.

(See page 428.)

### Woolwich, October 30 and 31.

This society, which has now been established several years, and holds a summer show in July and a Chrysanthemum one in the autumn, had its usual exhibition in the spacious Drill Hall in Beresford, and a very good display was seen. A good deal of local éclat was given to the proceedings from the fact that Lady Charles Beresford, the wife of the member for the borough, attended and declared the show open at 3 p.m., Lord Charles Beresford charming the company with a pleasant and sympathetic speech.

In the open classes there were two for groups, one of Chrysanthemums and foliage plants, and one for flowering plants. Those staged were somewhat of a mediocre character. The class for 24 blooms of Japanese brought two good collections. Mr. R. Kenyon, gardener to A. F. Hills, Esq., Monkham, Woodford, was placed first with very good blooms of Miss Alice Byron, selected by the judges as the best specimen bloom of Japanese in the open classes; Mrs. Barkley, Lord Ludlow, Bronze Solèil d'Octobre, Madame Herwege, a white sport from Australie, Mrs. T. W. Pockett, Pride of Madford, Lily Mountford, W. R. Church, Madame G. Henry, Madame G. Bruant, &c. Mr. J. Simon, gardener to W. R. Mann, Esq., Bexley, was a very good second. He had in good form Lord Roberts, Lily Mountford, Lady Byron, J. R. Upton, Mrs. George Mileham, Mrs. Coombes, Marjorie, Mutual Friend, Loveliness, Lady Hanham, Pride of Madford, Very Good, &c. Mr. J. Simon was the only exhibitor of 24 blooms, viz., twelve incurved and twelve Japs; the former were a bit weak. The best were Lady Isobel, Globe d'Or, Duchess of Fyfe, Mrs. James Murray. Selected as the best incurved: E. Nonin, Madame Darrier, &c. His Japs were generally similar to those staged in the previous class.

Mr. E. Russell, gardener to T. Pirie, Esq., Crayford, was first with twelve bunches of pompons. There were good blooms of W. Sabey, Fremy, Comte de Morny, Rosinante, Rose Trevenna, &c.

Blooms of Japanese arranged with foliage was an attractive feature, and there were classes for Japanese, six blooms of one variety.

A leading feature was the vases containing specimen blooms. In the class for a pair of vases having good blooms well arranged,

Mr. E. Russell, gardener to T. Pirie, Esq., a successful exhibitor in some of the minor classes, was second. With twelve blooms in vases, three in each, Mr. J. Simon was first; there being a good competition.

In the division for single-handed gardeners there were a few classes, but the competition was small. The amateurs, many of whom are workmen in the Royal Arsenal, showed up very much better, and there was a good competition among them. One of the most successful was Mr. C. Symms, of the Laboratory Department; and he again won the handsome Vincent trophy, which is held for one year. Twelve blooms of Chrysanthemums have to be shown, and Mr. Symms won it for the third time for his department, having twelve very good blooms of Japs, chief among them being George Lawrence, selected as the best bloom in the amateurs' division; Madame G. Henry, Mrs. Barkley, M. Louis Remy, Mrs. H. Weeks, W. R. Church, Godfrey's Masterpiece, &c. Generally the display made by amateurs was very good.

There were a few classes for fruit, Apples and Pears preponderating; there were good collections and single dishes of vegetables; and some pretty floral decorations; tables, epergnes, baskets, &c.

Among miscellaneous exhibits Messrs. Wells and Co., Limited, Earlswood, Redhill, had two stands of fine Japs, including Mrs. G. Milcham, Madame Herrewé, Mrs. T. W. Pockett, Madame G. Henry, Miss A. Byron, H. E. Hayman, Nellie Towers, Mrs. A. McKinley, Hon. Mrs. Tennant, Godfrey's Masterpiece, &c. Messrs. G. Bunyard and Co., Maidstone, had a table of dishes of Apples; and Mr. W. J. Minninnick, florist, Woolwich, had some charming floral decorations, showing excellent workmanship.

### Reading and District Gardeners'.

About 120 members assembled at the last fortnightly meeting of the above Association, when Mr. James C. House of Westbury-on-Trym gave a lecture on Sweet Peas. In introducing the subject the lecturer asked the question, "What are the qualities of the Sweet Pea which give it such a high position amongst flowers?" and answered it as follows: The wide range of colour; the softness of its tints; perfume; durability; grace of form; length of flowering season; and that the seed was within the reach of all. Passing on to varieties, he recommended as the best in their various colours: Salopian (crimson), Lord Rosebery (rose and carnine), Prima Donna (pink), Miss Wilmot (salmon), Countess of Aberdeen (blush), Hon. Mrs. Kenyon (yellow), Navy Blue (deep blue), Countess Cadogan (medium blue), Dorothy Tennant (mauve), Duke of Westminster (violet), Black Knight (bronze or maroon), Lady Grisel Hamilton (lavender), Dorothy Eckford (white), Lottie Hutchins (fancy), &c. An interesting discussion followed, in which the president, Messrs. Stanton, Powell, Neve, Hinton, &c., took part. The exhibits were numerous and interesting. Honorary; Mr. G. Stanton (Park Place) made a splendid, as well as an educational, exhibit of a collection of Apples and Pears, consisting of a typical specimen, each correctly named, of fifty varieties of the former and fifty varieties of the latter; also a basket and two pedestals, standing about 2½ ft high, of beautiful specimens of Sweet Peas, illustrating in a remarkable manner the lateness as well as the mildness of the present season. Mr. Barnes of Bear Wood staged three magnificent Melons (not yet named); Mr. J. Pound of Caversham two dishes of Apples, splendid fruits for the season; Mr. Tunbridge, Medmenham, a brace of Cucumbers; whilst for the Cultural Certificate Mr. J. Wicks, the Gardens, Broad Oak, staged six well-grown specimens of Turnford Hall Begonias, and Mr. House of Oakfield Gardens a seedling Chrysanthemum. The Certificate was awarded to the Begonias.

The prizes won in the recent Essay Competition were presented to the successful competitors as follows: Seniors: "All phases of pruning in connection with hardy fruit culture." First prize, value 40s. (mathematical instruments and microscope), Mr. C. P. Cretchley, The Gardens, The Honeys, Twyford. Second prize, 30s. (clock), Mr. G. Hinton, The Gardens, Walmer, Reading. Juniors: "The best means of maintaining a supply of vegetables all the year round." First prize, 30s. (six vols. "Wright's Fruit Growers' Guide"), Mr. W. G. Wadge, The Gardens, Bear Wood. Second prize, 20s. (mathematical instruments), Mr. A. Etherington, The Gardens, Park Place. Four new members were elected.

### "Chemistry of the Farm."

This forms No. 1 of Morton's Handbooks of the Farm, published at 2s. 6d. by Messrs. Vinton and Co., Limited, 9, New Bridge Street, London. The present issue is the fifteenth edition and fourth revision of Professor R. Warington's book, which has been a leading light to farmer and gardener students of this subject for nigh twenty-five years. There are over 250 pages of very explicit and reliable matter, and the price of the book is such as puts it within the means of the youngest apprentice or journeyman gardener.

### Fruit Forcing.

**PEACHES AND NECTARINES: EARLIEST FORCED HOUSE.**—The final thinning of the shoots or branches should have immediate attention, unloosing the trees from the trellis and tying them in convenient bundles so as to admit of ready access to the woodwork and glass for cleansing operations. Wash the glass with water, and the woodwork with carbolic soap and water, using a brush; then wash the trees with a solution of paraffin soft-soap, 4oz to a gallon of water, at a temperature of 135deg, applying the solution with a brush, taking care not to injure or dislocate the buds. If necessary, the dressing may be repeated, adding ½oz sulphide of potassium to the solution, thus combining an insecticide with a fungicide. Limewash the walls. Tie in the trees loosely, allowing space for the growths to swell without binding, letting the young shoots be laid in about 9in asunder, and not closer on the branches than 15 to 18in. A shoot of 12 to 15in length will give a good percentage of fruit for thinning, provided the wood be well ripened, and a Peach worth the name to every foot of trellis covered by the trees is quite as much as those under early forcing can support year after year, though the medium sized Peaches and Nectarines may be allowed only a space 9in square.

Under the most approved methods the trees will have been at rest some time, and the roof lights having been removed, the borders with the recent rains have been well moistened down to the drainage. The house also would be thoroughly cleaned, the trees untied, pruned, dressed with an approved insecticide, rearranged and tied on the trellis, the border surface dressed, and all put in complete order when the leaves were all down, ready for a start when the time arrives. If, however, the roof lights have not been removed, do not allow the soil to become too dry at the roots of the trees, as that is sufficient to cause the buds to fall. If the trees are weakly or with too many buds, a supply of liquid manure whenever water is necessary will be of great benefit. The loose surface soil or mulching also should be removed down to the roots, not disturbing them, but supplying an inch or two thickness of good loam, afterwards sprinkling on it about 4oz per square yard, and pointing in lightly, of a mixture of five parts bonemeal and two parts double sulphate of potash and magnesia (refined kainit), mixed. Borders that are rich in humus from heavy dressings of manure or thick liquid may be dressed with basic slag powder, using about 4oz per square yard and pointing in not so deeply as to disturb the roots. This acts as a corrective of sourness from the lime (about half), and supplies phosphoric acid. Or, dress with freshly slaked lime in about the same proportion of weight, which will be much bulkier dressing, pointing in without disturbing the roots to any great extent, omitting the top-dressing before mentioned. In treating the border it should be practised on both inside and outside borders. Admit air to the fullest possible extent, a little frost not doing any harm to the trees.

**SECOND EARLY HOUSE.**—The trees are now leafless, and should be pruned after unttying. The house ought then to be thoroughly cleansed, with the object of exterminating insects before they have time to find safe quarters. A good syringing with petroleum and water, a wineglass-ful of petroleum to 4 gallons of water, one person syringing into the vessel and another on the house and trees so as to wet every part, is a preliminary step that we have found of value, and it does not leave a film on the glass, as do soapy solutions. In pruning early forced trees it is not advisable to cut away much wood, nor indeed any kind of trees at the winter pruning, confining it to removing any useless parts, and any long, unripe shoots which may be cut back to a triple bud, making sure that one is a wood bud, or to a wood bud on well ripened wood. Shoots, however, need not be shortened under any circumstances except where there is not space for the successional growths, or to originate growths for furnishing the trees. Those of 8in to 12in in length should not be shortened at all, as they usually have wood buds at their base and one at the extremity, the others being blossom buds. It is a mistake to retain much wood, which weakens the trees in flowering, and there is not space for training the young growths without crowding. In other respects treat the trees and borders as advised for the earliest house.

**HOUSES STARTED IN FEBRUARY.**—The trees are shedding their leaves, and the buds are not too highly developed; this is assuring of the trees retaining them, for over-development of buds, combined with dryness at the roots and fluctuations of temperature, with changes of moisture, are the chief causes of the buds being cast. Any lifting or root-pruning yet in arrears

should be seen to and brought to a close as soon as possible. When the leaves are all down it will be an advantage to remove the roof lights and expose the trees to the weather until the time of starting, or till the buds commence swelling. The severest weather will not injure those with ripened wood. Where the roof lights are not moveable admit air freely in all but very severe weather, and even then, if the hot-water pipes can be emptied of the water and kept so, and see that there is not any deficiency of moisture in the borders. If the trees are not lifted remove the surface soil down to the roots, and supply fresh stiff loam, to which has been added some charred refuse, not more than one-tenth, and a sprinkling of bonemeal.—ST. ALBANS.

### Kitchen Garden.

**SPINACH.**—Thinning out the plants may be continued, removing many of those with the largest leaves, the smaller plants wintering better. Take out weeds from among the plants, also between the rows, the soil being loosened with the hoe when dry.

**TURNIPS.**—The growth of Turnips sown in early autumn has been free, and the plants rapidly become crowded, which hinders the swelling of useful roots. The necessary reduction of numbers must be carried out, weeds removed, and the soil lightly stirred among the plants.

**CAULIFLOWERS AND BROCCOLI.**—The heads of these now turning in are liable to be injured by frost. Lift some of the plants and lay in in damp soil in a cool structure, or protect the heads by breaking some large leaves over them.

**ASPARAGUS BEDS.**—The stems of Asparagus have all withered, and should now be cut down. Some growths are full of berries which easily fall, and the result will in another year be a crop of seedling plants. These are not desirable on permanent beds, so it is best to cut off these berried plants first, avoiding scattering the berries on the soil. When the stems have been cleared off, then fork up the weeds and afterwards point up the surface, avoiding injuring the crowns of the plants by going too deep. Follow this by spreading over the whole surface of the beds a mulching of short, decomposed manure, and cover with a layer of clean soil from between the beds. In order to finish off the beds clean and neat, cut down the sides with a spade and leave the intervening spaces level. The manure and soil may remain until spring, when some of it may be removed.

**CELERY.**—Any rows of Celery that remain to be earthed should be dealt with in dry weather, choosing a period when there has been but little rain for several days. Break down the soil and apply it at once to the plants, drawing the leafstalks closely together and working the soil well round each plant. Finish off the ridges in a neat manner.

**BLANCHING ENDIVE.**—Endive is a useful salad on the approach of winter, but needs blanching to make it tender. One of the oldest methods of blanching is tying up the leaves about two-thirds of their way up, so as to well enclose the hearts, and keep away the light from them. It is only desirable to blanch a few plants at a time, the exact number being ascertained by the needs of the establishment. Besides tying up the leaves, there are other methods of blanching. Two boards may be placed lengthwise over the rows, forming a ridge. Under this the plants will be kept dry, and, at the same time, blanch for use. A similar effect may be produced by inverting pots over each plant, the pots being sufficiently large to well cover them. They must be perfectly dry at the time, or decay will set in. When frost and snow is likely to approach, take up plants and place in frames, the roots in damp soil. If a dry, sheltered border under a wall is available some plants may be preserved there, covering with boards, pots, handglasses, further protecting during frost with straw or mats. One of the hardiest Endives is the broad-leaved Batavian. It is less liable to decay, and does not require the special protection that Moss-curbed and some others do. Slates placed over plants will also blanch them.

**LETTUCE.**—All plants, whether full-grown or of seedling size, should be retained as long as possible. The large plants may, if growing out in the open, be lifted and placed in frames, or under the shelter of a wall. The protection needed by Lettuce is not so much preservation from cold as from damp, which causes the leaves to rot at the base. Therefore, if moisture can be prevented being deposited by some covering, and, at the same time, a free circulation of air always ensured, the plants will keep in good condition for some time. Young Lettuces, both of Cos and Cabbage varieties, often winter admirably under walls, especially when they are only of medium size.—EAST KENT.

### A Fruitful Plum Tree.

A Plum tree in the garden of Mr. Jay, of Southgate, London, bore a fine crop of fruit. Before this crop ripened the tree bore a second crop, which matured soon after the first crop was gathered; and Mr. Young, the gardener, has been supplying his master's table with dessert from this crop for several weeks. The tree, which is still in full leaf, has now a third crop of fruit, which has attained the size of green peas.

\* \* All correspondence relating to editorial matters should be directed to "THE EDITOR," 12, Mitre Court Chambers, Fleet Street, London, E.C. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense.

**BLACK CURRANTS AND BUD-MITE (W. M.).**—We should have thought that everyone was aware of the utter impossibility of overcoming such a severe attack as yours is. The plants should be grubbed up, root and stock, and burned. Write to the Board of Agriculture, Whitehall, London, for their pamphlet, which will give you full information and guidance. This can be obtained free of charge.

**PROVIDENT GARDENERS (H. C. W.).**—What we wrote was that the United Horticultural Provident and Benefit Society originated at the Green Dragon Hotel, in Bishopsgate Street, but we should have further stated that the name and present address of the secretary is Mr. Wm. Collins, 9, Martindale Road, Balham, London, S.W., to whom we have forwarded your letter. We thoroughly commend this society.

**EARLY POTATO CULTURE (J. J. G.).**—My employer wishes me to take in hand an experiment with early Potato culture, and, if it succeeds, will go in extensively for it. We will plant one acre from boxes, the same as the Ayrshire farmers do. Can you give me any details? Are the boxes of Potatoes stood in tiers in cattle sheds? About what length are the sprouts when they plant them out? To stand the boxes in tiers means that the growth will be blanched, does it not? Does that matter? What time are the Potatoes put in boxes in the sheds, and what is the usual time for planting? Our field is a sheltered one, on the shore of the Bristol Channel, an ideal field for the purpose. We purpose planting Duke of York Potato. I have taken in the *Journal of Horticulture* for a good many years, and generally look over the page allotted to farm work, hence my reason for thinking your writer on farm work may be able to give me the information I ask for. Trusting I am not trespassing in any way in asking these questions.

[The practice you allude to as Ayrshire is nearly a century old, we having seen it followed over sixty years ago on the alluvial soils of the Ouse Valley. The seed Potatoes are stood on end, eyes upwards, in boxes or trays about 2ft 6in long and 15in wide, and 2in to 2½in deep, a piece of wood being affixed in each corner of the box, about 4½in high, so that when the Potato sets are placed in the boxes these can be placed one upon another, thus allowing space for the sprouting and securing the sprouts of a short, sturdy, and greened nature. The sets are thus set up about the middle of February, and placed in any room, cottagers or small holders having them in the kitchen or other place where frost has not access, this being all that is necessary, hence any outbuilding, or even cow-houses, as you mention, will answer. The great point is not to have them in too warm a place, so as to start the sets into weakly and long sprouts, but have them as stout as possible, and about ½in longer from that to ¾in at planting time. If likely to be too late, the boxes are covered over so as to ensure more warmth and speedier sprouting. This results in blanched sprouting, hence the sets are generally inured to the light, and are kept in a cool place if likely to be too forward, until planting time, always having them well hardened off by keeping in cool quarters, but safe from frost, for a time previous to planting. Planting is usually practised in the third or fourth week in March, the rows being about 20in apart for the first early varieties, such as the Ash-leaf kinds, Sharpe's Victor and Early Puritan, a foot distance being allowed between the sets in the rows. Well rotted manure is placed in the rows, and the sets are covered about 5in deep. The plants are hoed as soon as well up, cleanly culture being very important, and when about 4in high they are earthed or moulded up with hoes, so that the furrows are narrow and the rows broad. The crop is ready to lift by the latter part of June in the district named, and probably would be somewhat earlier in your locality, it possibly being advisable to plant earlier. The great thing is to so plant as to safeguard as much as possible from injury by spring frosts, though oftentimes the tops are cut off, when planting is deferred, to the third or fourth week in March. The varieties named are best for first early crops, and if you work on the plough system of planting and earthing up, the rows must be at least 4in more apart. The variety you name is a second-early, it, Duke of York, and White Beauty of Hebron being good croppers, and would require at least 24in distance from centre to centre of row.]

**NOTICE OF APPOINTMENT (H. N.).**—We make no charge for such announcements in our editorial pages.

**BOOK WANTED (T. W. N.).**—We know of no separate work which treats of rockery-making with artificial cascades. Special information on the subject is contained in the new edition of "The Gardeners' Assistant," and you will also find information in "Cassell's Popular Gardening."

**TRANSPLANTING LARGE ASH TREE (W. J. Hufts.).**—As the Ash has a good fibrous root formation generally, the tree 10ft to the branches, 2ft 8in in circumference, at 3ft from the ground, and with 20ft spread of branches, it is likely to transplant safely, if carefully lifted with a good ball of soil, preserving all the roots and soil attached to them in an area not less than one-third the spread of the branches. It is preferable, however, to take out the trench at half the distance from the stem all round the head has spread of branches, and then work under the roots towards the stem, removing all the soil that does not adhere well to the roots. Then place battens under the ball of the tree, and secure erectly; it can then be removed to its new position. In this it should not be planted deeper than it was before, and being well secured against displacement by wind, we do not see why it should not do well after replanting. As you have been successful with Horse Chestnut trees of similar size, there is nothing to be doubtful about in removing the Ash. It would be best lifted and replanted now.

**CULINARY PEA WITH THREE FLOWERS (F. G. S.).**—I find a Pea among a very late sowing of Veitch's Perfection, which has the peculiar property of carrying three blossoms on nearly every stem, on a shoot 12in long; there are six stems, every one of which carry three blossoms. This would evidently be a valuable one for breeding from, but it is so late, I see no prospect of saving any seed from it; the blossoms all drop unfertilised. The stem is about a yard long, trailing on the ground, and shows no indication of breaking at the base. Can you, or any of your readers, suggest anything likely to result in saving seed? If I could save the plant over the winter I might obtain seed.

[It is unusual for garden Peas to produce three flowers on a stem, especially the variety you name, and not less remarkable that they drop off without setting. Possibly they are devoid of ovaries, or, it may be, of pollen. If not the latter there may be something in it of value for "breeding purposes." We are not aware of the rootstock of a Pea having been kept over winter, as sometimes is done with Scarlet Runner Beans, but you may lift the plant carefully, pot it, and cut off the haulm to within a few inches of the soil, keeping in a cool house during the winter. Whether it would live and push growth from the base we cannot say, but as it has not done so already, we think it hardly likely to do so.]

**NAMES OF PLANTS.**—Correspondents whose queries are unanswered in the present issue are respectfully requested to consult the following number. (Camwell).—*Stanhopea Wardi* var. *aurea*. (Caterham).—*Cupressus Lawsoniana nana*. (D. G., Yorks.).—*Hibiscus*, probably *Cameroni fulgens*. (J. Taylor).—*Funkia ovata*. (J. B.).—A specimen of the Osage Orange, *Maelura aurantiaca*, which we have never figured so far as we remember. 1, *Juniperus virginiana*; 2, *Abies Nordmanniana*; 3, *Juniperus chinensis*; 4, *Arbutus Unedo microphylla*; 5, *Pinus excelsa*; 6, *Tilia argentea*; 7, *Picea alcockiana*; 8, *Ulmus glabra* (Wych Elm); 9, *Larix europaea*; 10, *Larix* sp., leaflets had fallen; 11, *Juniperus chinensis albo-variegata*; 12, *Ceanothus* sp., flowers very much withered.

**NAMES OF FRUITS.**—Correspondents whose queries are unanswered in the present issue are respectfully requested to consult the following number. (M. R.).—1, *Souvenir du Congrès*; 2, *Beurré Charneuse*; 3, Apple, *Crimson Costard*. (X. Z. A.).—1, *Blenheim Orange*; 2, *Cox's Pomona*; 3, *Lane's Prince Albert*. (J. M. W.).—*Pomeroy* of Somerset. (J. M.).—1, *Hollandbury*; 2, *Cox's Pomona*; 3, *Melon Apple*; 4, *Hambleton deux Ans*; 5, *McIndoe's Russet*; 6, *Hawthornden*; 7, *Tibbett's Pearmain*. (W. L. Suffolk).—1, *Emperor Alexander*; 2, *Pott's Seedling*; 3, *Stamford Pippin*; 4, *Bess Pool*; 5, *Gascoigne's Scarlet Seedling*; 6, *Herefordshire Pearmain*.

## Obituary.

David Saunders of Cork.

This gentleman died, after a brief illness, on October 12. He was the senior partner of the old-established firm of Friars Walk Nurseries, Cork. Nurtured from his childhood at the calling of a florist, by his energy, honesty, and enthusiasm he commanded an extensive connection and made many friends. Among all Irish gardeners out of situation he was their "friend in need." For many years he suffered from a weak heart, which at last ended by his passing away from a widow and a numerous family. The business will be conducted as usual, his son settling into his worthy father's position, assisted by his English foreman, Mr. Hawker.

## Meteorological Observations at Chiswick.

Taken in the Royal Horticultural Society's Gardens at Chiswick, height above sea level 24 feet.

Dark misty mornings and dull days have been the prevailing features of the past week, with a few intervals of bright sunshine and slight showers on four days.

## Grievances.

The idea is so old that it has become proverbial, that the English farmer is ever a grumbler. The weather is never right, prices are never right, and his burdens are always heavier than those of his fellow subjects. One of the reasons, we venture to think, why there is so much grumbling among farmers is this. Each man lives in a little world of his own—quite isolated—without any (or few) attempts at co-operation with his brother farmers, and we all know that a burden shared is the easier to bear. We think among grievances the first we must note is that we are so inadequately represented in Parliament. Don't all exclaim at once "We know what you are going to say." The landed interest is fully represented, but the landed interest is not—the tenant farmer. That the interest should be identical we all know, but, alas! we all know that that is not the case. We have working men in Parliament; we have scientific men, we have lawyers, and great traders, but oh! such a lack of the genuine hard-headed tenant farmer.

Why this should be so is partly owing to apathy; partly too, for lack of the sinews of war, and partly because there is an undefined feeling that the candidature of a tenant farmer would not be agreeable to the land-owning section of the community. As we said a week or two back, quoting from

a writer on American agriculture, we only got a special minister when our agriculture was dead. Well, we don't quite think so, and we have not a word to say against our present man, but still it seems to us that it is only by happy chance we have got a good man this time—it is quite probable that at the next change of Government we may get a man with no more knowledge of our requirements than a two-year-old bullock.

It has been dinned into our ears so long that no Government cares twopence for us, that we are beginning to believe the statement, and thus we fail to exert ourselves when an election comes to remedy this state of things. Here the apathy comes in. The evidence that we have been reading lately relating to the malpractices of the remount buyers has not been very pleasant, and not calculated to give us a good opinion of those engaged in the traffic. There has been far too much of the shadiest class of horse-copers at work, and the Government has been defrauded and cheated on all sides. We don't wish for a moment to impugn the characters of those officers who did the work. As honourable men they expected to deal with honourable men, but their very simplicity landed them in difficulties. A few shrewd fox-hunting farmers, examples of which we could pick out in every hunt in England, would have done the work far better, with credit to themselves and at a tithe of the expense to the country. This will all happen again the next time we have a big war—we are so stupid, it takes so many lessons before we arrive at the most simple facts.

We will now touch on a point that affects the meat-eating community. Those who studied the Board of Trade returns as regards agricultural live stock would note with apprehension the diminution of our live stock, and at the same time they will note that their butcher's bills are increasing in an unpleasant manner. It is said by the London Butchers' Society that the rise in meat is equivalent to a reduction in the working man's wages of 2s. per week. The people who will feel the pinch the most are those who have small and unfluctuating salaries. Together with this shortage of home-fed meat we have been obliged to close our ports to live stock from Argentina. Chilled and foreign meat, indeed, does come, but as long as there is the slightest suspicion of disease in that country the law is very plain as to our duty in keeping our ports closed. There may not at this moment be actual disease in Argentina, but Mr. Hanbury points out that the authorities of that country were allowing cattle to be landed on their shores from infected districts, and as long as that is so we must continue to protect ourselves by stringent regulation.

There is another set of good folk who have a grievance just now against Mr. Hanbury. Our Scottish farmers would like to be allowed to import from Canada young stock for the purpose of store. They, like us, complain of a shortage of home-bred stock, and they would fain supply the deficiency from over seas. So far, Mr. Hanbury is obdurate. He is by no means convinced that Canada can show a clean bill of health, and the result, were disease imported (as it easily might be, and has been many and many a time), would be most terribly disastrous.

From beef to milk. It is all this standard business that is causing the bother. Constantly some well-known, highly respectable farmer is being hauled before the justices for defrauding his customers of their proper percentage of fat in the milk. No account is taken of the fact that the morning's milk is always lower in fat than the evening's, and that if both milks were averaged the percentage would always exceed the legal standard. Only last week, in a leading agricultural paper, a farmer stated that inspectors are by no means careful enough in taking their samples for analysis. He instanced his own case, where the portion sent to him on being forwarded to an analyst came out at 6.5 milk fat. He knew himself that must be absolutely wrong, for on taking another sample the result was 3½ per cent. fat, much nearer the point. These sort of things are constantly occurring, and more often the result is adverse to the milk dealer. One is equally as unfair as the other.

Then there is another point which causes much soreness, and really is a great check to legitimate trade. We refer to the regulations respecting swine fever. We believe now the final referees are the members of the County Council, instead of, as in former days, the magistrates of the petty sessional division. Suppose there is an outbreak of swine fever in a certain county division; for the sake of argument we will suppose the outbreak is almost on the boundary line of

another county. The whole county division, be it ever so wide, is declared infected, whereas no difficulty is made respecting that county which is only separated from the infectious place by a few miles, but still out of the county boundary. There is at present an extraordinary scarcity of pigs for either breeding or store, and this will continue to be the case till the restrictions are tempered with a little more common sense.

By all means isolate and quarantine any suspicious cases, but make the cordon quite irrespective of county boundary. There is no magic in the imaginary divisional line. We omitted one little fact about the milk traffic. A dairyman is subject to visits from inspectors, who see that his stock is healthy and his buildings clean. His milk is tested, and he is pulled up sharply for any shortcoming. He must not sell milk if he should, unfortunately, have a case of infectious disease in his house. These regulations are all suitable and good, and we don't quarrel with them; but what we do object to is that milk may be sent to us from abroad—it is received, sold, consumed, and no questions whatever are asked.

Of course, it would be practically impossible to trace that foreign milk to its source, and even then we should have no *locus standi* to interfere; but if we had any say in the matter we would take good care that no foreign milk was put on our markets which did not first pay so big a toll as to make the business practically prohibitive. This sounds vindictive—perhaps it is, but we have still to learn why the gander should not be served with the same sauce as the goose.

One more word and we have done (not that the list is closed by any means). For the week ending October 4 (this year) the import of hops is 9,137 cwts., as against 425 cwts. the same week last year, and yet all these hops are allowed to be landed without tariff, or any restriction or regulation as to where grown and when, and other particulars which English growers are obliged to furnish or are subjected to pains and penalties. Is this right? We make bondmen of the home born and extend the freedom of breweries to every outsider. Verily this is Free Trade with a vengeance.

### Work on the Home Farm.

We have had a fine week, have practically finished Potato getting, and are now able to do something like a systematic threshing. Previously there was neither time nor suitable weather for the job, and when half a dozen neighbours are waiting for the machine it would be selfish to keep it long, so we have pushed on with the other work after threshing just enough straw for pressing needs. Now we have got the machine back, and are dipping deeply into the Barley stacks. So far the result is not unsatisfactory. The yield is fairly good, and there is less tail corn than was expected. The colour is fair, and much improved in the stack; it will be better still for a little longer sweat in the other stacks. Price is disappointing for good-class Barley. It should realise more than 28s. per quarter. The markets have been very slow owing to so much corn coming in out of condition, but there are signs of a better demand for the well got samples. There is certainly more inquiry. We ought to be thankful for having got our corn so well, and to be selling fair crops at 28s. for from information just received there is much grain still out on the high wolds of Yorkshire and Lincolnshire. One farmer in the latter county had 500 acres still in the fields a few days ago.

We have noticed a drill at work, and shall be using ours to put the ley Wheat in at once. The Potato land must be ploughed, and then it will be ready to follow on with. We shall sow 12 pecks of seed after ley, as the season is late, but only 10 pecks after Potatoes. Though it has been fine overhead, Potato gathering has been dirty work lately, and much soil has gone into the pies. A neighbour who got some Potatoes up one day and sent them to London the next, has quickly had a letter from his customer there reminding him that he has bought his Potatoes, not the soil of his farm. Those Potatoes were sorted by hand. If a riddle had been used there could have been no complaint.

The sheep are beginning to take well to Turnips, and now that we can spare an extra hand, the roots will all be cut for them. On the portions which they have grazed there will be some waste, as the hogs do not clean up the shells and the ewes are not ready to do it for them.

We fancy that unripe Turnips may have caused some of the losses amongst lambs (we, perhaps, should say hogs), whose delicate stomachs never could stand very green Turnip tops. If the tops are trimmed off a couple of days before use there is no danger.

The pigs are rejoicing in plenty of steamed Potatoes, and are doing well. The harrowings, as they are picked off the land, make grand pig feed. Sound Potatoes are cheaper than diseased ones for pig food even if they cost double the price.

## BARRS' GOLD MEDAL DAFFODILS

Have received Twelve Highest Awards, 1902, including **TWO GOLD MEDALS**  
Descriptive Catalogue of all the finest sorts in cultivation free.

## BARRS' GOLD MEDAL TULIPS

Have received **FIVE GOLD MEDALS** from the Royal National Tulip Society; **SILVER CUPS** at the Great Temple Flower Shows, 1900 and 1901, and **GOLD MEDAL** 1902.

Descriptive Catalogue of the finest kinds for pot culture and for forcing, and for beds and borders outdoors, free.

|---------------------------------|-----|
| 12 fine and lovely varieties .. | 5/- |
|---------------------------------|-----|

**CLIBRANS free-flowering HELIANTHUS**, the most conspicuous of all late summer and autumn blooming plants.

|                                      |     |
|--------------------------------------|-----|
| 6 distinct and selected varieties .. | 2/- |
|--------------------------------------|-----|

**CLIBRANS JAPAN IRIS**, grand, gorgeous, and beautiful.

|                                    |      |
|------------------------------------|------|
| 6 lovely and charming varieties .. | 6/-  |
| 12 ..                              | 10/6 |

**CLIBRANS GERMAN IRIS**, easily grown, free flowering, and highly ornamental.

|                                   |     |
|-----------------------------------|-----|
| 12 choice and select varieties .. | 4/6 |
|-----------------------------------|-----|

**CLIBRANS choicest PHLOX**, for beauty and effectiveness, combined with freedom of flowering and ease of culture, it would be difficult to surpass.

|   |      |
|---|------|
| Plants 1 year old, 12 choice varieties .. | 3/6  |
| " " " 24 ..                               | 6/6  |
| " " " 50 ..                               | 17/6 |

**CLIBRANS DOUBLE PÆONIES**, varying in colour from white to deep crimson.

|                        |                           |
|------------------------|---------------------------|
| 12 choice varieties .. | 9/-, 12/-, 15/-, and 18/- |
|------------------------|---------------------------|

**CLIBRANS SINGLE PÆONIES**, extremely beautiful, and possessed of as wide a range of colour as the double varieties.

Unnamed varieties to colour .. 20/- per dozen

**CLIBRANS POTENTILLAS**, easily grown, and effective plants in a moderately rich soil.

|                                 |     |
|---------------------------------|-----|
| 12 double-flowered varieties .. | 4/6 |
| 12 single ..                    | 3/6 |

**CLIBRANS selected PYRETHRUMS**, excellent subjects for producing an abundance of flowers.

|                                 |     |
|---------------------------------|-----|
| 12 double-flowered varieties .. | 4/- |
| 12 single ..                    | 4/- |

**CLIBRANS selected SAXIFRAGAS**, invaluable in early spring and throughout the summer.

|                                   |     |
|-----------------------------------|-----|
| 12 distinct and fine varieties .. | 3/6 |
|-----------------------------------|-----|

**CLIBRANS beautiful TROLLIUS**, easily grown and very showy plants.

|                     |     |
|---------------------|-----|
| 4 fine varieties .. | 2/- |
|---------------------|-----|

**CLIBRANS lovely VERONICAS**, a pleasing and charming family of plants, in which the prevailing colour is blue.

|                       |     |
|-----------------------|-----|
| 9 pretty varieties .. | 3/- |

THURSDAY, NOVEMBER 13, 1902.

### Light, and Plants.

**B**EING fully aware of the importance of light in the growth of plants, one would think that the gardener would make it one of his first duties to become thoroughly conversant with all its properties. But it seems to be generally classed amongst those simple things that are too simple to need investigation. The study of light is most certainly the reverse of being simple, as throughout the entire course of physics there is no section more difficult to fathom—or more fascinating to read—than optics. It is by the analysis of light that we have become acquainted with the composition of other worlds and their surrounding atmospheres, and by a similar process some of the most complex compounds are accurately analysed, even though some of the component parts are extremely small in quantity. However, it is not to discuss the uses of spectral analysis that I make these notes, as they are made with the hope of impressing on those gardeners who are not conversant with elementary optics the importance of the study of light in plant growing.

Every luminous body emits its own peculiar light, but it is only with that light known under the name of daylight that I have to deal. We will take it in its simplest form—that of a ray of sunlight—and will at once analyse it. The result will be that the pure, colourless light from the sun will be found to be a magnificent compound light consisting of the following colours: violet, indigo, blue, green, yellow, orange, and red. To break up a ray of sunlight in this way is extremely simple, as all that is required is a triangular glass prism and a dark room. A small hole should be made to emit the sun ray, and the prism should be fixed in such a

**R**EADERS are requested to send notices of Gardening Appointments or Notes of Horticultural Interest, intimations of Meetings, Queries, and all Articles for Publication, officially to "THE EDITOR," at 12, Mitre Court Chambers, Fleet Street, London, E.C., and to no other person and to no other address.

way that the ray falls on to it. If a screen is placed at some distance behind the prism it will be found that the ray, on emerging from the other side, will cast on to the screen, not a ray of clear light, but a band of the seven distinct colours named above, and in the same order, the violet being at the top. If one wishes to carry the experiment further they may again collect these rays and combine them as a clear ray again. This is done by arranging seven small mirrors on stands in such a way as each one reflects a band of the decomposed ray or spectrum, and then making the reflections all converge on one spot. Every object, unless it be black, reflects one or more of these colours, and absorbs the remainder. In the case of a green leaf, the violet, indigo, blue, yellow, orange, and red are absorbed by the leaf, and the green alone reflected. Thus, an object has no real colour, but only reflects a certain colour or colours. This may seem a strange truth to many, but it can easily be proved, as if the light is deprived of its green, the leaf no longer appears green, but is colourless or black.

To test this fact, a green plant may be stood in a room lit by a pure yellow light, when it will be seen that all the colours will be cut off, with the exception of the yellow, and all objects in the room not naturally reflecting a yellow shade will be black. In order that a plant may perform all its functions properly it must have the whole of the colours found in a sun ray, and to have any of them shut out is to have a marked effect on the condition of the plant. Those of an experimental turn of mind may care to take the trouble to grow plants under coloured glass and note the results.

For the benefit of those who have not the time to investigate the matter, I may say that under the effects of the colours of the red end of the spectrum the growth will be long and sappy, while the colours of the blue end encourage a very stunted growth. One often sees the green shading used. I am of opinion that this is one of the most unsuitable of colours, and I think my theory is well based and well supported, for most plants absorb all the colours but green, and if they reflect, and, therefore, when shaded with green all the essential colours are cut off, and only the rays that most plants refuse to absorb are allowed to pass. Under the influence of coloured light the functions of a plant soon lose their proper balance, and are thus prone to disease and an easy prey to insects. The sooty deposits on glass in the neighbourhood of towns have a very marked effect on plants, as, starting out as they do, many of the rays of the violet end of the spectrum, the growth is out of proportion owing to improper assimilation, and the leaves and stems very soon become excessively drawn and sappy if the conditions are allowed to continue. The gardener here has the remedy in his own hands; but in the case of a smoke fog he is powerless, as the smoke in the atmosphere cuts off almost all other rays but red, yellow, and orange, and thus overthrows the balance of Nature, and makes plants doubly sensitive to the chemical action of the smoky matter on their tissues.—J. G. COLE.

## Economy.

(Concluded from page 396.)

### The Up-keep Bill.

We—gardeners—have a grievance; no fanciful, ghostly thing, but a real, tangible grievance, when from economical or other considerations a loosely formed estimate of supplies is made to cover the gross total of expense. Whether it is the methods of modern living, or whether it is something else, which causes a falsely frugal sentiment to prevail it matters not; prevail it does, and that, too, in places where one would least expect to find it, for millions of money form no barrier to the *bête noir*. Bred, probably, in some poverty stricken garden, it spreads as rapidly as the Potato blight, until it reaches the rich man's table at such time as dinner parties are in vogue, and then, like a bolt from the blue, all sorts of questions are sprung, and very disagreeable ones, too, unless the man most concerned is prepared for a contingency which may arise at any moment. There is the visitor ironically known as "The gardener's friend" who flits from place to place, regarded by the visitors as an authority upon all matters horticultural; and the gardener, if wise in his own generation, sacrifices on the altar of hyper-criticism peace offerings of the best of his produce during the visit, all of which receive due meed of

praise, with the qualification that the Grapes, Melon, or Pine were rather better finished, higher in flavour, or slightly larger at the last place visited, amounting in the aggregate to "That faint praise which——" The gardener's friend is very well known to them, and rightly credited with making things uncomfortably hot; and once the ball is set rolling it gathers momentum that may take a mountain of hard facts to stop it. However, it sometimes rebounds from the last visiting place ahead, or "ahint," the sufferer being solaced by hearing that *his* produce was "rather better finished, a little higher in flavour, or slightly larger." Now and again, unfortunately but rarely, it ricochets to its manufactory, the dinner table, when, if all such opinions are not knocked on the head, the sting, at least, is extracted from the tale. Prior to the visit of a gardener's friend to one particular place the noble host was wont to smilingly say, "Quiz, your friend is paying us a visit; beware." Familiarity with that friend's (?) gardening opinions had at last bred the contempt they deserved from the master as they had at first from the man.

All of this is, of course, a little aside of our subject, but in direct relation to the disagreeable analysis another one makes of the cost of production. But recently a "rattling" bunch of Hamburgs, fully 5lb in weight, was dished up because Mr. So-and-so was coming to dinner; and very fine it was, although the grower says it. "What do you think of that, So-and-so?" said "His Honour," as he lifted the bunch by the nice little bit of nut-brown wood attached to show its proportions. "Ah! very fine, very fine; but look at what it cost you to grow it: all the firing, and all the men you have to keep; you could buy it cheaper." At first sight that bunch of Grapes cost a good deal, and from that view, which is nothing short of a moral squint, employers are apt to frame their estimates. It takes the second sight of a gardener to furnish the addenda which puts the matter in a totally different light; for that second sight sees the vineries now being prepared for the great Chrysanthemum crop, to be followed by a heavy batch of bedding plants, which are no sooner cleared than the temporary tables are filled with Maidenhair Ferns, and every inch of spare space utilised for something else. So, in the cost of production, there are many factors to be taken into the account; and under this head most men are able to show a very good balance to their credit, in spite of being further handicapped by the time, taste, and thought expended in keeping the houses clean and dressy—in fact, in that state suited to a gentleman's or nobleman's establishment. Under these conditions, which most employers look for and all gardeners invariably desire to have, it is, to say the least, unfair to draw comparisons concerning the cost of production between private and market growers, for between the two there is a great gulf fixed, which all the subtlety of logic educated people bring to bear upon it, and which, alas! gardeners are so deficient in, can never bridge over.

Important as is this phase of the matter, it is small compared with the general up-keep of an entire garden comprising the kept grounds and all pertaining to it—wherever, indeed, the gardener's foot goes and whatever his hand touches. Moreover, there are many moderate-sized places, and very good places too, in which frequent calls are made upon the gardener and his men for work wholly extraneous to their immediate sphere of labour. Probably most gardeners know all about this—at the time—and there are very good reasons for men to keep that knowledge in black and white ready for use in their hour of need. A diary of daily doings is a simple matter, but a safe one; and when a man is not able to speak for himself that will speak volumes for him. If weekly returns of produce supplied with its market value attached can be kept so much the better, and with an annual report and balance-sheet showing all these items on the credit side against the sum total of expenditure, the gardener will invariably be found to come out very well. Even cut flowers and furnishing plants alone form no inconsiderable item in many places. Needless to say that a honest, impartial report must be shown, for the value of all statistics depends upon their accuracy. Perhaps such reports and balance-sheets may never be wanted; if so, they need never be ostentatiously paraded, but rest quiescent on the shelf as a more powerful weapon of defence than all vague logic weakened by bad memory could ever be. In conclusion, some may ask what new lines under the head of up-keep have been thrown out for a struggling man to grasp wherewith he can further accomplish the desideratum of saving something without sacrificing to that hateful god, poverty? Men so situated may be able to say, honestly, they are already doing their utmost to give a maximum return at a minimum of expense, and that they can do no more. That is so; neither can—Quiz.

### Laburnum Flowers from Co. Dublin.

Mr. G. Carroth, gardener at Sutton House, Sutton, Co. Dublin, sends a number of Laburnum shoots clustered with flowers, and a letter as follows: "Enclosed please find sprays of Laburnum. The tree is in full flower for the second time this year, and is growing in the shrubbery in the elevated pleasure grounds of Andrew Jameson, Esq., D.L.; overlooking Dublin Bay. These gardens have a south-westerly aspect. This note may be of interest to the readers of your Journal." [In August we saw a Laburnum in flower at Edinburgh.—ED.]

### Cypripedium × Transvaal superbum.

Messrs. Sander and Sons, of St. Albans, exhibited a specimen of this hybrid before the Orchid Committee of the Royal Horticultural Society at the meeting of November 4th, and were accorded an Award of Merit. The parentage is *C. Chamberlainianum* and *C. Rothschildianum*, the former being very apparent in the long curled petals, as shown in Mr. G. Shayer's drawing below. "The upper sepals are pale green, heavily striped with chocolate colour; petals long and extended, pale green, spotted with dark purple; lip rose-coloured with yellow upper margin." It is a very attractive and distinct hybrid.

### The Week's Cultural Notes.

In most collections there are a few plants newly imported, and as a rule these do not settle down to their proper routine the first season. In consequence they require a little special attention. Some may not have finished their growth by the usual time, and these should be encouraged by rather more warmth than the species usually needs. Others may be too forward and in danger of starting secondary growths, and here, of course, the point will be to keep them dormant if it can be done by reasonable treatment; if not, to nurse the growth, so to speak, during the winter; not to hurry it, and allow the bulbs to finish in spring.

As a general rule, however, plants newly imported require, for the first year at least, more warmth than established specimens, and a kind of convalescent treatment to inure them to the altered conditions, and revive them after the trying journey from their habitat to the Orchid house. The early spring is, of course, the best time to obtain specimens newly imported, as they have then the summer to recoup themselves, but they are not always obtainable just when needed, and we have to make the best of them when they do come.

Cattleyas and *Lælias*, for instance, imported during the summer, are now, as a rule, beginning to root, and must have a little material to run in if simply potted in crocks, as they should be. An amount of care is necessary here; the least touch will rub the spongioles off, and even if it does not break the brittle roots, and once checked in any way it will die back to the stem. My plan in such cases is to have ready a few clean damp sphagnum points, and to lay these very carefully over the roots and between them; then to fill up with the Orchid mixture lightly, as, of course, the plants will previously have been firmed in the pots by stakes and ties.

The Belgian leaf soil, now extensively used for Orchids, is very useful in a case of this kind. Having a little rough moss over the drainage crocks the leaf soil may be simply sprinkled over the roots and filled in as usual, no dibber or other tool being needed, and consequently no damage caused to the roots. In either case water must be very sparingly applied afterwards, the roots at first being easily damaged by an over-supply. This precaution is not so necessary in the case of *Cypripediums*, the roots of these Orchids being more able to take up moisture in plenty.—H. R. R.

### Carnation, Duchess of Portland.

This new tree variety, which received an Award of Merit at the latest Drill Hall meeting of the Royal Horticultural Society, was alone staged by Messrs. Cutbush and Sons, of Highgate. Mr. W. J. Godfrey, of Exmouth, was wrongly mentioned as also receiving the Award for this Carnation.

## The Absence of Frost.

The year 1902 has afforded much that is not usual in its weather, almost, too, from its earliest inception, and at the time of writing there are conditions which certainly are not common in November. Summer flowers are still with us, and, it may be said, not in niggardly quantity or variety. Sweet Peas have been gathered in quantity in the first week of November, and should the present mild weather continue there will be other bounteous gatherings of these favourite summer flowers. Roses have been particularly good this autumn, so have Pentstemons from seeds. Dahlias are as free now as at any period of the summer or autumn in some gardens; *Phlox Drummondii*, *Mignonette*, *Marguerite* Carnations, and outdoor *Chrysanthemums* are still blooming quite freely.

This lateness of flower and crop may be adjudged a partial compensation for the blighting influence of the spring and early summer. Late Peas, French and Runner Beans, Cauliflowers, and tender-hearted Lettuce are crops that still give a supply, and for which there is much to be thankful for at this late period of the year. What is most to be dreaded is that should a change of weather bring sharp frosts, vegetation, so full of life and progress, will be hardly dealt with, for it is common knowledge that vegetables in free growth, following a mild period, are sometimes hopelessly ruined with one or two nights' frost.

Magnificent pictures are everywhere seen in the distant landscape. Beeches in particular being intensely bright. The prolonged period of tree leaf makes the removal and sale of young nursery stock scarcely so assuring as would be the case where maturity was more forward. Young trees now assume a luxuriance of the summer, and to dig them up and despatch to distant customers will need more than usual care, with a view to their satisfactory re-establishment and growth another year. This would apply to Apples and Pears more than to stone fruits. These

latter are now active in root-growth, which may be seen on lifting home-grown trees for replanting. There is no inconvenience attending the removal of young trees in the home garden in leaf for immediate planting.

because a ball of soil attached to the roots greatly facilitates progress in their new station, and the newly-formed autumn roots, with the aid of the water pot, proceed almost without a check.

Not quite so when they have to be despatched by rail. When Nature supplies its expectant touch of winter, the leaves of trees respond quickly by their fall, and

fruit growers then look upon their state as a correct one. A few hours is sufficient sometimes to change a leafy and, to the ordinary observer, an unconditioned tree into that of a full-ripe specimen when sharp frost lays its icy breath upon them, followed by a cloudless sunray which plays its part later in the morning.

Some of the latest Pears and Apples are still awaiting their turn for removal to the fruit store, for it has been so often found that, gathered too soon, they have a small value when their natural season for use comes round. Late storing is the remedy for plump Apples in March and April, and in the case of open-air bush or pyramid trees they have been exceptionally favoured this autumn. In the effort to do justice to late sorts we have sometimes seen crops hopelessly spoilt by an unexpectedly sharp frost.

To northern readers this immunity may not be a familiar experience. In Scotland, at any rate, records point to frost of somewhat severe degree. In Wiltshire there has been in some places frost enough to destroy Beans, Marrows, and Dahlias, as well as other plants of tender nature, so much depending on the elevation of the ground. The autumn has been one that clearly points out the colder spots of the garden, judged by the influence of the frost on the tenderest leaf and flower. Such experience may be helpful for future planting, and is one not always so accurately gauged as in the autumn now fast merging into winter.—W. S., Rood Ashton.

[A contribution of magnificent Durendean Pears accompanied the foregoing notes. Heavier or better fruits, or of more beautiful colouring, could not be desired.—Ed.]

Cypripedium × Transvaal superbum.

### Roses in Pots.

For supplying cut flowers during winter and spring pot Roses are, I think, to be preferred to those planted out, because the supply can be regularly maintained by introducing batches into heat at intervals. Another advantage is that in April or May the plants can be placed in the open air, and the houses used for other purposes throughout the summer and autumn. Of course, I have nothing to say against planting out to cover a conservatory roof or the back wall of any other house, but to have a house planted entirely with Roses seems to me to be a waste of space, as it is easy to get an abundant supply of flowers from the open air during the summer months.

A variety of practices are adopted in regard to the time of potting Roses. The most usual course, perhaps, is to pot in June, before the plants are plunged in the open air. This plan answers admirably if the roots are pretty active and the soil well permeated with them; but if they are inactive, and the bulk of the soil drops away, the plants experience a great check, as there is usually some top growth going on. In all such instances I prefer to pot the plants during the autumn, and, indeed, that time answers well, no matter what the condition of the plants may be. Some cultivators do not repot until they have pruned, and are about to place their Roses under glass; but as top growth then commences before roots have pushed into the fresh soil, the best results are not often obtained under that system.

At the present time it is usual to heap plenty of ashes over the surface of the pots to prevent injury by frost. Before this is done I advise overhauling the whole collection, and repotting those which require it. When this is done white, active, young roots will generally be emitted at once; then if some of the plants are pruned and taken into heat early in January they will be in the right condition to start away strongly. From that time onward additional batches should be taken under glass every three or four weeks.

A simple compost answers well for potting. Here is one which I have found perfectly satisfactory. Three parts good loam with plenty of fibre (if stiff rather than light, so much the better), one part old cow manure passed through a sieve, or a similar quantity of fresh horse droppings. To a bushel of this compost add a five-inch potful of bonemeal, and half that quantity of soot. Use the soil in a fairly dry state, and pot firmly.

Those who require large quantities of Roses during April and May next may get highly satisfactory results from strong, young dwarfs lifted from the open ground at once and potted. Plants so treated must, of course, not be forced, but brought on gradually in an ordinary greenhouse temperature.

In the case of all Roses in pots I believe in hard pruning. First cut any old and very weak shoots, then shorten the remaining ones to within a couple of buds of their base, except in the case of a young shoot which is to take the place of a branch which has been removed, such a shoot, if necessary, being left to from 6in to 9in in length. The only difference I make in pruning Teas is to leave a little extra length on the strong shoots, cutting the weak and old ones completely away. This treatment, of course, applies only to those grown in pots. To get good flowers it is then necessary to confine the growth to a few buds on each shoot, because the plant has only a very limited amount of root room.—H. D.

### Seasonable Treatment.

Much of the young stock should now be in a vigorous state of growth. Give air and hereby obtain a healthy, hard growth, which will ward off mildew to a great extent. Of course, judgment should be used as regards ventilating. As a general thing the temperature should not be allowed to go above 72deg to 74deg on Bride, Bridesmaid and Golden Gate, but occasionally we have a day which is very windy, with the sun shining brightly. On such a day as this it is better to allow the temperature to rise

a little than to ventilate fully and thereby cause a strong draught. It pays to have a house under the care of a careful and observing man. Such a man will be able to help the stock in such cases. Although a thermometer is a safe guide in regard to heat and cold, we are sometimes obliged to vary from it when we see that our plants are in need of a little different treatment. For Bride, Bridesmaid and Golden Gate, each largely grown by marketmen, 58deg to 60deg is the proper night temperature, allowing it to rise to 70deg during bright days, when you can ventilate freely.

For Liberty I should advise no lower than 62deg at night. Of course this necessitates growing this Rose otherwise than in a house with Bride, Bridesmaid or Golden Gate. If grown with these varieties it is very liable to go dormant and prove a failure. For a day temperature 75deg is sufficient. This Rose has proved itself to be a stubborn one to force, and it is doubtful if it is a paying variety.

Messrs. Rochford and Sons, of Turnford Hall, grow large quantities of it, and speak highly in its praise.

During the dark days the temperature and the watering should have the very best of attention, such attention as only a careful and observing man can give. When syringing is done frequently, the top of the soil is liable to appear moist, while that near the bottom of the bench is too dry to promote healthy growth. A careful grower tests the soil often by digging down here and there through the house, so that he may know the exact condition of the soil around the roots. Syringe only on bright days, unless there is spider in the house, and in order to keep this pest in check direct the stream upwards, so it will strike the leaves from underneath, as this is where the spider does its work.

The first few crops to be cut are liable to come so that we cut quite heavily for a short time, and then there is a check and a period during which the cut is very light. It is at such a time as this that a careful waterer will aid the plants. During the time the crop is on, the plants will use a liberal amount of water; but after the crop is cut off be careful not to water as heavily, as they do not require it.

## Figs Under Glass.

### Early Forced Trees in Pots.

Where these have been placed in the open air they should be taken under cover without delay, as it is advisable to prevent the soil being soddened by the autumn rains. If the trees have not been top-dressed or repotted, or had the drainage rectified, this must be attended to without delay; the trees should then be placed in a dry, well ventilated, and cool house. Any thinning or cutting back of attenuated branches to give place for promising successional shoots must be attended to, and the trees washed with a solution of paraffin emulsion, one part in ten parts water, adding  $\frac{1}{2}$ oz sulphide of potassium, using a somewhat stiff brush at an angle, so as to dislodge scale if present.

To secure ripe Figs in April and May a well-heated and ventilated house is necessary, and is better with a pit or pits to hold fermenting materials. The pots should be supported on loose brick pillars at the proper height, and the fermenting materials brought up about the pots. The trees then root into the fermenting materials, and derive a considerable amount of nourishment therefrom; besides, they can be fed to any extent, and the trees be in comparatively small pots for their size and crop. Early Violet and St. John's may be grown for affording dishes of very early fruit, but Brown Turkey is the best for general purposes.

### Early Forced Planted-out Fig Trees.

The trees must now be unloosed from the trellis and pruned; those with the roots restricted to small borders, which are the most satisfactory in results, will require the shoots thinned where too crowded, cutting away the growths that have reached the extremity of the trellis and are not longer capable of producing fruit. Cut back to where the succeeding shoots start from the main branches, and remove old, bare limbs wherever practicable in favour of young and promising growths. Remove any elongated spurs, reserving such as are short-jointed and promise for fruit. The house should then be thoroughly cleaned, washing the woodwork with hot water, soap, and a brush, and the walls with limewash. Wash the trees with warm, soapy water, and afterwards dress with an insecticide; then secure the trees to the trellis, allowing room for the growth of the branches. Fork the border over very lightly, not injuring the roots in any way; remove the loose surface material, supply 1in or 2in thickness of good calcareous loam, or add a sixth of old mortar rubbish to good loam; then, or before growth takes place, add 1in thickness of well sweetened manure, and this will tend to keep the roots active near the surface and supply considerable nutrient matter. Ventilate the house freely at all times, excepting during severe weather, when a few degrees of frost will not injure the trees, provided the wood is thoroughly ripe and the soil only moderately moist.—GROWER.

## Old-time Gardening.

(Continued from page 239.)

### Gerarde and "The Herball."

Not by any means is a great deal known of Gerard. He was born at Nantwich, in Cheshire, in 1545, and died in London in 1611-1612, where he was buried on February 18 of that year. Of his parentage nothing is known, nor, though he was married, has any trace of his having left a family been discovered. He himself admits that his education was deficient, yet he attained to a very high position among his fellows, mainly, no doubt, on account of a plodding disposition, and a certain amount of "push," that led him on to undertakings that better qualified men allowed to pass. It is not at all unlikely that his qualifications as a surgeon were less conspicuous than his knowledge of herbs, which contemporaries admit was very great.

He was, however, apt to be imposed upon, even in the matter of plants, and more than one instance occurs in his "Herball" of, to say the least, a lack of acuteness and a facility to admit of deception that detracts somewhat from his character. I should imagine that his greatest forte would be as a gardener. We find him in 1577 established as gardener to Lord Burleigh, and he also possessed a garden of his own, which he calls a "little plot." In his own words, he claimed to "have added from forreine places all the varietie of herbes and floures that I might any way obtaine." Moreover, he challenged inspection of these gardens to afford a proof of his skill as a horticulturist.

In 1604 he rented two acres of ground from Queen Anne, for which he was to pay 1d. quarterly, and in the lease he is termed "Surgeon and Herbalist to the King;" but he held this garden only a year. However, the above affords an indication as to how he had prospered. Another means of forming an opinion as to his position may be derived from the people he knew and corresponded with. For example, he is found in the company of the Lord Mayor, "looking for springs." Lord Edward Zouch, Lete, a leading London merchant, Robin of Paris, Sir F. Crispe, and Lord Wotton are a few among many of the people with whom he claimed an acquaintance.

Gerarde's first literary undertaking was a catalogue of the trees, shrubs, and plants cultivated in his garden. These were 1,039 in number. The British Museum holds this, the earliest "hortus," but in 1876 Mr. Jackson issued 100 copies, with many notes and English names of the plants. This work, too, is now scarce. Gerarde's Catalogue appeared first in 1596, and again in 1599. Meanwhile, in 1597, "The Herball, or Historie of Plants" was issued from the press. This is admittedly the work of a Dr. Priest, who translated into English the *Pemptades* of Dodoens. After the death of Priest the manuscript fell into the hands of Gerarde, who made use of it without, however, stating to whom he was indebted, a practice not uncommon in those days. Material from other authors was incorporated, and not a little was added by Gerarde himself. If not the most trustworthy, it includes, at least, the most interesting portions of the work, the garrulous old fellow chatting away *con amore* as if all his readers were his most intimate friends. Local references are of much interest, and villages, long ago absorbed into the great metropolis, afforded in their several vicinities happy hunting grounds to the ardent botanist, adding, as he did, several plants, not hitherto noted, to the British flora. It is, however, to be regretted that he allowed himself to be deceived—some think he practised deception himself—as in the case of the *Pæony*, which he records as growing near Bristol, the red Rose in a field in Cheshire, and, to crown all that, he himself had seen young Barnacle geese as plants, growing on a plank of wood!

But against these absurdities there is a vast mass of material absolutely novel, and, withal, worthy of all credence. From his remarks on the Potato it would almost

appear that he secured roots from Virginia by Lane's expedition, and these he cultivated. He also tried to cultivate Cotton from seeds, but unsuccessfully, though it "did grow verie frankly." At the time "The Herball" was passing through the press, "Master Nicholas Lete" had sown several pounds of seeds, but Gerarde seems, from his own experience, to have been sceptical of the Cotton plant flowering in England. Then, from the gardener's point of view, Gerarde did an immense benefit in directing attention to the new bulbous plants which were emanating from Constantinople and other eastern parts. Of these mention may be made of the Tulip in variety, various *Liliums*, *Narcissus*, Crown Imperials, and *Fritillaries*. Then, shrubs may be said to have been unknown till Gerarde directed attention to them. He cultivated, among others, *Cercis siliquastrum*, *Ceratonia siliqua*, *Bupleurum fruticosum*, *Viburnum Tinus*, *Syringa vulgaris*, *Sambucus racemosus*, *Spartium junceum*, and *Colutea racemosus*.

*Staphylea colchica* seems to have been somewhat of a rarity, as he mentions the places it was to be found—viz., "at the house of Sir Walter Culpepper, neere Flimwell, in the Weild of Kent, as also in the Frieryard without Saint Paule's Gate in Stamford, and about Spalding Abbey, and in the garden of the Right Honourable the Lord Treasurer, my very good Lord and Master, and by his house in the Strand. It groweth also in my garden, and in the garden hedges of Sir Francis Carew, neere Croydon, seven miles from London." He goes on to say: "It is called in English S. Anthonies nuts, Wild Pistacia, or Bladder nuts; the Frenchmen call it *Baguenaudes* a *patrie nostres*, for that the Friers do use to make beads of the nuts." Then, referring to the commoner fruits, we discover that he cultivated several kinds of Peaches, of which the "yellow" was considered that possessed of the finest flavour, that Apricots grew in his own and "many other gentlemen's gardens throughout all England." Of Pears and Apples he declared (and also of Plums) that each would require a separate volume.

In connection with Pears, reference is made to specialists, where he says: "All these—specified and many sorts more—are growing in the ground of Master Richard Pointer, a cunning and most curious graffer of all manner of rare fruits, dwelling in a small village neere London, called Twicknam." "Mr. Henry Banbury, of Touthill Street, neere Westminster," is also mentioned as an "excellent graffer and painfull planter." From these examples, taken quite at random, it will be seen that Gerarde is an author of many fancies, with whom a pleasant half-hour can be spent very pleasantly.

"The Herball" was "very much enlarged and amended by Thomas Johnston, Citizen and Apothecary of London," in the year 1633, a reprint following in 1636. The new editor was very hard on poor Gerarde, as well on account of his mistakes as because he had been so little straightforward as not to acknowledge to whom he was indebted for the major portion of the material of which his book was composed. Of Johnston's work, as a whole, it may be said that it was largely an endeavour to bring Gerarde's original work up to date.

Following as it did closely after Parkinson's "*Paradisus*," a book like that under discussion, a masterpiece of its kind, it would most likely hardly have been heard of, but for the man whom Johnston pilloried. A specimen of the latter's style is here given, taken from the chapter on Tulips. He says: "I do verily thinke that these are the Lillies of the field mentioned by our Saviour (Mat. vi. 28, 29), for he saith 'That Solomon in all his royaltie was not arayed like one of these.' The reasons that induce me to thinke thus are these: First, their shape, for their floures resemble Lillies, and in these places, whereas our Saviour was conversant they grow wilde in the fields. Secondly, the infinite varieties of colour, which is to be found more in this than any other sort of floure; and, thirdly, the wondrous beautie and mixture of these floures." Johnston was the authority from whom subsequent writers procured the erroneous date of Gerarde's death—"about 1607"—instead of the date given at the beginning of these notes. The correction first appeared over the signature "G" in this Journal in the number for February 18, 1875, in an article of the greatest interest on Gerarde.—B.

(To be concluded.)

### New Japanese Varieties.

The Japanese section of Chrysanthemums increases so fastly in variety that a yearly addition must be made even to the smallest collection to keep it anywhere nearly of an up-to-date character. Where so many new varieties are introduced from such a number of sources it naturally follows that all are not equally meritorious. For those cultivators who have not the opportunity of inspecting the new varieties as first seen, I have compiled my annual selection of those I consider worthy to be added to any collection.

**CHELTONI** is a sport from that favourite white flowered Australian raised variety, *Nellie Pockett*, which for growing into specimen plant size or dwarf plants for decoration, as well as for cut blooms, it is equally useful. The newcomer is an exact imitation of its parent except in colour, which is a deep golden yellow. (Wells, Redhill.)

**MRS. ALEXANDER MCKINLEY** has narrow florets, drooping slightly in a graceful manner. The colour is pleasing, being yellow suffused with red. In growth it is of a sturdy habit, and not more than 5ft.

**MR. F. S. VALLIS** was raised by M. Calvat, and which is regarded as one of his finest introductions. The florets are of medium width, semi-drooping, and the flower is remarkably well built up in the centre. The colour, too, is distinct and pleasing, being a deep yellow, fading with age to a softer tint. I look upon this as quite one of the best of this season's novelties. Grown in a natural manner it is not more than 5ft high.

**S. T. WRIGHT** attains a large size in diameter; it is fully 9in and quite 5in in depth. The colour is pleasing crimson with a suffusion of purple, with a golden reverse. (Wells.)

**MAY INGLIS** is another of Mr. Pockett's introductions, growing to an immense size—9½in in diameter. The florets are broad, drooping slightly. The colour is somewhat difficult to describe. A pale yellow base, striped and flushed with rose in the early blooms. Later this colour is replaced by red or crimson.

**MRS. T. W. POCKETT** is not a giant in diameter, but it is a flower of excellent proportions. 7½in by 6in, thoroughly well built up. The narrow florets are irregularly twisted, split, and forked at the tip. The colour is rich yellow. This variety has been likened to *G. J. Warren* in style, but this is quite an error. It bears not the slightest resemblance to that variety in any manner, being entirely distinct from anything I know.

**MRS. HARRY ENMERTON** is in colour—chrome yellow—a pleasing variety. The long drooping florets are a trifle weak in the centre, at their base inclining to show a want of fulness. This defect may be prevented by catching the flower at the right moment.

**MADAME PAOLO RADAELLI** is quite one of the best of recent introductions as an incurving Japanese. The blooms are remarkably well built up, having broad, substantial florets. When early developed the colour is pale pink; later blooms flushed with rose. This variety should be added to every collection no matter how small.

**MAFEKING HERO** was sent out this spring by Mr. Godfrey, and it has well borne out the high opinion formed of it last November by those who saw it. The blooms, when fully developed, measure 9in in diameter, carrying a depth of quite 6in, which is a good proportion. The colour is dull red, the reverse being gold. The tips freely turn upwards, giving added character to the flower.

**MADAME WALDECK ROSSEAU** is one of the finest of incurving Japanese blooms in existence at the present time. The broad bronze red florets show to perfection on fully developed blooms. The inner surface when seen is a rich amaranth crimson. Under some methods of culture the bulk of the florets are reflexed. *Sensation* was first seen last season, and has this year fully borne out all that was said of it then. The broad flat florets are golden yellow,

flushed with crimson. *Earl of Harrowby* has long twisted florets, rich red in colour, and quite an attractive variety.

**MISS MILDRED WARE** in its formation resembles both *Vivian Morel* and *Madame Carnot*, but not either distinctly; but being between two such sterling varieties it cannot fail to become a favourite. The colour is distinct and attractive—crimson flushed with brick red. (Jones, Lewisham.)

**LADY MARY CONYERS** has loosely incurving florets, the surface colour being rose, the reverse a silver tint.

**GENERAL HUTTON** is truly a magnificent variety, having long loosely incurving drooping florets. The base colour is yellow faintly striped with red.

**LORD HOPETOUN** is of Australian origin, having long narrow florets of a semi-drooping character. The colour is an intensely rich crimson with a gold reverse, which is, however, seldom seen.

**MARY PERKINS** has long narrow incurving florets of a deep canary colour. The blooms are fully built up, making a handsome blossom. (Jones)

**MRS. E. HUMMEL** is shrimp pink in colour. The incurving florets coil in a peculiar manner, giving it a striking appearance.

**DUCHESS OF SUTHERLAND** reminds one very much of *Golden Dragon* in its best days. The broad florets are exceptionally long, drooping and curling inwardly. The colour—rich yellow—is very striking. In size it grows fully 9in in diameter and as much as 6in deep.—E. MOLYNEUX.

### The Collection at Heywood, Wilts.

Though no longer a patron of the exhibition hall as a competitor, Mr. Robinson still maintains his credit as a grower and competent judge of Chrysanthemum blooms. His collection at the present time comprises a preponderance of the Japanese section; incurved are fewer in numbers, and the Anemone and reflexed sections have been entirely abandoned. For home displays, however, the Japanese are infinitely the better for giving effective colour, boldness of character, and more variety, so that the absence of two sections and lesser extent of incurved are not likely to cause depreciation in the purpose for which they are needed. Among the newer kinds—and Heywood has long since been noted for its up-to-date selection—are some noble flowers and varieties, which, it may be said, are destined for further future use.

Mr. Godfrey's well-known set have, in the main, turned out admirable, and some of the Earlswood novelties are not one whit the less noteworthy. From the latter source Lord Alverstone stands out conspicuously as a very fine flower. Its depth of crimson colour, width of petal, and healthy constitution render it one likely to have a future before it. Mrs. E. Thirkell, too, had some immense flowers; as also had Duchess of Sutherland and General Hutton, both yellows, quite distinct in character. *Mdlle. Maria Liger* may be best described as an improved *Good Gracious*. *Matthew Smith* gives a pretty blend of crimson and gold, and quite an attractive flower. *Mafeking Hero*, *Henry Barnes*, *Earl of Arran*, *Charles McInroy*, dark chestnut crimson; *Guy Hamilton*, *Nellie Stevens*, *Henry Stowe*, strongly resembling the old *Belle Paule* in its best form; *Marquis V. Venosta*, *M. L. Remy* (fine), *Madame L. Remy*, *Madame Von Andre*, excellent. Lord Ludlow remains as youthful as a seedling both in colour, perfection, and vigour. Mrs. G. Mileham, Rev. W. Wilks, Ernest Bettisworth, Mrs. J. W. Barks, Mrs. J. J. Thorneycroft, Godfrey's *Sensation*, *Masterpiece*, pretty; Godfrey's *Pride*, *Queen Alexandra*, *Edward VII.* (the latter not being so striking in colour as some others); *Mutual Friend*, very pure; *Hairy Wonder*, W. R. Church, extra fine in colour and form; and *Edith Tabor*.

With these are *Madame Ed. Roger*, Wm. Higgs, and *Louisa Giles*, three interesting incurveds; *Jane Molyneux*, large and spreading; *Lily Mountford*, *Rayonnant*, old, but still deserving; *N.C.S. Jubilee*, and last, but not least, *Calvat's Sun*. This was an immense flower, beautiful in its clear yellow, and graceful character. The foregoing naturally include only those which happened to be on view at the time of my visit. There were others which are later, and naturally some that had already found a purpose in the decoration of the house.

Chrysanthemums were the favourite flower of the late Lord Ludlow, and received from him a liberal patronage; and this promises to be still fully maintained by J. W.

Miller, Esq., who has recently come into residence, and who has already found in Mr. Robinson an expert worthy of his confidence.—S.

#### The Last November Show of the N.C.S. at Royal Aquarium.

We are told that the last November show of the National Chrysanthemum Society has been held in the Royal Aquarium, London. Considering the kindness that has always been shown to us by Messrs. Ritchie and J. W. Wilkinson, and all their staff, we owe them a debt of gratitude. They have at all times met us with smiling faces, and never failed to give us exhibitors all the aid that lay in their power.

I remember the spot before ever the building was thought of. I watched its progress—then called a "London Winter Garden"—and also remember its first gardener, the late Mr. J. Wells, who assured the public it always would be full of flowers, but with the obscure light from an opaque roof, both the flowers and the fishes gradually vanished. Their place was supplied by the remaining portion of the original Stoke Newington Society, which had been located a few years in the Borough of Hackney, and had its committee room at the Four Swans, Bishopsgate, and afterwards this society and its shows migrated to Westminster.

I exhibited at Hackney, and of course also at the First Chrysanthemum Show in the Aquarium, and I have continued to do so ever since. The premier show had a good run, and at each succeeding show the exhibits increased, and the style of exhibiting and size of Chrysanthemums have been wonderfully improved upon. Southwark then held its shows not far off. Their committee complained of the Hackneyites poaching, and as a remedy I suggested to Mr. W. Holmes that it was time we should change the title of our society and call it NATIONAL, but when this proposition was brought before the committee the president (the late much respected Sir E. Sanders) denounced it determinedly, and he had many followers who were much devoted to the neighbourhood of its origin. However, Mr. Holmes, the first and much esteemed secretary, used great influence and weight, and the more ambitious title was ultimately adopted, and ever since then the society has gone forward by leaps and bounds. During all this time there has been a representative exhibition of Chrysanthemums worthy of this great nation. I only remember having been absent on one occasion from the whole series of exhibitions, and certainly never missed a November show. I have been especially fortunate in securing many high awards for exhibits from Swanley, and at these numerous meetings I have made many friends.—HENRY CANNELL, V.M.H.

#### At the Exmouth Nurseries.

Perhaps never in the history of the Chrysanthemum has it been the good fortune of any one raiser to offer such a magnificent collection of seedlings in one season as Mr. Godfrey did last year.

Apple, Edward's Coronation. (See page 451.)

On entering the large Mum house we exclaimed, "What a glorious sight!" for about 100ft in length was one blaze of colour, and in this house were all the novelties. Mr. Godfrey may well be proud of Godfrey's Pride; it is an immense bloom, without the least coarseness. The florets are broad, smooth, and of great length; slightly whorled, forming a good, solid, handsome flower.

Pear, Eyewood.

The colour is quite distinct, being a reddish carmine-crimson, with a lighter reverse. The plant is of good healthy growth, and of medium height, while the growth of all the seedlings are marvellous. Almost every variety has strong, sturdy growth, and the foliage is leathery, and of a healthy dark green colour. Every bloom seems to come with ease. Not one did I see with a hard centre.

Further down the house we come to Godfrey's Masterpiece—a lovely flower. One might call it a very large Indian-red form of Mons. Chenon de Leché, which just shows the tip of the florets with a rich golden yellow. Queen Alexandra is the most distinct variety I have seen. The colour is a delicate fawn or buff, flushed with carmine pink. Golden Eagle, an immense bloom: colour, a distinct shade of chrome. Exmouth Crimson, a large flower of excellent form, very distinct, and one that will be much in demand. Edward VII., a large handsome bloom of a claret crimson shade; quite distinct from any other variety.

Another most lovely flower is Bessie Godfrey: clear canary yellow, deepening towards the centre. Very large, deep bloom. Godfrey's Triumph: This is a seedling from Mons. Chenon de Leché. The form of flower is very superior, the petals being more recurving, showing the flower almost a perfect solid and rich ruby crimson.

Other seedlings noticed as of exceptional merit were Sensation, The King, H. E. Hayman, Wallace, E. Vowden, Nellie Stevens, Exmouth Rival, and dozens of unnamed seedlings full of promise.—G. FOSTER.

#### Pear, Eyewood.

Eyewood is a shapely little dessert Pear, good as a standard, with fair average bearing qualities, and spoken well of by those who know it best. Many of the trade growers, however, fail to catalogue it. At Chiswick it is cropping well this season, and specimens have reached us for name from various parts of the country. It is in order to bring this variety more prominently forward at this season that our notes and illustration of it are now published. In describing it in his "Fruit Manual," Dr. Robert Hogg supplies the following facts: "Fruit, below medium size, 2½in wide, and 2in high; Bergamot-shaped. Skin, very thick, green on the shaded side, becoming greenish yellow tinged with brown next the sun, and very much covered with pale brown russet, and large russet dots. Eye, small and open, slightly depressed. Stalk, 1in to 1½in long, slender, inserted in a small cavity. Flesh, yellowish, exceedingly tender and melting, very juicy, with a sprightly vinous flavour and a fine aroma. A very excellent Pear; ripe in October. The tree is very hardy, and a good bearer. Mr. Luckhurst finds it only second-rate, and Mr. Blackmore says it is 'small, of poor quality.' This was raised by Mr. T. A. Knight, President of the Horticultural Society, and was named after Eyewood, near Kington, in Herefordshire, and not, as has been stated, on account of the peculiar woodiness of the eye. Mr. Knight named all his seedlings after the residences of his friends."

### A Letter from Calcutta.

"MY DEAR JACK,—It is with fear and trembling that I pen this note to you, as no doubt by this time I am almost beyond your forgiveness for not writing to you beforehand, and especially as I promised to do so before leaving England. However, I won't fill this sheet with excuses, but really the time seems to fly since I came here, and having to leave England a week before I expected, my departure was rather hurried. I arrived here all right after a fairly pleasant voyage. . . . I am pleased to say the hot weather is practically over now (22-10-02) without my having had any bad effects from the same. Last month was the worst of the lot, because the soil being so very wet, owing to the heavy rains in July and August especially, the hot sun caused the atmosphere to be exceedingly moist. At nights one would perspire with only a sheet over one. However, for the next four months the Bengal climate is said to be a lovely one, and I am looking forward to something better.

"The growing period of the vegetation is practically over, and everything is looking its best in the way of foliage. The spring is the time when most of the plants flower, but of course there is always something in bloom, and some plants flower almost all the year round. Brownias, Amherstias, Lagerstræmias, the lovely Poinciana regia, &c., flower in spring and early summer. Many Palms are now in flower. Oedoxa regia, of which there is here a fine avenue, is throwing out its large flower spikes.

"The grandest plant in flower for some time has been Colvillea racemosa. It is a tree growing to a height of 50ft or more, with rather a long bare stem; the branches spreading in a drooping manner from the top. These latter have been for the last fortnight furnished with many large racemes of small, orange-red flowers—really a brilliant sight from a distance. There is also a lovely tree of Kydia calycina in flower. The long panicles at the end of every branch are presented in much the same manner as Hydrangea paniculata. In fact, when I went up to it and casting a casual glance, the clusters reminded me of that plant very much. Taking into consideration the bushy habit of the tree, and its height—30ft or 40ft—you can imagine what a lovely sight it is. It has to be seen in the morning, however, as the flowers soon fade. It would be about seven o'clock when I looked at it, and hundreds of bees and butterflies were swarming amongst the pinkish white flowers.

"Antigonon leptopus is one of the prettiest climbers I have seen here. One half of the roof of one of our plant houses is covered with it, and for the last six months, it has been constantly in flower. There are two varieties, a white and a pink one, and all day (but best in the morning) the roof is a mass of white and pink. Crotons are at their best, as they have made their summer's growth. Dracænas have also fine foliage. Allamandas and Ixoras have been flowering all summer, and Begonia magnifica is flowering well. I saw an article recently about the Amherstia nobilis. We have a fine avenue of it, and during March and April it is a fine sight. It seeds here, but not freely, and we have raised two or three dozen seedlings. A drawback as regards the seed, and one which, no doubt, renders it scarcer in other countries, is that they lose their vitality within four days after falling from the tree, so that immediate sowing is necessary. We also raise them from layers, and by this method we get earlier flowering plants.

"The way we layer them may be interesting to you. A good strong bamboo cane is fixed into the ground, the top coming in close contact with the branch to be layered. It is then split four or five times from the top down about a foot, and a pot of soil is firmly fixed in the centre. The branch is layered into this about May or June. Until the rains start in July these require watering, and by the end of September they are rooted and ready for the nursery, where they are kept until next rainy season, the time for planting.

"Next to this avenue of Amherstias we have one of Brownias. These flower about a month earlier than the Amherstia, and for beauty rival the latter. I came across a large patch of Exacum zeylanicum in the grounds to-day. It was growing amongst the long grass, and would be considered as jungle here. In my list of plants in flower I should also mention Cassia glauca, which is a lovely sight, with clusters of yellow flowers at the ends of the branches. I should include Cassia grandis, although it does not nearly come up to the first as regards flowers, but is a larger and generally a finer tree.

"Several of the trees are beginning to lose their leaves, as most of them do in the cold season. There is a difficulty keeping grass down in the rainy season; it grows so fast. We have always eight to ten mowers working, as well as a mowing-machine, such as they have for cutting hay at home. The flower

garden foreman, or mallee, is busy getting his place ready for the cold-weather bedding, which would be called summer bedding in England. Seeds are obtained from English nurserymen, and the usual summer annuals, Pelargoniums, and such like, are obtained from Darjeeling, as it is impossible to keep these in Bengal during the hot weather. I have not, as you know, had the opportunity of seeing the flower garden at this season, but I am told the plants grow and flower exceedingly well; and what with the lovely climate and such a variety of plants which can be utilised, the flower garden might well be a beautiful sight. There are a fine lot of Orchids here, but few are in flower at present. A batch of Vanda cærulea will soon be on view. I was looking at them to-day, and saw that there was a fine lot of spikes.

"Well, dear Jack, I fancy I might go on for another hour describing the plants here, but I shall leave something for a future time. My work is principally looking after the work-people. We have at present on the books about 100 coolies, 50 women, 20 mallees, or gardeners, and 30 boys."—ERNEST.

### Chrysanthemums at Westbury.

There seems ample justification for the exception taken on page 389 in regard to the merits of the variety Margaret Marwood. In Messrs. House's nursery, as I intimated, there are such a great range of variety, many good, others indifferent, that in a hurried inspection it is not a difficult matter for one error to be made in the case of variety. Inquiries of the Messrs. House elicit the remark that they have thirty better sorts, and the commended one being so closely contiguous to the one for which commendation was intended—Shasta—accounted for the slight confusion of tallies. This is the best, freest, and dwarfest of the whole range of Moon Daisies, another excellent one bears a popular title—Lord Roberts.—W. S.

### Vegetable Pests.

I noticed an article in the *Journal of Horticulture* last week, page 403, headed "Vegetable Pests," and signed "John Rylance." If Mr. Rylance will take a small stick and make a hole on one side of the Cabbage affected, about 3in deep and 2in or thereabouts from the stock, and put half a teaspoonful to a teaspoonful of paraffin oil into the hole, the quantity to be regulated according to the state of the soil, the paraffin will permeate through the soil, and as soon as the plant is reached the pest will "tak' the road." It is not too late to apply the remedy so long as there is life in the plants; but, of course, when the plants are so far gone it will be longer before they get into health again. Intelligently and judiciously applied, nothing but good will result from the application.—J. F. L.

### Tomatoes for Early Fruiting.

In a recent issue of the *Journal*, September 11, page 251, I note "J. H. W." advocating the removal of the anthers as a means of pollination of the Tomato in winter, a process with which I have had no experience, and it may prove better than my suggestion, which I offer if accepted. Some years ago, when a foreman, I had tried different ways of pollinating Tomatoes without much success, and being advised by a friend to get some cow manure, which I did, and put about a 6in potful, 2ft or 3ft apart, convenient to the pipes, and covered it with a little dry soil, and in a few days small flies by the hundred appeared, when the manure would be turned or shifted. The flies made friends with the Tomato flowers with fairly good results. The smell from the manure is anything but pleasant for a time. Having tried the above several times since, I have had no trouble in getting a fair set.—J. M. C., Ballyarthur, Woodenbridge.

### Fruit Trees Pruned or Not Pruned at Planting.

If your correspondent, Mr. A. Petts, is of opinion that he has thrown light upon the controversy on this point, I can only say that the light has not dawned upon me yet. In one place he says: "Thus we see the working of this general principle—cutting back a newly-planted tree induces vigour of growth; leaving them unpruned leads to fruitfulness (and probably unsightly naked branches) even before the tree is strong enough to support it." In another place he writes: "Deferring the cutting back of the trees till after a season's growth adds to their vigour of growth." If these two sentences are not directly contradictory I do not understand the English language.—OBSERVER.

P.S.—Will any reader who grows Cob-nuts tell me whether the trees should be cut back when planted, and, if so, to what extent?

# NOTES & NOTICES

## Royal Appointment.

Messrs. Richard Sankey and Son, Limited, Bulwell Potteries, Nottingham, makers of the Sankey garden pots, have received the Royal Warranty as manufacturers to His Majesty the King.

## The Sutton Christmas Rhubarb.

We omitted to state in our report of the R.H.S. meeting on November 4, that the Sutton Christmas Rhubarb exhibited by Messrs. Sutton and Sons was given an Award of Merit by the Fruit and Vegetable Committee.

## Horticultural Benefit and Provident Society.

The usual monthly committee meeting of this Society was held at the Caledonian Hotel, Adelphi Terrace, Strand, on Monday evening last. Mr. C. H. Curtis presided. Nine members were reported on the Sick Fund, the amount of sick pay for the month being £31 7s. 2d. Seven new members were elected, making a total up to the present time this year of eighty-six. The secretary was authorised to obtain 3,000 circulars for distribution.

## School Closed for Potato Lifting.

The School Board of Kirkbean (N.B.), in the Stewartry, have closed the public school for a fortnight to allow of the Potato gathering—a method adopted to save the average attendance. Kirkbean is a well-known district for Potatoes, and during the gathering of the crop all available hands are employed. The majority of the School Board are farmers.

## British Therapeutical Society.

The purpose of the new British Therapeutical Society is to determine the medicinal properties of all kinds of natural products. Especial attention will be given to plants locally credited with curative powers, and it is expected that many substances of value will be found.

## The Carriage of Fruit.

A deputation representing some of the principal fruit-growing counties has waited on the general managers of the principal railways in London to urge on them the necessity for improvement in fruit transit. The deputation was arranged by the National Fruit Growers' Federation, and was introduced by Colonel C. W. Long, M.P., its president. The points urged were a better system of loading, quicker delivery from terminus to market, and more prompt return of empties, refrigerator cars, and covered trucks, uniform mileage rate for fruit, and a more favourable interpretation of owners' and companies' risks. The managers' chairman promised that the proposals should receive careful consideration.

## Vallota purpurea.

The Scarborough Lily is to-day represented in many gardens by a potful of crowded bulbs, these being left well alone, and should they blossom forth and furnish the beautiful crimson amaryllidaceous flower scapes mayhap their reward will be a better position on the plant stage until such time as they die down again, whence the bulbs are more or less neglected. This does not obtain everywhere, and many gardeners bestow considerable attention on their batches of *Vallota purpurea*. Good bulbs are an imperative necessity if the best flowers are expected. The potting is usually accomplished during February or early March, 6in or 7in pots being used. All small bulbs adhering to the parent ought to be taken off, to be placed in pans and grown on. The apex or neck of the bulbs should be level with, or slightly above, the surface of the soil. When growth begins the plants should be placed on an airy greenhouse shelf, where they may well be kept until about the flowering time, which is varied, according to the grower's desires. Good bulbs potted very early in the year are flowering now, or a little earlier than the present, and others flower from May throughout the summer. In the mildest parts of the country this plant succeeds out of doors, and is treated like the *Belladonna* Lily. An illustration appears on page 453.

## The Royal Gardeners' Orphan Fund.

The Right. Hon. the Earl Carrington has kindly consented to preside at the next anniversary festival of this charity, which will take place at the Hotel Cecil on Tuesday, May 5, 1903.

## Ipswich Mutual Improvement Society.

The latest meeting of the above association, held on November 6th, was devoted to the consideration of the seasonable subject of "Spring Bedding." Mr. J. Battram, of Oaklands Gardens, Ipswich, introduced the subject with a very able paper. Dutch bulbs, Wallflowers, Polyanthus, Myosotis, Arabis, Alyssum, Silene, &c., were mentioned as particularly adapted for planting in borders and beds. Concise instructions were given for the preparation of plants for spring bedding, together with many useful hints as to grouping with regard to colour. The discussion was opened by Mr. Cotton, and sustained by the chairman (Mr. W. Chandler), Messrs. Morgan, A. Creek, Close, &c.—E.

## Yeovil Begonias.

Messrs. B. R. Davis and Sons, Begonia specialists, Yeovil Nurseries, Somerset, were able to send to us a large boxful of selected tuberous Begonia blooms, from plants in the open air, a week ago. They remark, "We think you will agree with us that it is a remarkable season which permits such flowers to be gathered so late in the year, and is a tribute to the value of the Begonia as a bedding plant. Of course, the flowers are smaller, but the colouring is very bright." The colouring was certainly intense and rich, the size and substance of many of the blooms being little inferior to the best plucked in summer's heyday.

## Apple, Edward's Coronation.

This variety was exhibited by Mr. H. C. Princep, gardener to the Hon. H. B. Portman, of Buxted Park, Uckfield, Sussex, before the Fruit Committee of the Royal Horticultural Society, on October 20, when an Award of Merit was accorded to it. Our illustration on page 449 depicts the exact size of a typical specimen, though some are larger and some smaller. It has one side rather heavier or more developed than the other. The skin is greenish yellow, streaked and mottled red on the side next the sun; eye set in a round depression, somewhat deeply, and wide; stalk straight, stout,  $\frac{1}{2}$ in to  $\frac{3}{4}$ in long, in deep round cavity. Flavour very good. It is slightly over medium size and roundish.

## Royal Horticultural Society.

The next fruit and flower show of the Royal Horticultural Society will be held on Tuesday, November 18, in the Drill Hall, Buckingham Gate, Westminster, 1 to 4 p.m. A lecture on "Spraying Fruit Trees and Packing Apples, as Practised in Canada," will be given by Mr. Cecil H. Hooper, F.R.H.S., at three o'clock. At a general meeting of the Royal Horticultural Society, held on Tuesday, November 4, forty new Fellows were elected, amongst them being Lady Julia Follett, Major Charles A. Leslie, Major George A. Marshall, and the Hon. Mrs. Harbord, making a total of 1,045 elected since the beginning of the present year. The Society's annual examination in the principles and practice of horticulture will be held on Wednesday, April 22, 1903. Full particulars may be obtained by sending a stamped and directed envelope to the Society's offices, 117, Victoria Street, London, S.W. The questions set at all the previous examinations are now published, price 1s. complete.

## Echoes from Hamilton, N.B.

The weather is keeping open and mild for the opening month of winter. The result is (partly due to this fact, together with the general lateness of the first season) that foliage of all kinds part with less readiness from trees, shrubs, or herbs, than usually is the case. This tends to keep things naturally longer messy and untidy, but a night of rain, succeeded with a degree or two of frost, would decide the matter, and very possibly this will not be long in presenting itself now. The members of the Hamilton Horticultural Association and a few friends met Mr. Moir, head gardener at Earnock, on the occasion of his leaving the district, in the Commercial Hotel, on the evening of the 6th, to present him with a tangible token of their high respect for his uniform courtesy to all classes of the community whose duties brought them in contact with him. The presentation took the form of a gold chain and watch and a purse of sovereigns.—D. C.

**A New and Destructive Apple Rot.**

An unusual and serious trouble with harvested Apples has appeared in Western New York. It is confined entirely to scabby Apples. A white or pinkish mildew appears upon the scab spots and transforms them into brown, sunken, bitter, rotten spots. On very scabby Apples these rotten spots soon coalesce and ruin the fruit. The damage done is enormous. In Niagara, Orleans, Monroe, and Wayne counties, thousands of barrels of Apples have been ruined. The varieties most affected are Greening and Fall Pippins.

**A Phenomenal Season.**

Despite the lateness of the season fruit and flowers grown in the open are still being gathered in various parts of the country. Raspberries have been plucked near Leeds, and at Lydney, Gloucestershire: Plums have ripened at Epsom; fresh Primroses have been gathered at Wandsworth, and blossom from a Laburnum tree now in flower at St. Margaret's, Devon, in which county wild Strawberries are still being picked. Apple blossom, too, has been obtained from Weybridge, Surrey. At the same time, it may be noted that corn is being cut at Sandwick, in the Shetlands, as green now as in its early growth. Green Peas were being picked at Newport (Essex) on Saturday last, and ripe Strawberries are still to be gathered in the open.

**Reading University College.**

The fees usually charged in horticultural colleges are beyond the means of the ordinary gardener, who is none the less conscious that his chances of passing the Royal Horticultural Society's examination would be greater if he could supplement his practical training by spending a short period in the laboratories of a horticultural college. At Reading, a limited number of men of this class are granted a course of free instruction for six months, and a maintenance allowance, together with railway fare to and from Reading. They are required to devote their time between work in the laboratories in preparation for the R.H.S. examination, and in the College Gardens at practical work under the direction of Mr. Patterson. Particulars may be obtained of the Registrar, Reading University College.

**Scottish Horticultural Association.**

A meeting of the Scottish Horticultural Association was held on November 4 at 5, St. Andrew Square, Edinburgh, Mr. Charles Comfort, president, in the chair. There was a large attendance. A paper was read by Mr. John Anderson, Greenside Place, Edinburgh, on "Horticultural Exhibitions and their Commercial, Educational, and Social Aspects." Forty new members were elected. Among the exhibits shown were a collection of flowers from the open border, consisting of thirty-six distinct species and one hundred varieties, by the president; twenty-five varieties of Cactus and pompon Dahlias, by Messrs. R. B. Laird and Sons; a collection of Plums, Apricots, and Cherries, from the open wall, by Mr. Webster, Gordon Castle, Fochabers; and two very fine varieties of Pentstemons, by Mr. Smith, Oxenford Castle.

**Coggeshall Royal Root Show.**

The annual root, cereal, and vegetable show in connection with the firm of Messrs. John K. King and Sons, seedsmen, of Coggeshall and Reading, which was so successfully revived some three years ago by the present enterprising members of the firm, Mr. Herbert T. King and Mr. Leonard G. King, was held at Coggeshall on Tuesday, October 28. Essex is a seed-growing centre, and by far the larger proportion of seeds used in the country and exported all over the world, are grown in Essex. The centre of the industry in this county is Coggeshall, and it was here as long ago as 1793, that Mr. John K. King established the seed-growing firm now so widely known as Messrs. John K. King and Sons. The huge warehouses cover nearly a quarter of a mile of ground. The founder of the firm originated the principle of growing seeds from pedigree selected specimens. Exhaustive experiments have shown beyond doubt that crops grown from pedigree seeds are from 25 to 40 per cent. heavier, while their value for feeding purposes is proportionately higher. To illustrate the value of pedigree-grown roots and their superiority over all others, as well as to meet their customers from all parts of the kingdom, Messrs. John K. King and Sons have instituted their Royal Root Show. It may be added that the firm have enjoyed the royal patronage for many years, and are now seedsmen to H.M. the King.

**The Fruiterers' Company.**

The prize of twenty-five guineas and the gold medal which were offered by the Fruiterers' Company for the best essay on "Gathering, preparing, packing, and profitably disposing of home-grown fruit and vegetables by cottagers and others with small holdings," has been awarded by the judges appointed by the company to Mr. R. Lewis Castle, the manager of the Woburn Experimental Fruit Farm, Ridgmont, Beds. Mr. Castle's essay will be published by the company at a nominal price, and it is hoped and believed that it will form a valuable and useful manual on the subject with which it deals.

**October Weather at Belvoir Castle.**

The prevailing direction of the wind was N.E., total six days. The total rainfall was 2.31in; this fell on twenty-two days, and is 0.77in below the average for the month; the greatest daily fall was 0.46in on the 13th. Barometer (corrected and reduced), highest reading, 30.485in on the 24th at 9 a.m.; lowest reading 29.304in on the 15th at 9 p.m. Thermometers: highest in the shade, 60deg on the 13th; lowest, 29deg on the 19th; mean of daily maxima, 53.90deg; mean of daily minima, 42.45deg; mean temperature of the month, 48.17deg; lowest on the grass, 25deg on the 19th; highest in the sun, 104deg on the 12th; mean temperature of the earth at 3ft, 51.67deg. Total sunshine, 52 hours 5 min, which is 42 hours 43 min below the average for the month; there were ten sunless days.—W. H. DIVERS.

**Feather in Tomatoes.**

Our contemporary, "The Gardener," in its issue of November 8, describes and illustrates a so-called new and serious disease, to be known as "feather," affecting Tomato foliage. The plant figured is one of several grown in the Lea Valley in large, well heated and well ventilated structures to produce fruit for market. Many plants are normal in leaf and fruit, and not a few are abnormal in foliage, being in the condition known as "feather," and, though flowering somewhat boldly, not producing any fruit. In some of the structures only a few plants are affected with "feather," some plants having normal growth and fruit, and also abnormal formation and no fruit, the normal growth being the first, the abnormal the succession. In most instances, however, the young plant has normal lower leaves, and after being planted out and advanced for fruiting develops "feather," and the production of fruit is nil.

**The Late Mr. Charles Maries.**

This noted plant collector and horticulturist passed away on October 11 at a comparatively early age. "The Garden" publishes the following notes of his career: "He was in the employment of Messrs. James Veitch and Sons, when, in 1876, he was entrusted with a mission to explore part of China, Formosa, and Japan, with a view to introducing into Europe some representatives of the splendid vegetation which was known, or was only supposed to exist, in these countries, and especially in the great Ichang Valley. Mr. C. Maries succeeded in sending home and in good condition such plants as *Platycodon grandiflorum* Mariesii, *Rodgersia podophylla*, *Abies Mariesii*, *Styrax Obassia*, *Pteris longifolia* Mariesii, *Hamamelis mollis*, *Hydrangea Hortensia* Mariesii, and the charming *H. Hortensia rosea*, which deserves a much more extended cultivation than it receives at present. He also reintroduced the long-lost and very pretty *Caryopteris Mastacanthus*, and a host of other plants of equal merit. His success in introducing these plants is all the more remarkable if we take into consideration the difficulties with which collectors had to contend in those days of comparatively slow navigation, and was mainly due to the care, and, I may add, also the ingenuity he displayed in the packing and forwarding of these plants to which he was so devoted. Later he was appointed superintendent of the Gardens of Durbhungah, and ultimately of the magnificent gardens of Gwalior, where he made some very extensive alterations and improvements during the many years that he had them under his direction. That Mr. C. Maries had well employed his time, and that his exertions were well and duly appreciated, is evident from the fact that, besides being an occasional contributor to the gardening papers and to the Journal of the Royal Horticultural Society, he was also a Fellow of the Linnean Society, and was one of the recipients of a Victoria Medal of Honour. To his widow, his son, and his daughter we offer our deepest sympathy."

## THE CACTUS DAHLIA IN GARDENS.

For several years in succession I have taken a day's cycle run into the country to the same destination, a run of some twenty-five miles, through a number of small hamlets and villages in Sussex, and, being "a Dahlia man," naturally the Dahlia catches my eye at once whenever and wherever it may be. I do not know

Dahlias were less in number, but the only old variety that was left in force was Constance, and the others were Cactus sorts, notably Starfish and Countess of Lonsdale, with sometimes a Night, and one or two others.

I was, indeed, struck to see that, although to look at the houses, &c., one would imagine that they had not altered for fifty years, yet the Cactus Dahlia had found its way even here, and I could not help smiling at what I had read in various gardening

VALLOTA PURPUREA. (See page 151.)

whether this particular route is favoured with an extra supply of the autumn favourite, but this I must say—that it appears to be the predominant feature in quite nine out of ten of the front gardens of cottages the whole way.

This fact was very striking some three or four years back. Then there was scarcely a flower resembling a modern Cactus Dahlia. I remember calling out the name of Constance, Cochineal, General Gordon, and one or two others repeatedly as we rode by, it being somewhat interesting to see the old stagers again and in good form, too. This year, however, they were gone; quite a change had come over the gardens. Not that the

papers, from one signing himself "A. D.," who still contends that Cactus Dahlias are a failure in the garden. Surely no man could expect to exact more bloom from a plant of any sort than I saw on hundreds of Dahlias as late as this present week (November 5).

I have often wondered where the enormous number of green plants turned out yearly by some of our retailing firms went to, but it is now, to a certain extent, no longer a mystery. If all the country over is changing "decoratives" for "Cactus" at the same rate as in this part of Sussex the demand must be indeed phenomenal.—DAHLIAIST.

## Societies.

### R.H.S., Scientific Committee, Nov. 4th.

Present: Dr. M. T. Masters, in the chair; Messrs. Worsley, Baker, Michael, Saunders, Bowles, Odell, and Hooper; Drs. Rendle and Cooke; Rev. G. Henslow, Hon. Sec.

*Ergot, Prevalence of.*—Mr. Hooper observed that this disease was particularly abundant this season, and exhibited specimens in Cocksfoot and Rye Grass. It generally is frequent in wet autumns.

*Apple Trees in Blossom.*—He also referred to the occurrence of flowers on Apple trees, a fact, elsewhere noted in the papers, due to the mildness of the weather. Dr. Masters observed that when such flowers occurred on spurs, they were dissociating next year's buds; but on terminal shoots they were additional growths.

*Tomatoes and Bordeaux Mixture.*—He also called attention to the advantage of using this fungicide, which were shown by outdoor Tomatoes having completely failed when left to themselves; but those sprayed bore at least half a crop this autumn.

*Crocus, rare var.*—Mr. Bowles showed a blossom of *C. speciosus* var. *Aitchisoni*, which bore a fine pale-coloured flower; the country was not known whence it was received.

*Cypripedium Malformed.*—Mr. Saunders showed a drawing of a flower having the labellum erect and one additional petal. Dr. Masters undertook to add further details.

*Apple Leaf Black Mould.*—Dr. M. C. Cooke reported as follows upon the Apple leaves submitted for examination: "They were badly diseased with the attack of a black mould new to the British Isles. The leaves were dead or dying at the ends of the branches, and the under surface sprinkled on the dead parts with black dots, which proved to be the tufts of conidia produced by *Coniothecium Oestieri* (Desm.), which was found and described in France in 1857 on leaves of *Cornus sanguinea*. The conidia are brown, very variable both in form and size, and muriformly septate, clustered in glomerules, and mixed with a few slender threads. This parasite has appeared so seldom that no experiments have been made upon it, but it is recommended to strip off and burn, and sweep from the ground all fallen leaves, so as to prevent the diffusion of the pest. Even when this is done, if there is any foliage left, it should be sprayed with one of the copper solutions to destroy the germinating powers of the conidia."

*Flax Wilt.*—Dr. Cooke communicated the following paper: "Since the last meeting of the Committee I have learnt that experiments have been undertaken in the N. Dakota experimental station (bulletin No. 50) to ascertain the cause of the disease known as 'Flax wilt' and 'Flax sick soil,' a disease which appears to be known in Ireland, as well as in Belgium, Germany, and other Flax-producing countries of Europe. I may premise that it has long been known that Flax cannot be grown continuously for any long period upon the same soil, because then the soil becomes 'sick' and the Flax seedlings die off and do not produce a crop. The cause of this has hitherto been a mystery, mostly attributed to the exhaustion of the soil. The result of these experiments appears to be, not the exhaustion of any of the chemical constituents of the soil, but the prevalence of a minute fungus in the soil, which preys upon the debris of the previous year's crop, and attacks the young seedlings of the new year, causing them to wilt and die. The name of this new fungus is *Fusarium lini*. Apart from the elucidation of this particular disease, I think that the subject must be of interest to this committee, since there is no reason for supposing that this is a solitary instance of the phenomenon, and that other cases of failure in successive crops, and of the wilting of seedlings, may possibly be due, in like manner, to the presence of fungus mycelium and conidia in the soil, so difficult to determine, and sometimes attributed to exhaustion of the soil. The methods adopted in this instance may serve as a guide to the course to be pursued in similar instances, and although they may entail considerable labour, appear to offer an adequate reward. At any rate, this communication justifies the action of the Department of Agriculture of the United States in establishing experiment stations, where these problems may be solved at the expense of the State. In the present case it is recommended that cultivators should cease growing Flax year after year upon the same land, and that at least three other crops should intervene between Flax crops; and that as much of the old Flax straw and stubble as possible which remains on the ground should be burnt forthwith, and that the Flax seed, before sowing, should be cleaned and treated with formaldehyde, according to instructions."

*Tumour of Potato Tubers.*—Dr. Cooke supplied the following additional facts upon this disease, lately reported upon: "It was attributed to a newly described fungus under the name of *Chrysophlyctis endobiotica*. Although at the time I advocated its decided affinity to the tumour of Beetroot. More recently specimens have been sent to Berlin, with the result that Dr. Magnus has not only confirmed this affinity, but has demonstrated that it is the same species, which is known as *Oedomyces leproides* (Trabut), so that the 'Beetroot tumour' and the

'Potato tumour' are caused by the same fungus. This should be noticed, since the form on Potatoes has for two years been destructive in several localities in the British Isles, and is quite capable of infesting Beetroot in like manner."

*Iris Black Mould.*—Dr. Cooke also reports upon diseased Irises sent to the Committee: "Since the last meeting a plant of *Iris ochroleuca* has been submitted to me for examination. The roots were in a perfectly sound condition, but the leaves were affected in a similar manner to those of other specimens sent to the Committee recently, and of which I find no record in the reports of our meetings. As this disease is apparently common, it is advisable that some allusion should be made to it for reference on a future occasion. The leaves turn yellow and sickly, and then brown, dying towards the tips. Upon these brown patches occur sooty or blackish spots, often of considerable extent, rather velvety under a lens, which manifest the appearance of a black mould (*Heterosporium*). The tissue beneath is permeated by mycelium, and the mouldy spots are often an inch or more in length, occasionally bounded by a darker line. The threads, or conidiophores, are erect, brown, septate, nodulose, often flexuous, and of an olive colour ( $70 - 90 \times 10 - 14 \mu$ ). At the apex, or laterally, the conidia are produced, either singly or two or more together, and are large, elliptical or oblong, with from one to three septa, or cross divisions, with the ends obtuse or rounded. The whole surface is granular, or warted, and of a pale olive colour ( $35 - 70 \times 14 - 20 \mu$ ). When mature these conidia are capable of germination from each individual cell, so that each conidium may be regarded as compound, and equivalent in reproductive power to as many conidia as there are cells in the original conidium. It occurs on the leaves of *Iris*, *Freesia*, *Antholyza*, and *Hemerocallis*, and is known, not only in Europe, but at the Cape, New Zealand, and the United States of America; and will be found described in Massee's 'Plant Diseases,' pages 321 and 440, and figured in this Journal on plate v., fig. 90. Spraying with potassium sulphide is reported to check the disease, and all diseased leaves should be cut off and burnt. If these precautions are attended to, and the foliage is not watered, the disease may be controlled. Also spraying with ammoniacal copper solution checks the disease, after clearing away diseased leaves."

*Grubs with Sedums.*—Mr. Saunders reported as follows on some specimens sent by Mr. Maynard, Wymondham, Norfolk: "The grubs sent with the enclosed letter are the grubs of one of the weevils, either the black Vine weevil (*Otiorhynchus sulcatus*) or the clay-coloured weevil (*O. picipes*), but the grubs of these species are so much alike that it is almost impossible to tell them apart. However, as the life history of both is exactly the same, it does not make much difference, from a cultivator's point of view. The parent weevils lay their eggs at the roots of various soft-rooted plants, Sedums, Primulas, Begonias, Cyclamens, and Ferns being great favourites. The weevils themselves are also very destructive to the foliage and tender shoots of Vines and many other plants, particularly Ferns and Dracenas. I do not know of any means of killing the grubs but picking them out from among the roots. Any insecticide that would kill the grubs would certainly be equally destructive to the plant. The beetles are not often seen, as they feed at night and hide themselves very carefully during the day. They may be caught by putting a white cloth under the plant that they are attacking before it becomes dark. If the plant is in a pot it is better, if possible, to lay it on its side; then, after it has been dark for an hour or so, throw a strong light suddenly upon the plant. This will generally cause the weevils to fall off, when they will easily be seen on the cloth; if they do not fall, give them a jarring shake, and search it well. Small bundles of dry moss or hay make good traps; they should be laid on the soil in pots near the stems of the plants, or, in the case of creepers, tied on to the stems or shoots, so that when the weevils are seeking shelter they should find one close at hand. These traps should be examined every morning. These weevils are either black, and about half an inch in length, or of a dull, pale, yellowish-brown colour, and about a quarter of an inch in length, according to the species." A vote of thanks was recorded to Dr. Cooke and Mr. Sanders for their valuable papers.

*Partial Separation of Parental Characters in a Hybrid Orchid.*—Mr. Hurst sent a flower with the following communication: "A plant of *Paphiopedilum* x *Canhami* (*P. superbiens* x *P. villosum*), which hitherto has always produced normal flowers with me, has now produced the curious flower exhibited. One side of the lip or slipper is normal in colour, being evidently a fair blend between the parent species. The other side of the lip may be divided into three distinct areas: (1) a narrow band of rich brown purple, as in the parent *P. superbiens*; (2) a broad band of greenish yellow, as in the parent *P. villosum*; (3) the remainder of the lip being a normal blend between the two parents. We have here evidently a partial separation of the mixed 'blood' of the parent species, the result being a mosaic rather than a blend. It is interesting to note that the hairs within the lip are sharply separated, as in the colour, and there is also a slight tendency to separation in the colour of the dorsal sepal and the petals. Whether this partial 'sport' will prove permanent remains to be seen, though it is not very likely. We

really know very little about the manner in which the cells of hybrids are determined and formed, but this particular case suggests that when the cells were being formed in areas (1) and (2), the parental determinants, instead of working together to form a blend, somehow separated, the *P. superbiens* determinants alone forming No. (1) area, and the *P. villosum* determinants forming the other (No. 2). Similar 'sports' have been recorded in the allied hybrid *P. x Harrisianum* (*P. barbatum* x *P. villosum*), for the history of which see: *Cypripedium x Dauthieri* Rossianum, Rehb. f. in 'Gard. Chron.', 1888, i., page 425. *C. x D. marmoratum*, 'Rev. Hort. Belge,' 1889, page 241, with plate. *C. x D. Dimidiata*, 'Gard. Chron.', 1895, i., page 335, fig. 45, cf.; also 'Orch. Rev.', 1894, pages 20, 147."

**Acorns from the Cape.**—Mr. Henslow showed specimens illustrating the great amount of variation occurring in the size and shapes of acorns from trees growing in and near Cape Town. They are all from original importations from Europe of the common Oak. One tree was remarkable for bearing a large number, all of which had three embryos. They were cultivated by the Dutch more on account of the acorns for pigs than for timber, as this is rather inferior to English Oakwood. Numerous avenues have been planted in the colony.

**Self-burial of Bulbs.**—Mr. Worsley showed a bulb formed below the previous one; and had come to the conclusion that its position indicated the, so to say, intention of Nature to deepen the position of the bulb. It bore numerous contractile roots of the usual spindle-shaped form, which were strongly wrinkled at the base. Mr. Henslow called attention to a paper on this subject ('Bot. Gaz.', xxxiii., page 401) on Californian Liliaceæ, of which some bury their bulbs (as does *Colchium*) by means of the rhizome alone, without contractile roots; while others do it entirely by aid of these organs.

**Wireworm.**—Mr. Balfour mentioned that these pests had been very troublesome this season, particularly where mineral fertilisers had been used. On a very poor chalky bank some Vetches were very badly attacked, especially on some long slips, which, for experimental purposes, had been dressed with potassic and phosphatic fertilisers. On these slips fresh shoots were continually being produced and destroyed. Another field near, situate in the valley, was planted with Prince of Wales Peas, and some rows of these also received dressings of the same fertilisers. A fine crop resulted notwithstanding wireworm attacks. Turnips were drilled between the rows, and these were badly attacked, especially where the mineral fertilisers had been used for the Peas. Although the Turnips were badly pierced, they were much finer otherwise than on the rows where these fertilisers had not been used. It is admitted that much organic matter favours wireworm, but the interesting point here is that very little humus in the soil growing Vetches, and the attack was much more severe where the mineral fertilisers were used. It may be noted that the Vetch is not often much injured by wireworm; suggested that possibly the more robust growth of the leguminous plants (Vetches and Peas) produced a more palatable and suitable food than the adjoining plants. In the case of the Peas and succeeding Turnips, a possible explanation may be that the increased vigour of the Peas, induced by the minerals, largely increased the supply of combined nitrogen, and this, in conjunction with the residual minerals, produced more succulent Turnips, which were, therefore, more favoured by the pests."

### Bournemouth Chrysanthemum, Nov. 5 and 6.

The sixteenth annual exhibition of the Bournemouth and District Chrysanthemum Society was held in the Volunteer Drill Hall, Holdenhurst Road, on the dates given. The open classes were represented by exceedingly good flowers, second in quality only to those at the late Royal Aquarium Show. Splendid blooms of W. R. Church were on view, together with M. Louis Remy, Florence Molyneux, Mrs. Coombes, and Miss Edith Pilkington, the latter being the premier Jap of the show, and exhibited by Mr. L. J. Newell, gardener to W. H. Dore, Esq., Branksome Park, Bournemouth, who was the chief prizewinner. There was a slight falling off in number of entries.

Mr. N. Molyneux, of Rooksbury Park, with Mr. H. Shoesmith, of Woking, judged the plants and cut flowers, and Mr. P. Isherwood, The Gardens, Criche, the fruit and vegetables. There were also classes for honey exhibits. The Mayor of Bournemouth opened the exhibition, and was supported by a number of the aldermen and councillors. The secretary to the society, pro tem., is Mr. C. W. Barrett, of Rosina, Drummond Road, Bournemouth, and has worked very successfully in his onerous position.

In the first division (open to all England), for thirty-six Japs, distinct, Mr. Newell, as we have already mentioned, led off with a good even set, the colour of the blooms very good, and size and finish both creditable. No other competed, however. For the twelve blooms, Sir John Groves' gardener (Mr. J. Collins) beat Mr. W. Squire, gardener to Col. C. M. Churchill, J.P., and the latter was alone for the twelve incurved, staging rather uneven blooms. Lady Isabel was the premier incurved, from the Rev. C. H. Burrows. In the local classes (second division), for a group of Chrysanthemums, Mr. Newell again was

first. The principal other prizetakers were Messrs. W. Squires, G. Barge, F. P. Telfer, T. J. Hankinson, G. James, Rev. C. H. Burrows, and Dr. H. G. Lys. The floral decorations formed quite a large feature of the show.

### Witney, Oxon, Nov. 4.

The annual exhibition of Chrysanthemums, fruits, and vegetables was held on November 4 at the Corn Exchange. The number of entries in the Chrysanthemum classes was not so large as last year, but in the classes for fruits and vegetables there were more entries. Two fine groups of Chrysanthemums were staged by Messrs. Felton and Batt. Mr. J. G. Ravenor staged twenty-four distinct Japanese blooms of exceptional merit. The magnificent fruits (Apples and Pears) staged by Mr. C. Walter, of Wantage, were specially admired. The collections of vegetables were keenly contested, and some excellent productions were staged. The leading prizewinners were Mr. J. White, Mrs. Pembrey, Mr. C. D. Batt, Mr. C. W. Early, and Mr. Gask. Primulas were exceptionally good, the leading prizes being taken by Messrs. Batt, Jacobs, Early, and Foreshow. The non-competitive collection of forty dishes of Apples from Mr. Wastie, Eynsham; and Marie Louise and Princess of Wales Violets from Mr. John Akers, Stanton Harcourt; and the group of plants from Eynsham Hall, staged by Mr. Anderson, were greatly admired. The success of the show is due to the energetic secretaries, Messrs. Felton and Hayter, and a hard-working committee.

### Cambridgeshire Horticultural, Nov. 5 and 6.

The Chrysanthemum, fruit, and vegetable exhibition of this society was held in the Corn Exchange, Cambridge, on November 5 and 6. The show was an excellent one, and the prizes were keenly competed for.

**CHRYSANTHEMUMS.**—The first prize for a group of plants in pots arranged in a circle 12ft in diameter was carried off by A. Matthews, Esq., 10, Trinity Street. The only other entry came from Miss Newman, Station Road, who was awarded the second prize. In the classes for pot plants, Mr. G. Willers, of Trumpington Road, and Ald. W. Bond, J.P. (gardener, Mr. H. Edwards), were winners of the first and second prizes respectively, except in the class for one single Chrysanthemum, when Ald. W. Bond was first and Mr. Willers second, there being no other competitors for pot plants.

For cut flowers, which were well grown, and included some good popular sorts, and not a few novelties, Ald. W. Bond, J.P., was again very successful, gaining four first prizes and three second prizes, closely followed by A. J. Thornhill, Esq. (gardener, Mr. F. Lockie), who obtained three first and two third prizes. E. B. Foster, Esq., J.P., Trumpington (gardener, Mr. Forbes), was awarded two first prizes and one third. Messrs. A. Matthews, J. Linton, A. W. Marshall, J.P., L. D. Stables, and Briscoe were the winners of the minor prizes for cut blooms.

**Special Prizes (Open to All England).**—For thirty-six Japanese blooms, distinct, Ald. W. Bond (gardener, Mr. H. Edwards) was awarded first prize, and E. B. Foster, Esq., J.P., Trumpington, won the second prize. In the class for six vases of Japanese, in distinct varieties, three blooms of one variety in each case, Ald. W. Bond, J.P., was again first, and A. W. Marshall, Esq., second, Mr. J. Matthews being third.

The premier bloom in the show (Japanese) was won by E. B. Foster, Esq., the variety being Mr. H. Weeks. The premier incurved bloom was won by A. J. Thornhill, Esq. (gardener, Mr. F. Lockie). The pompon and Anemone-flowered varieties were not much in evidence.

**FRUIT.**—Apples, Pears, Grapes, and Tomatoes were well represented, the Apples especially so. The size and colouring were said to be superior to those shown recently at the Crystal Palace, but, of course, some weeks have elapsed since the latter show was held. The special prize for Apples and Pears (open to all England), thirty dishes all distinct, went to Viscount Clifden, Lanhedock, Bodmin (gardener, Mr. W. J. Snell), and the second easily to Mr. J. H. Ridgewell, The Gardens, Histon, Cambs.

**VEGETABLES** were represented by well-grown examples of the leading sorts. Brussels Sprouts, a good variety, raised by Mr. J. H. Ridgewell, Histon, Cambs, and named Cambridge Champion, is a good sort, with firm buttons. Ailsa Craig Onion was the best variety shown, and Turnip Snowball was the best of this culinary product. Potatoes were in great variety and good form, Webb's Empire and Gordon Matthews especially so. A small dish of green Peas, not for competition, created surprise.

P. L. Hudson, Esq., Pampisford, Cambs (gardener, Mr. J. Kirkpatrick), received an Award of Merit for a non-competitive group of Orchids and foliage plants, which were tastefully arranged near the entrance.

Messrs. Isaac House and Son, Bristol, staged some beautiful single and double Violets. The judges were Messrs. G. Gordon, J. Meyers, and G. Wythes. The secretary, Mr. Arthur Matthews, and his assistant, Mr. Fordham, did all in their power to render the show a success.

## Cardiff, Nov. 5.

The annual autumn exhibition was held in the Park Hall—a most suitable site—and was, from a horticultural point of view, a great success. Throughout the show much high-class culture was prominent. In no section was this more plain than the classes devoted to cottagers and amateurs. In the former section incurved varieties of *Chrysanthemums* were simply marvellous productions. C. H. Curtis, for example, was here staged quite equal to any blooms of this variety staged at the late show of the N.C.S. in London. Trained plants were of a high order of merit, a similar remark applying to floral work, wreaths, bouquets, &c. Mr. Julian, Chairman of Committee, with Mr. Gillett, worked hard to make the show what it undoubtedly was—a success. Cut blooms were the most important feature of the show.

**OPEN CLASSES.**—The leading prize was £6, offered for twenty-four Japanese distinct, for which four competed. Mr. Drake, Cathays Terrace, Cardiff, somewhat easily secured the leading award with a stand of remarkably even, fresh, full-sized blooms of the following varieties:—Back row: Mrs. J. Lewis, T. Carrington, Anstrale, Madame Herrewé, Rev. W. Wilks, Madame G. Bruant, Le Grand Dragon and Madame Carnot. Middle row: Mrs. A. Barratt, M. Hoste (very fine), M. Chenon de Leché, W. R. Church (rich), Madame L. Remy, Millicent Richardson, Mrs. Coombes and Mrs. Mease. Front row: Miss Nellie Pockett, Matthew Smith, Mrs. Barkley, M. Louis Remy, Vivian Morel, Mrs. G. Mileham, C. J. Salter and General Buller. Mr. J. Howe, gardener to G. Williams, Esq., Manor House, Cardiff, was a good second with blooms a trifle smaller. W. R. Church, H. Stowe and Bessie Godfrey were noteworthy in this stand. Mr. C. Ritchings, gardener to the Misses Baird, St. James, West Malvern, was third.

For twenty-four incurved three competed, the best—an even level set, neatly set up—coming from Mr. Drake. Lady Isabel, C. H. Curtis, Dorothy Foster, Ialene, Hanwell Glory, Nellie Southam, Louisa Giles, Yvonne Desblanc, Nellie Threlfall, Miss Annie Hills and Mrs. H. J. Jones were the most conspicuous. Mr. Ritchings followed closely. Globe d'Or, Lady Isabel and Rose Owen were very fine in this collection. Mr. H. Townend, gardener to H. Pitt, Esq., Abergavenny, third.

Four competed in the class for twelve Japanese, Mr. Townend easily securing the premier award with full-sized even blooms, of which the following were the most conspicuous: Lily Mountford, Nelly Towers, Mrs. J. Bryant and Lord Ludlow. Mr. R. Milner, gardener to Miss Talbot, Margam, second. Mr. J. Howe third.

**LOCAL CLASSES.**—For twenty-four Japanese in not less than twelve varieties there was a stiff competition, and excellent blooms staged. Mr. E. A. Parsons, gardener to Mrs. J. D. Gunn, Newport Road, Cardiff, secured the leading award with a collection containing remarkably handsome blossoms of Mrs. J. Lewis, W. R. Church, Madame Carnot, Lord Ludlow, M. Louis Remy, and M. Chenon de Leché. Mr. J. J. Graham, gardener to A. T. Stephens, Esq., Penarth, was a close second; Mrs. G. Lewis in this stand was adjudged the premier bloom of the show. Mr. H. A. Allen, Penarth, third.

Mr. Graham succeeded in winning the first place for twelve Japanese, very closely followed by Mr. A. F. Hill, 10, Oakfield Street, Cardiff, who staged remarkably fine examples of popular varieties. W. R. Church in this stand winning the Wells Silver Medal. Mr. T. Malpas, gardener to Dr. Lynn Thomas, Cardiff, a close third. Mr. Parsons won the first prize for twelve incurved with neat examples of leading varieties. For six blooms any one white variety Mr. Graham staged Mrs. J. Lewis, securing the coveted award, Mr. Parsons following with the same variety. Six staged twelve Japanese: Mr. A. F. Hill first, Mr. H. A. Allen second, and Mr. A. H. Edwards third, all very close together in point of merit.

Cottagers' classes were remarkable for the excellence of the blooms produced. For six incurved, Mr. J. G. Jones, 41, Cecil Street, Cardiff, staged blooms of C. H. Curtis and Ma Perfection that would have been a credit to the Trophy Class blooms at the Aquarium in London. Mr. E. Jones, 122, Pearl Street, Cardiff, second.

No fewer than ten staged six Japanese distinct. Mr. W. H. Owens, 62, Salisbury Road, Cardiff, won first place with Mrs. J. C. Neville and E. Carpenter, remarkably good. Mr. E. U. Phillips, Canton, a close second. Single flowered varieties were capitally staged. For six bunches distinct, three sprays of each, Dr. T. Wallace was an easy first with attractive blooms. Mr. A. T. Stephens second.

In the cross and wreath department, Mr. W. Treseder was almost unapproachable, securing the leading awards for the best wreath, cross, ladies' spray and bridal bouquet, all of the highest merit. Mr. Ralph Crossling, Penarth, secured the leading award for bouquet of *Chrysanthemums* with a choice effort composed of *Source d'Or* entirely, with Ferns, &c.

Plants were not numerous, but remarkable in point of quality. For two dwarf trained specimens, incurved, Mr. T. Binden, gardener to Dr. T. Wallace, was the only competitor.

The two plants were C. H. Curtis, about 3ft in diameter, one carrying thirty-four specimen blooms, the other twenty-three, even larger than those on the former plant. The foliage, too, was remarkably healthy and abundant. With a marvellous plant of Miss Rose, fully 4ft in diameter, and literally smothered with flowers, Mr. Binden secured the leading award for specimen single flowered variety. In the open class for a group of *Chrysanthemums*, Mr. Treseder was the only competitor, staging plants carrying good blooms and not too crowded.

Local classes were better filled. Mr. W. Hatherdale, Roath, won for a group to fill a space of 50 square feet. The plants were capitally grown and arranged. Mr. James Howell, Cardiff, second. Mr. W. H. Owen winning in a smaller class with a meritorious exhibit. Non-competitive exhibits were numerous and interesting. Mr. J. Basham had a remarkably fine display of hardy fruit, Mr. W. Treseder Cactus Dahlias, Mr. Stephen Treseder Roses, and Mr. J. Cypher, Cheltenham, Orchids.

## Corn Exchange Chrysanthemum Show.

This took place on the 10th inst., and, as usual, was held in an upper room of the Restaurant adjoining the Corn Exchange in Mark Lane, London. This exhibition arose out of a feeling of rivalry among members of the Corn Exchange who cultivate *Chrysanthemums*. The schedule contains but nine classes. The first four are open only to members of the corn trade only; there are four others open to non-members who are amateurs; and there is a ninth class for a vase of six cut blooms. The blooms are arranged ready for judging by 11 a.m., and as soon as the awards are made exhibitors and others are admitted; and at half-past three the blooms and such other exhibits as may be sent are sold by auction for the benefit of the Corn Exchange Benevolent Society, and a goodly sum is thereby obtained for this deserving charity.

In the classes open to members of the Corn Exchange the principal ones were Mr. Wm. R. Clarke, the treasurer, and Mr. F. W. Smith, the former being the most successful, as he obtained the first prize for twelve distinct Japanese varieties, his gardener, Mr. F. King, staging well-developed blooms of Madame Gustave Henry, M. L. Remy, M. Chenon de Leché, Australie, G. J. Warren, Sunshine, W. R. Church, Swanley Giant, Mrs. G. W. Palmer, &c. Mr. F. W. Smith, Weybridge (Mr. T. Buckmaster, gardener), was a close second. He had good blooms of Henry Stowe, Madame Carnot, G. J. Warren, Le Grand Dragon, Nellie Pockett, Sir H. Kitchener, W. R. Church, Mrs. G. Mileham, &c. With twelve blooms, distinct varieties, thereby meaning any type, Mr. W. R. Clark was again first, having four good incurved blooms, viz., Madame Ferlat, Lady Isabel, *Chrysanthemiste Bruant*, and Madame E. Roger; and such fine Japanese as Mrs. Mease, Pride of Exmouth, Mrs. W. Cursham, M. L. Remy, &c. Mr. F. W. Smith was again second, having all Japanese. With six blooms of Japanese Mr. Clark gained a third success, staging capital examples of Lord Ludlow, Mrs. Barkley, Mrs. W. Popham, Mrs. G. W. Palmer, Australie, and Le Grand Dragon. Mr. F. W. Smith was again second, also with good blooms. With six blooms of any varieties Mr. Clarke gained his fourth first prize, staging once more good blooms, and Mr. F. W. Smith was second.

In the division open to non-members of the corn trade there were seven competitors in the class for twelve Japanese, the first prize being taken by Mr. R. Kenyon, Monkham, Woodford, who staged finely developed examples of Australie, Lord Ludlow, Lily Mountford, M. L. Remy, Mafeking Hero, Sensation, Mrs. G. Mileham, J. R. Upton, W. R. Church, Mermaid, M. Chenon de Leché, M. Hoste, &c. Mr. F. S. Holland (Mr. T. Stevenson, gardener) was second with good blooms of Madame G. Henry, Lily Mountford, Mrs. Harry Emmerton, Mrs. T. W. Pockett, Mrs. H. Weeks, Mrs. Greenfield, Mrs. G. Mileham, &c. With twelve blooms, distinct varieties, Mr. Holland was again first, staging four very fine incurved varieties—*Chrysanthemiste Bruant*, Mrs. H. J. Jones, Ialene, and Hanwell Glory; and such Japs as W. R. Church, Australie, Mrs. G. Mileham, M. L. Remy, Soleil d'Octobre, &c. With six blooms of Japanese Mr. Holland was again to the fore. He had, in good form, M. L. Remy, Australie, Miss C. Pilkington, Mr. T. Carrington, Matthew Smith, and Madame L. Remy. Mr. R. Kenyon was second, his leading blooms were M. Chenon de Leché, Sensation, Henry Weeks, and Mrs. Barkley. With six blooms of any varieties the first prize was taken by Mr. Holland, with the following incurved:—Mrs. H. J. Jones, Dome d'Or, Globe d'Or, Lady Isabel, M. Desblanc, and Miss A. Hills, all in good character. Mr. H. Ferguson came second with five Japs, chief among them W. R. Church, M. L. Remy, and C. J. Salter. The best vase of six blooms open to all came from Mr. F. S. Holland, and Mr. F. W. Smith was second.

Among miscellaneous exhibits were ten pots of charming *Cattleyas* from Mr. D. H. Grimsdale; a lovely bouquet of Orchids, Lilies, Roses, &c., H.T. Liberty being conspicuous among the latter; and a decorated car, a very good piece of work indeed, from Messrs. M. Longman and Co., Mark Lane.

A silver bowl, offered for the best twelve blooms in the classes

open only to the members of the Corn Exchange, was awarded to Mr. W. R. Clarke, for his twelve first prize Japs in class 1, and a silver cup for the best twelve blooms in the classes open to non-members was awarded to Mr. F. S. Holland, for his fine stand of eight Japs and four incurved in class 6.

### Southampton, Nov. 4.

Quite one of the best of the many autumn exhibitions held in the Victoria Hall was that which took place on the date named. The competition generally was of a keen order of merit; the exhibits close in point of quality.

**OPEN CLASSES: PLANTS.**—For the best collection of Chrysanthemums arranged in a limited space, Mr. C. Hosey, gardener to J. C. E. D'Esterre, Esq., Elmfield, Southampton, was first prizetaker with dwarf plants carrying good blooms. Mrs. Barkley, Mrs. Weeks, and N.C.S. Jubilee were especially noticeable. Mr. B. Henley, Masonic Hall, Woolston, was second. Mr. T. Hall, gardener to Sir S. Montagu, South Stoneham House, third. Plants suitable for conservatory decoration were well shown. For four Mr. C. Hosey won with good examples of Charles Davis, R. Hooper Pearson, T. Carrington, and Miss Alice Byron. Mr. C. Dymott, florist, 50, Millbrook Road, Southampton, was second. Bush plants, naturally grown, were numerous and good, Mr. Dymott winning from Mr. C. Hosey, who followed closely.

**CUT BLOOMS.**—The principal class was that for twelve varieties Japanese, three blooms of each, staged in vases, for which the Victorian Challenge Trophy was offered, along with a substantial money prize. Three competed, the best coming from Mr. G. Hall, gardener to Louisa Lady Ashburton, Melchet Court, Romsey, with really good examples of Thomas Giles, William Keylock, Mrs. G. Mileham, Le Grand Dragon, Marquis de Venosta, Mrs. L. Remy, Australie, Madame Herrewége, T. Carrington, Mrs. J. Lewis, Mrs. J. Bryant, and Mrs. Weeks. Mr. L. Dawes, gardener to Mrs. Ogilvie, Hambledon, was an uncomfortably close second, his best blooms being Mrs. Barkley, Sir H. Kitchener, Jane Molyneux, Pride of Madford, Miss Alice Byron, and Phœbus. Mr. C. Hosey was third.

For twenty-four Japanese four competed, the best coming from His Majesty the King, Osborne (gardener, Mr. T. Nobbs), with Mrs. E. Barker, Mrs. J. Bryant, M. Louis Remy, Vivian Morel, Jane Molyneux, Mrs. W. H. Lees, Madame Desblanc, Anstrale, Charles Davis, Mrs. Barkley, Guy Hamilton, Mrs. Coombes, Mrs. C. H. Payne, J. R. Upton, M. Chenon de Leché, Le Grand Dragon, Mrs. W. Mease, H. Payne, and Lady Hanham, Mr. G. Hall being second. Mr. J. Wasley, gardener to J. B. Taylor, Esq., Sherfield Manor, Basingstoke, was third. Five competed in the next class, that for eighteen Japanese, making a full display. The prizes went in the same order as in the former class.

For twelve Japanese Mr. Dawes won easily with fully developed examples of Mdle. Marie Hoste, Mrs. Coombes, M. P. Rivoire, Alice Byron, Lord Salisbury, E. Molyneux, Pride of Madford, M. Gustave Henry, Sir H. Kitchener, Mrs. G. Mileham, Mutual Friend, and Phœbus. Mr. Nobbs second. In the class for twelve incurved Mr. P. Hall won easily with medium-sized examples of Topaze Orientale, Globe d'Or, Yvonne Desblanc, Ada Even, Miss D. Foster, C. Crooks, Lady Isabel, Nellie Threlfall, Baron Hirsch, C. H. Curtis, Mrs. R. C. Kingston, and Louisa Giles. Mr. J. Love, Park Road, Cowes, Isle of Wight, second. In this stand, was accorded the premier award for an incurved bloom. Mr. E. Brown, Alma Road, Southampton, won for twelve Japanese incurved, with typical examples of this section. Mr. G. Hall second.

In the classes devoted to gentlemen's gardeners and amateurs there was a bold display of really fine blooms. For eighteen of any kind, and not more than two of any one variety, four competed, the best coming from Mr. E. Brown. Noticeable in this stand were Mrs. Mileham, W. R. Church, Mrs. Weeks, Calvat's '99, M. Chenon de Leché, Vivian Morel, Alice Byron, and C. Davis. Mr. M. Hodgson, Morton House, Kingsworthy, second. Amongst seven competitors for twelve blooms Mr. Brown again won with varieties similar to what he staged in the previous class. Mr. Tragett, Awbridge Danes, Romsey, second. In the class for four varieties Japanese, three blooms of each, staged in vases, Mr. Brown again won first prize with really fine examples; second, Mr. H. E. Sugden, Ingersley, Chilworth. The premier Japanese bloom was Miss Alice Byron, belonging to Mr. J. Dawes.

Miscellaneous plants arranged for effect were not numerous. Mr. E. Wills, The Nurseries, Winchester Road, Southampton, was first; Mr. T. Hall, second.

**OPEN TO LADIES ONLY.**—For the most tastefully arranged vase of Chrysanthemums, foliage, grasses, &c., Miss Minnie Snellgrove, 10, Oxford Road, Southampton, was accorded premier place for a charming exhibit. Mrs. Jeffrey, Nursling, Southampton, second. Five competed with a basket of autumn leaves and berries grown cut of doors, and as all were tastefully arranged a good effect was produced. Miss Wadmore, Brook House, Basingstoke, was the most successful with a charming exhibit; Mrs. Jeffreys second.

Fruit was plentifully contributed. Space, however, forbids more than a mere mention of the classes. Five competed for three distinct varieties of Grapes. Mr. J. C. Eastwell, gardener to E. C. Walker Munro, Esq., Rhinefield, Brockenhurst, was first with Alnwick Seedling, Muscat of Alexandria, and Gros Guillaume. Mr. W. Mitchell, gardener to J. Willis Fleming, Esq., Chilworth, second. Mr. T. Hall, third. Apples were numerous and of excellent quality. For four varieties dessert Mr. T. Hall won the leading position with an excellent exhibit. Mr. H. Osman, The Vineries, West End, was second. No fewer than nine competed for four varieties kitchen Apples. Here Mr. T. Hall was again the most successful.

The arrangements were, as usual, of that high character which always is in vogue here, Mr. C. S. Fudge, Secretary, having everything in place at the right moment.

### Newport, Nov. 6.

In the Gymnasium, the fourteenth annual autumn show was held on the date named. The entries were not quite so numerous as in some years past owing to the unfavourable weather experienced. Still, they were plentiful to make a pleasing display. The arrangements were quite of the right order in the hands of a practical committee so ably led by Mr. F. Turner, hon. secretary.

Open classes were not numerous. For the best group of Chrysanthemums interspersed with foliage plants Mr. J. Pegler, gardener to H. J. Davis, Esq., was the most successful, winning with plants carrying substantial blooms and good foliage, all tastefully displayed. Dr. Thomas was a good second.

Bush grown and dwarf trained plants were sparsely shown. Cut blooms were numerous and good. The principal class was that for twenty-four Japanese in not less than twelve varieties, for which a challenge cup and a substantial money prize were offered. Three competed. Mr. J. Duff, gardener to Mrs. Williams, Newport, was an easy prizetaker with heavy fresh blooms; especially good was Australie, Madame Carnot, Simplicity, Matthew Smith, Mrs. J. L. McKellar, Phœbus, Calvat's '99, Mons. Louis Remy (extra fine), Mrs. J. Bryant, E. Perkins, Madame L. Remy, Madame G. Henry and Vivian Morel. Mr. J. J. Graham, gardener to A. T. Stephens, Esq., Newport, was second with typical examples of Mrs. Barkley, W. R. Church, Mrs. Mease, Calvat's Sun, Pride of Madford, and Mrs. J. Lewis. Mr. G. W. Drake, Cardiff, third. In the class for twelve Japanese distinct, Mr. J. Duff again won premier position with smaller examples than he staged in the former class. Mr. Greenfield, Nellie Pockett and Edith Perkins were noteworthy. Mr. G. Richardson, gardener to Sir H. M. Jackson, second.

In the local classes the competition was much keener. Mr. R. Long, gardener to W. J. Dawson, Esq., won for a group of Chrysanthemums. Colonel Wallis second, Mr. Phillips securing a first prize card for a group of miscellaneous plants with quite an effective exhibit of Orchids, Palms, Ferns and Crotons. Colonel Wallis second.

For twelve Japanese blooms five competed, making a capital display. Mr. A. T. Stephens first, Sir W. Jackson second, and the Rev. W. M. Willett third. Smaller Chrysanthemum classes and miscellaneous plant classes were well filled. Apples and Pears were plentifully staged. Space, however, forbids details.

### Birmingham Gardeners'.

Mr. F. W. E. Shrivell, of the Experimental Farm, Golden Gate, Hadlow, Tonbridge, was responsible for a very interesting and suggestive lecture recently before the members of this association, relating, as it did, to the influence of nitrogen on the Leguminosæ and Brassicæ. Lantern slides were used to illustrate the comparative results of crops and vegetables treated with stable or farmyard dung alone, on the addition of chemical fertilisers; also with the latter by themselves. The combination, however, of these components produced the greater results. For Potatoes animal-litter manure was considered essential, with or without the co-operation of artificials, serving, as it does, for the conservation of moisture in the soil and the necessary elaboration of the chemical agencies. As Mr. Shrivell observed, the experiments at Golden Gate are carried out with a view of ascertaining the economical value of heavy or light dressing of stable manure; also the possibility with regard to the economy of replacing the dung in some measure by chemical fertilisers. Further, they were meant to prove the quantity of nitrate of soda to be used with or without phosphates and potash, and the advantage, if any, of dispensing with dung altogether, and of substituting for it chemical fertilisers. The results show that, while a certain quantity of dung is essential, its use is often highly extravagant, and that it may, to a certain extent, be most profitably supplanted by various artificial manures. The lantern-slide illustrations were convincingly demonstrative of the judicious application of the chemical stimulants over that of stable dung alone. Various questions were satisfactorily answered by the lecturer, and in the discussion Messrs. W. B. Latham (the chairman), W. Gardiner, Walter Jones, C. R. Bick, C. H. Herbert, W. Spinks, and J. Wheeler took part.

## Gadding and Gathering.

"HERE AWA', THERE AWA'."

### Trees and Shrubs: The Planting Season.

One has active times at present "amunning" with the "Mummers," and gadding with the tree and shrub men. The gaddings are strictly to the point, and severely utilitarian, for multum in parvo is the distinguishing motto of the passing age.

Someone desires a short list of dwarf and compact growing evergreen shrubs, and I venture to name the following, which Mr. John Russell, of Richmond Nurseries, in Surrey, has nice stocks of at his numerous well-ordered grounds:—*Osmanthus Aquifolium* and its variety *ilicifolium*, a very attractive shrub that never grows ungainly, and generally slow but sure. It much resembles a fine-leaved bushy Holly, and has a chocolate-black colour of foliage. It furnishes an admirable covert plant, though it could not be planted on a large scale, yet in ornamental parts of the ground, where covert may also be desirable, it is worthy of consideration.

Another fine shrub is *Phillyrea decora*, perhaps one of the handsomest evergreens than any gardener could plant, and is highly recommended by Mr. Russell. It forms a compact, yet withal pleasingly developed shrub, with leathery, dark green, oblong, and smooth leaves, 5in to 6in in length. The plants can easily be kept in hand by a judicious use of the pruning knife every few years. *P. buxifolia* has very small leaves and twiggy growth; and there are also *P. angustifolia*, *latifolia*, *P. l. ilicifolia*, and the very handsome *P. Vilmoreana*, each of which has qualities.

*Olearia Haasti* is continually being planted, and no one could desire a hardier subject. I have seen it flourishing—which means that it was thoroughly established and happy—in bleak, wind-swept beds around Edinburgh, and in half-shaded corners of gardens, and flowers came year after year. The flowering propensity indeed almost constitutes a fault, for the plants in some cases expend their whole strength in floraison. In the autumn the downy heads of seeds turn brownish, and not everyone admires the appearance of them. The foliage is hard and small, but pretty on account of its bright greenness and silvery reverse. For town and smoky districts, equally for the remote parts of the country where shelter is not a feature, this shrub succeeds.

The numerous varieties of *Euonymus japonicus* must not be omitted from the present list. They are *E. j. medio-pictus aureus*, with narrow green leaves, and stems and centre of foliage bright golden; *latifolius albus variegatus*, leaves broadly margined with white, and a compact grower; *ovatus aureus*, the favourite golden coloured, broad leaved variety, and *argentea variegata*, with broad green foliage, margined with white, very largely planted. The type, *E. japonicus*, is very hardy, with leaves of a shining dark green. It is largely used for beds and for close undergrowth plantations, also for loose hedge screens in front of villa front gardens. Small plants are admirable for winter bedding and for window boxes. The white and green variegated creeping variety, so largely employed to carpet what might be bare spots beneath trees, is *Euonymus radicans variegata*.

Confining the choice still to dwarf evergreens, what is better for planting on neglected shady spaces beneath tall trees or in similar areas than the Butcher's Broom (*Ruscus aculeatus*)? The erect shoots are closely set with sharply pointed, even-edged, and smooth little "leaves," of a very intense dark green colour. When the plants are entirely happy, these little eladodes, or leaves, bear tiny Liliaceous, head-like flowers on one of their surfaces. The plant demands scarcely any attention, and will grow on dry banks without showing signs of distress. Two or three feet is the usual height.

*Skimmia japonica* must also be included, but it is not a favourite shrub with many, having a very dumpy habit of growth. It is very hardy, berries well, and is useful amongst dwarf evergreen flowering shrubs. The various varieties of *Buxus*, or Box tribe, are employed where topiary art is practised, and at Kew one has a splendid lesson on how to use the different sorts effectively in one bed. The bed is a large round one, and is filled with *Buxus* only. These are set in circles from the centre to the edge, taller growing varieties in the middle and the pigmies toward the outside. Each circle consists of one kind of *Box*, and the contrast of colour is very satisfactory. The shears are lightly applied to the shrubs, so that their form is kept within the desired and prescribed limits, though without severe formality. There are plenty of kinds of *Buxus* at the Richmond Nurseries to choose from, and these plants might be made more use of, in such arrangements as that referred to.

One would like to individualise a number of other specially effective and useful shrubs along this line, but space is a precious quantity, and the notes require curtailment. The *Cotoneasters* are rambling growers, more suitable for walls than for the grounds. Some of them, however, form pretty bushes—such as *C. microphylla* and *C. m. thymifolia*. *C. horizontalis* may also

be named. The others are larger and freer, except probably *C. congesta*, but of it I cannot write. The *Elæagnus* are very useful—and the word useful here means that they are adaptable in the hands of the planter for a variety of positions and uses, all for ornament, however, in the garden or kept grounds and shrubberies. The *Andromedas*, like the *Rhododendrons* and *Vacciniums*, prefer, though they do not absolutely demand, a peaty soil. A calcareous tilth they do object to. *Berberis Darwini* and even *B. stenophylla*, also the *Mahonia* (*B. Aquifolium*), the latter particularly, are suitable for inclusion here. The *Aucubas* must not be omitted, and for exposed knolls or dry hillsides and banks, what is better than the golden flowered Double Gorse. Its vivid green shoots are pretty in early spring, and the intense mass of richest yellow rivals the sun's splendour during April and May. To the foregoing notes I would like to append selections of other shrubs of taller growth, and having an evergreen character.

## Seedling Nectarines.

From the Editor of the *Journal of Horticulture* I have been favoured with two seedling Nectarines of Mr. W. Strugnell's raising at Rood Ashton Gardens, Trowbridge, Wilts, for opinion, and, as they have some distinct features, are figured in both fruits and leaves.

No. 1 seedling, fig. 1, A and B, was scarcely ripe when received—October 3, 1902. Mr. Strugnell, in a note, accounted for this through wasps being so destructive and only two fruits left, and it was kept until the 13th of that month, when it was sketched and eaten, the following being the description:—

Fruit, medium sized, almost round, slightly wider than in height, depressed at the apex, and with a wide shallow suture. Skin, pale green at the base and shaded side, entirely covered with dark purplish red next the sun. Flesh greenish, with a tinge of red next the stone, from which the flesh parts freely, melting, juicy, rich, and highly flavoured. Leaves serrated, without glands. Mr. Strugnell has obliged with the following replies to my queries through the Editor:—
